Accepts in Whole or Part Reports of Five Standards Divisions—Seven Report Progress—Valuable Papers

By J. Edward Schipper

CAPE MAY, N. J., June 26.—Today ended the programme of the 4-day convention of the Society of Automobile Engineers, held at the Hotel Cape May. Combining a list of important business and professional sessions with an intermixture of successful social and entertainment features the Summer meeting of 1914 has been a success which has rarely been surpassed in the history of the society.

While the attendance this year of members and their families hovered closely around the 300 mark, whereas in previous Summer sessions held in the Middle West, the attendance has been fully 50 per cent. greater, yet for pithiness and importance of discussion and in the value of the papers read, the meeting was all that could be desired from a business and social standpoint. Not a drop of rain marred the perfect weather of the 4 days, and full advantage was taken by all those present of the beautiful seashore site selected as the meeting place.

The three broad lines of endeavor of the society, namely: Standardization, research and the promotion of social acquaintanceship, each received its full share of attention from the members who attended. Standardization work was represented by the reports from twelve divisions of the Standards Committee, which met on Tuesday, the first day of the convention, and which forwarded the results of their work to the society at large during the session which followed. Nine reports of progress or reports on definite standards suggested were put up before the meetings for final acceptance. The result of the discussions on the reports of these divisions were the adoption of several new standards which will not be put into the hands of engineers through the medium of the S. A. E. data sheets.

The work of research was represented by a programme of thirteen papers on varied subjects. These papers which covered timely topics such as a study of the tire situation from both the passenger and truck standpoint, electric starting, lighting and ignition devices, the desirable features to be incorporated in the ideal car, etc., were not only of the highest educational value themselves, but provoked discussion which

Group of those present on the front veranda of the Hotel Cape May on the last day of the session

Henry Souther, Standards Chairman

will make a valuable addition to the transactions of the society. In the instance of the papers on tires the work of the pleasure car wheels division of the standards committee was closely followed—and the papers served as an excellent educational medium to clearly bring out what is required of the standards committee in their adoption of higher dimensions and rim requirements.

The same holds true of the paper giving a general summary of the truck tire situation, and that on tap drill sizes and causes of stripped threads. These two papers follow the work of the truck standards and miscellaneous divisions, which are covering respectively the requirements of truck tires and the fit in tapped holes.

The social end of the programme at the convention furnished the relaxation essential to an efficient consideration of the entire business programme. In addition to all that the hotel, especially designed to meet the requirements of those engaged in the pursuit of pleasure, could afford, there were the sports and amusements provided by the entertainment committee of the society. Never before had sports been given such an amount of study as in this summer meeting, and the result was that they were more heartily entered into and more thoroughly enjoyed than in previous summer meetings. Outside of the swimming, dancing and entertainments by the sections of the society during the evenings of the convention, there was at the close of the business session a complete programme of athletic field sports for which the sports committee had provided a series of handsome prizes. This arrangement induced a spirit of friendly competition and went far towards making the meeting the all-around success that it was.

When the midsummer meeting of the society opened at 2 P. M. Wednesday in the ballroom of the Hotel Cape May, with President Leland presiding, the Mayor of Cape May, introduced by Coker F. Clarkson, secretary of the society, extended the freedom of the city to the guests in the presence of an interested audience of 200 engineers. After the close of President Leland's address, which was reported in last week's issue of THE AUTOMOBILE, Mr. Clarkson read a letter from T. B. Browne, President of the British Institution of Automobile Engineers, presenting the society with a beautiful reading table as a pleasant reminder of the visit paid by members of the institution on the occasion of the joint midsummer meeting of the two societies held on board the City of Detroit III, last summer, while cruising the Great Lakes. The society by a unanimous rising vote passed a resolution to forward a suitable reply to the English engineers.

Howard Coffin, of the Hudson company

The report of the treasurer, Hermann F. Cuntz, was read by Mr. Clarkson. The report showed total receipts of $31,691.63; $2,412.95 of this was in cash on hand and in bank and $29,278.68 in the form of receipts. The disbursements amounted to $30,127.76, leaving a balance of $1,563.87.

The report of the tellers of election showed a gain in membership since the January meeting of 207. The increase in actual members of the Society number 76, increase in associates 106, in Juniors 15, affiliates 7, and departmental 3. This shows the membership of the Society to be steadily growing.

Of considerable importance to the Society is the adoption of the proposed amendments to the constitution as determined at the January, 1914, meeting. The two articles which caused the most discussion were those dealing with the composition of the nominating committee. After considerable debate an entirely new article was formulated by which the nominating committee will have seven members, three of whom will be elected by the sections of the society, each section having the power to choose one member of the committee, and the four other members will be elected by the Society at large. In the event of there being more than three sections, the three having the greatest membership shall have the choice of the three members of the committee to be elected by the sections.

Another important feature brought up at the business end of the meeting before the regular professional session was started was the question of student enrollment. It was suggested that a paragraph be added to that article of the constitution which outlines the power of the council to authorize the organization of sections of any or all grades of membership, providing that bona-fide students of automobile engineering under 30 years of age may be enrolled as students and for the sum of $3 annually receive the S. A. E. Monthly Bulletin and be privileged to attend the meeting of the Society. To enter as a student, the endorsement of a member of the Society and the approval by the council is necessary. The object of the student enrollment, which is by no means a membership of any grade in the Society, is to foster the work of the Society in promoting the study of automobile engineering.

Next Meeting Place Considered

The question of the location of the next summer session of the Society was raised when Coker Clarkson read an invitation from the Panama-Pacific Exposition officials to hold the next summer meeting of the Society in San Francisco. This did not seem to strike a popular keynote, however, as it was felt that the value of the next meeting would be considerably lost through small attendance if the meeting were held on the Pacific coast. It was stated that the work of the Society is too valuable to have a single session lost in this manner, at this active period in the industry.

An invitation from the Detroit Board of Commerce was also

presented and while the hot weather would doubtless interfere with a meeting held in the actual city of Detroit during the month of June, it was felt by many of those present that the Detroit River would make an excellent starting point for a cruise among the thirty thousand Islands in the northern part of the Great Lakes, and the suggestion of chartering the City of Detroit III as a floating hotel seemed to meet with considerable favor. It was finally decided to secure the suggestions of different members and incorporate them in a circular letter to be voted upon by the voting members of the society.

On Thursday evening the semi-annual banquet was held and this year it was graced by the presence of the ladies of the party. The banquet was tendered by the management of the hotel and was attended by all the members of the party. After the banquet, Orrel C. Parker gave a lecture on the coming European trip and by means of stereopticon slides and moving pictures toook his audience through the various countries to be visited by the Society of Automobile Engineers on their European trip, which starts next October.

Five reports submitted by the Standards Committee to the Society at large were accepted either in whole or in part. The report of the Iron and Steel division, presented by Henry Souther, chairman of this division, was accepted in toto. In discussing the report of the division, Mr. Souther called attention to the importance of its work, and stated that where manufacturers claimed that they did not make use of S.A.E. steels they really did use these steels in many instances without knowing it; that is, they used steel of the same composition and practically the same heat treatment. He went on to say that the number of steels is diminishing each year and for this reason it has been possible to cut the number of steel specifications practically in half. The report of the division permits an increased allowance of .005 in the phosphorus and sulphur contents. This has been done for commercial reasons and there does not seem to be any real proof that this means a lowering of the quality of the steels used in automobile manufacture. If a manufacturer needs a high quality steel he has but to specify it, and now that the more reasonable limit .045 phosphorus or sulphur has been adopted it may be expected that the steel maker will rigidly abide by it.

Papers Provoke Discussion

The papers on tires by E. R. Hall and J. E. Hale, experimental engineers for the Goodyear Tire and Rubber Co., on starting, lighting and ignition devices by A. D. Libby of

Winners of prizes. Left to right—J. Edward Schipper, THE AUTOMOBILE, all-around championship; S. L. Murfey, Grant Lees Gear Co., aquatic championship; Frank Martin, Stewart-Warner Co., fat men's race; R. H. Combs, Prest-O-Lite Co., bowling

the Splitdorf Co. and the Electric Transmission for Motor Cars by J. B. Entz of the White company, proved to be the prize discussion producers. These discussions, which are reported in part in this issue, showed the keen interest with which developments in the tire situation and in the gasoline-electric plant are followed. The discussion after Mr. Libby's paper entered a phase which seems to be uppermost in the minds of engineers of the present day, who are interested in the development of the electrical equipment of the automobile. This point is whether or not the 6-volt system or the 12-volt system is the better for all-around practicability on the automobile. The discussion did not show conclusively an advantage for either side.

The report of the Electrical Equipment division was another which was accepted in part. This report embodied a standard insulation test and also the recommendation that the single wire system be adopted as preferred practice. No debate was occasioned on the subject of the insulation test and this part of the report was carried unanimously. When it came to the single-wire system, however, this proved to be one of the richest sources of debate of the meeting. The one-wire design was opposed by many because they deemed it to be unsafe and by others because they felt that the use of fuses was objectionable. Both these points were strongly opposed by those in favor of the single wire. The adherents of the single-wire system stated that the contention that the system is unsafe is absurd and that its successful use on 60 per cent. of the new models alone argued against this claim. They also held that the use of fuses was not an objection. The matter was finally automatically tabled because fifty voting members of the society were not present at the time.

T. F. Harris, Twombly Motors; E. A. DeCampi, National Lead Co.; F. B. Pierson, National Lead Co.

The social side of the convention was an immense success. While the attendance was not so great as at some of the other summer meetings, the opportunity for a general good time was perhaps greater than ever before. That this was so was not a little due to the presence of the wives and families of many of the members. Bathing, tennis, golf and the hundred-and-one possibilities presented by the seaside environment were eagerly seized, in addition to the well-balanced programme of sports outlined by the entertainment committee. On Wednesday evening the sections of the Society entertained with original features of their own. The Metropolitan section produced a trial of a cyclecar driver, the Detroit section read a paper on a farcical ideal car and the Indiana section gave for the benefit of the members present a representation of an Indian trial in which other members of the Society were captured and tied to the stake in true Indian style.

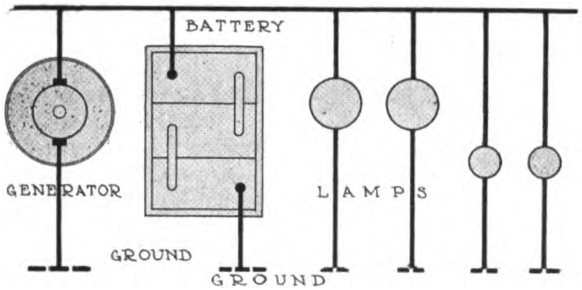
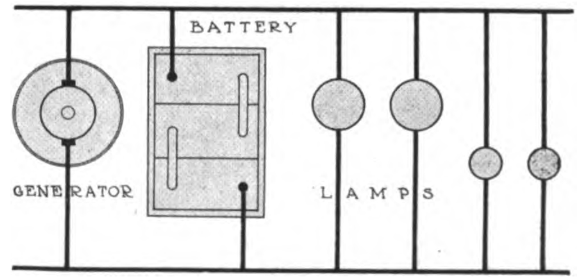
Single-Wire Versus Two-Wire System





"The single-wire system with grounded return shall be recommended practice"—Report of the Electrical Equipment division of the Standards Committee.

Bijur—"Motor car manufacturers use the single-wire system because it uses less wire."

Libby—"System should not be adopted because it is not safe; a ground may mean a fire."

Conant—"Single-wire system should be adopted because it is in line with modern trend."

Moscovics—"The art has not as yet developed to a sufficient degree to recommend it."

Fergusson—"We have given up the two-wire system because we had trouble and use one wire."

Lloyd—"It will be easier to adopt this measure now than it will be a year from now."

Towle—"Strongest objection to the one-wire system is its lack of fire safety."

McMurtry—"The issue should not be delayed; heavy installations are using one wire."

THE fifth report of the Electrical Equipment division brought up the warm debate that was confidently expected on the respective merits of the one and two-wire systems. In spite of the lateness of the hour the question was argued pro and con and finally tabled after an undecisive vote, since there were not fifty voting members present. The report of the division follows:

1—All insulating material used in connection plugs, sockets and similar devices of electrical apparatus for use on gasoline automobiles shall be capable of withstanding for thirty minutes a temperature of 300 deg. F.

2—The single-wire system with grounded return shall be recommended practice.

The first part of the report of the Electrical division regarding the tests on insulation was passed without comment upon a motion by R. McA. Lloyd. The second part, however, on adopting the single-wire system as recommended practice proved the cause of the warmest debate of the session.

Three letters from Leonard Kebler, representing the Ward Leonard company; W. E. Winship, of the Titan Storage Battery company and the United States Lighting and Heating company, each protesting against the recommendation, were read.

The letter from the U. S. L. company follows:

"The Electrical Equipment division of the S. A. E. will submit the following for vote at the meeting on Thursday, June 25, at 2 p. m.

" 'The single-wire system with grounded return shall be recommended practice.'

"We believe it inadvisable for the S. A. E. to adopt such a recommendation at this time, and respectfully ask your consideration of the following arguments in favor of postponing action for at least 1 year.

"Advantages of the Grounded Return.

"First, Better contact and insulation in the lamp receptacle.

"Second, Fewer connections and simpler wiring.

"Advantages of the two-wire system.

"First, Not necessary to provide special returns for lamps carried on the body.

"Second, Short-circuit impossible if one ground occurs, or if two occur they must be on opposite sides of the line to form a short-circuit.

"Third, Circuits do not depend on lamps being tightly secured to the lamp brackets.

"Fourth, Circuits do not depend on the cleanliness of the metal frame where the ground is made as on single wire systems.

"Before a standard is adopted it would be advisable for the society to further consider the trend of electrical equipment design.

F. E. Moscovics, of the Marmon company, stated that he wished to warn the S. A. E. against the too rapid adoption of a recommendation, especially one of such a serious nature as this, where such eminent authorities seemed to be divided in their opinions. He cited the case of the Bosch design, where in spite of the fact that in their one-wire system they intended to lay out their design without fuses they were compelled finally to fuse every circuit for safety's sake.

W. H. Conant stated that he regretted that A. L. Riker, the chairman of the division, was not present to throw the weight of his personality and arguments into the matter. He said in part: "This matter has been discussed and postponed now for 2 years. In the meanwhile the car makers are doing

Some of those who took a prominent part in the one and two-wire discussion: Joseph Bijur, Bijur Lighting company; Leonard Kebler, Ward Leonard company; W. H. Conant, Gould Storage Battery company; F. E. Moscovics, Nordyke & Marmon; David Fergusson, Pierce-Arrow; A. L. McMurtry, consulting engineer; R. McA. Lloyd, consulting engineer as they please and adopting rapidly the one-wire system. After consideration of the subject the Electrical division had decided that the adoption of this system would be the starting points of much better electrical practice."

Herbert Towle said: "The question seems to me of two-fold importance. First, the strongest objection to the one-wire system is in its lack of safety. Any ground causes a flash and in the presence of gasoline a flash means a fire. Secondly, a sound, durable condition of insulation must exist. Automobile manufacturers are careless in wiring, etc., and are not giving the electrical equipment a chance to show itself to its best advantage."

Mr. Moscovics stated his opinion that the art had not progressed far enough to settle a question of this nature as yet or to assert that one practice is better than another. Mr. Conant retorted that this argument could have been used at the time of adoption of practically every standard. He stated that Mr. Riker was at one time an advocate of the two-wire system, but was convinced the single-wire was better.

Mr. Moscovics stated that the only difference in Mr. Conant's ideas and his own was that he believed the art had not progressed far enough to adopt the recommendation. R. McA. Lloyd stated that he believed it would be easier now than a year hence. He stated that 60 or 70 per cent. of the cars now being built have the single-wire system. E. H. Ehrman, of the Chicago Screw Co., moved that a vote be taken on the matter, and after Joseph Bijur, of the Bijur Lighting company, had stated himself as being against the adoption of the system, Mr. Lloyd asked him why he had voted for it in committee. Mr. Bijur stated that he had never expressed himself as being in favor of the recommendation, but had merely remained silent after seeing the hopelessness of winning over those who wanted it. He said that the fire risk with the single-wire system was not twice as great but 500 times as great and that he believed the underwriters would stop us if the single-wire system were adopted. Mr. Bijur said: "Motor car manufacturers do not use the single-wire system because they like it better but because it uses less wire."

Albion D. Libby, of the Splitdorf company, cited the case of a $3,500 car which recently had caught fire through a short circuit and on which disaster had been prevented only by a quick removal of a battery lead by an expert who happened to be near. He stated it as his belief that the S. A. E. should not recommend the practice merely because "manufacturers who are turning out cars like sausages are using the single-wire system."

Mr. Conant stated that since there were not many in the room and the hour was getting late the vote be held over. Herbert Towle asked, "Why not hold over another year?" Mr. McMurtry stated that it was his belief that the issue should not be delayed, and cited the fact that the General Electric Co. built their high-voltage cars on the one-wire system. To this Mr. Moscovics rejoined that they were driven by experts.

David Fergusson, chief engineer of the Pierce-Arrow company, said that they had shifted to the one-wire system because of trouble with the two-wire system in getting good lamps and fittings.

A vote was then taken and the motion to pass the recommendation was lost. Mr. Conant protested that fifty voting members were not present.

6-Volt System vs. 12-Volt System

ALBION D. LIBBY'S paper on the new Splitdorf electric lighting, starting and ignition system provoked a debate on the merits of the 12-volt system.

W. H. Conant, of the Gould Storage Battery company, stated that he was in accord with the trend toward the 12-volt system. The reason he assigned to that tendency was the increase in efficiency of the 12-volt motors. He went on to say:

"Mr. Libby mentions the size of the plates, stating that they should be of sufficient size to meet the requirements of power, but I would like to emphasize that cognizance must be taken of the quantity and quality of the electrolyte. I further believe that it is not good practice to put the head and side lamps in series. The headlights have a tendency to flicker and if one is in trouble both go out. Concerning the use of fuses I believe it to be desirable but question if it is practical. Fuses are peculiar things, as I am well aware from knowledge of experiments on fuses which have covered years. It is hard to say, however, what they will do, even if they are only limited as closely as mentioned in the paper. Assuming that we have a fuse and it is blown, it means that the circuit is overtaxed, that something is the matter with the motor which makes it hard to crank. The owner or driver of the car will have to search for the trouble, and he is sure to close his circuit with a pair of pliers or a piece of copper wire or some other means.

"In fact," continued Mr. Conant, "I even suspect that some of you gentlemen have bits of copper in the basements of your houses which are doing the work that fuses should do. I agree with the author of the paper that an ammeter should be used and am convinced that the driver of today takes a delight in informing himself on the mechanical and electrical devices on his car."

Albion D. Libby, patent attorney for the Splitdorf Electrical Co., whose paper on electrical equipment started the discussion on 12 volts versus 6 volts

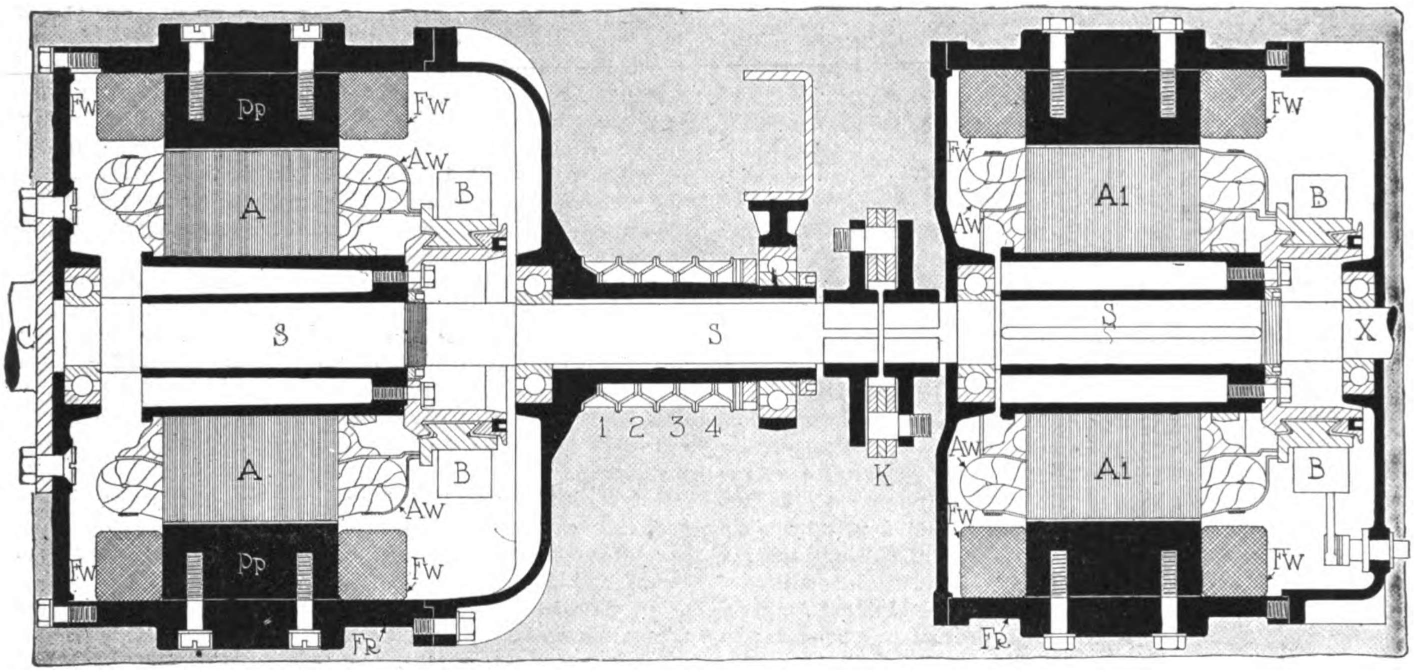
Mr. Libby illustrated the light weight of the present-day starting motor by citing an installation of a 22-pound motor on the Winton car he had driven down to Cape May. He said he wanted the lamp builders to build lamps of higher voltages and that he believed that the 14-volt lamp focussed as well as the 7-volt type.

Mr. Lloyd said he differed with Mr. Libby and favored the 6-volt lamp on account of its better focussing ability and stronger filament. Mr. Moscovics mentioned the latest Bosch 12-volt lamp and illustrated its filament, asserting that it had excellent focal ability. Mr. Libby said he was an optimist on the lamp situation and pointed to the example of the 6-volt lamp which at one time consumed 4 watts to the candlepower but now was rated at 1 watt per candlepower.

Mr. Bijur said that he was not committed beyond reason to the 6-volt system, but that he had seven arguments in its favor. These are as follows:

Less battery weight, stronger filament, only three cells, better focus, stronger portable lamps, less space for insulation, punch of 6-volt motor as good.

Electric Transmissions for Motor Cars



IN the Entz system of electrical transmission, the patents for which are owned by R. M. Owen & Co., New York City, a generator and a motor are used in an unusual way. The casing of the generator FR, which carries the fields or pole pieces PP, is bolted directly to the crankshaft and thus replaces the flywheel; the armatures, A and A1, of the two machines are coupled together at K and their shaft S is permanently fastened to the drive shaft at X at the rear. The fields of the motor are stationary, being supported by the frame.

The speed of the car is regulated by the throttle and the torque for different loads is varied by changing the field strength of the generator and on lower speeds, by sending the generated current to the motor. When the car is running along the level, at which time a mechanically driven car would be on high gear, the generator winding Aw is short-circuited on itself and therefore with a very slight amount of slippage between the field and the armature, a heavy current is generated, this current being of sufficient strength so that the magnetic attraction between field and armature is equal to the torque required to propel the car at that speed. The slippage varies directly with the torque required, so that if a slight grade is encountered, the slippage will become slightly greater; this will increase the voltage of the generator and then the current will increase, which will produce a stronger magnetic attraction for the armature on the field, and thus the torque will become greater. On high gear the slippage might be, for example, 40 revolutions per minute when the engine is making 1,000 revolutions.

On lower speeds, and there are seven, the increase in torque on the drive shaft is obtained by weakening the fields of the generator and also by sending the current generated into the motor. When a very steep hill is encountered, the torque between generator field and armature will be greater than the engine is capable of producing if the field is not weakened or the current pumped into the motor, and thus the engine would slow down. But when the field is weakened, the motor must rotate just so much faster to produce the maximum pulling force between the field and the armature of the generator. This means a large increase in the slippage and thus a large current will be generated and pumped to the motor where it will aid in pulling the car up the hill.

Digest and Discussion of Paper by Justus B. Entz

ELECTRIC transmission systems as applied to motor cars are constituted of methods of electrically controlling the transmission of the power of the engine to the wheels. It is necessary not only to control and transmit the power but to do so at varying speed and torque ratios while developing the full power of the gasoline engine.

One method of electric transmission consists of a dynamo or electric generator driven by the engine and supplying electric energy to one or more motors connected with the driving wheels.

Another method consists of a dynamo-electric machine connected with or mounted on the driving-shaft and adapted to assist the engine at times of heavy load, drawing its energy from a storage battery, and in turn charging at times of light load, becoming automatically a generator for that purpose and utilizing the surplus power of the engine.

Justus B. Entz

The third system is known as the Entz electric transmission and consists of a dynamo-electric machine, one member of which, the field magnet, is connected to the engine crankshaft and takes the place of the flywheel, the armature being connected with the driving-shaft. This unit serves to transmit the turning effort of the engine to the driving-shaft by means of current established in its circuit, due to a speed difference between its members on what constitutes the high speed of the electric transmission.

This clutch-generator of the electric transmission constitutes a very elastic clutching and transmitting means, but is not by itself capable of transmitting more than the torque of the engine. For higher torque upon the driving-shaft, use is made of an electric motor whose armature is mounted upon the driving-shaft and which receives current from the first machine or clutch-generator. Thus on speed positions below the highest the motor is included in the circuit of the clutch-generator. If the windings of the two machines be the same, and the same current passing through each, the torque represented by that current which will be the same in each, and the electromotive-force will be the same in each for the same speed-difference between armature and field.

Thus if the full torque of the engine were transmitted for a slip or speed-difference between armature and field of the clutch-generator of 75 revolutions per minute and the motor with the same electrical resistance were included in the circuit, the slip loss would be increased to 150; if the engine were running at 1500 revolutions per minute the speed representing useful power would be 1350 revolutions per minute at engine torque; but the torque on the driving-shaft will have been doubled because of the motor, and a C.E.M.F. all will have been set up in the motor, which must be overcome by the clutch-generator, which results in a speed of 675 of the driving-shaft and a torque double that of the engine, the clutch-generator then having a slip of 825, 150 being due to the resistance of the clutch-generator and motor and 675 to overcoming the C.E.M.F. of the motor, the latter representing useful work in the return it gives to the driving-shaft in additional torque. Gradations of control in speed and torque are secured by means of varying the field strength of the clutch-generator and motor, as will be shown later on.

We will now consider the electric transmission of the engine power to the wheels and make a comparison between a generator-motor system, wherein the generator converts all of the power of the engine into electric energy and supplies it to the motor, and the Entz electric transmission system wherein the generator acts also as a clutch and converts only part of the engine power into electric energy, and only when in the lower speeds.

Inspecting Owen car with Entz transmission. From left to right, C. W. Hatch, R. M. Owen, J. B. Entz, H. C. Wilson

The electric energy equal to the maximum horsepower of 42 1-2 at 1,500 revolutions per minute is 31,700 watts. We will consider that the same electrical units are used in each of the two above-mentioned systems. We will call the current which represents the full output of the generator at full field strength 100 per cent. We will call the C^2R loss at this current 2 1-2 per cent. of the total input, for each armature and each field winding, and the core losses for full field strength and full speed difference 5 per cent. in each armature. The first losses vary as the square of the current and the core losses nearly as the square of the voltage, or the product of the field strength and speed, to which the voltage is equal.

In the generator-motor system with 100 per cent. current we have 2 1-2 per cent. C^2R loss in each armature and field winding or 5 per cent. in generator and 5 per cent. in motor, a total of 10 per cent., which appears as a speed loss as it lowers the effective voltage by that amount, so that the vehicle speed is reduced from 50 miles per hour, corresponding to 1,500 revolutions per minute of the engine, to 45 miles per hour. There is also 5 per cent. core loss in each armature or 10 per cent. total, corresponding to a reduction in tractive effort from 6.9 to 6.2 per cent. The total efficiency is 80 per cent.

Full Torque Transmitted

In the electric transmission system the full torque of the engine is transmitted by the generator unit alone, short-circuited upon itself, and with no torque loss.

To get double the torque with the electric transmission it is not necessary to increase the current, but the motor is included in the circuit of the clutch-generator and its torque added to that of the engine as transmitted by the clutch-generator and the latter slips a little more than one-half engine-speed to supply the necessary voltage for the motor.

To get three times torque with the generator-motor system we will figure on 300 per cent. current and 3 1-2 times torque of 100 per cent. current.

To get three times torque with electric transmission we must double the current through the motor and reduce the field strength of the clutch-generator to one-half so that it can deliver double current.

Herbert Chase Opens Discussion

Herbert Chase opened the discussion on this paper by asking if the curves shown were founded on practice. To this Mr. Entz replied that the curves were the results of dynamometer tests. He further stated that with this system the gear reductions do not vary and that in slipping the clutch you secured the same effect as with the ordinary type of drive. A. L. Moscovics, of the Marmon company, asked if Mr. Entz had any data on the amount of weight saved by the use of the electric transmission. Mr. Entz replied that so many of the parts of the car were replaced that there was no resulting weight increase of importance. Mr. Chase asked if the weight could not be further reduced by the use of a light-weight high-speed motor. Mr. Entz stated that he thought this would be feasible by using a greater reduction in the transmission and also that it must be remembered that the weight of the electric starter is included in the plant.

R. McA. Lloyd, a consulting engineer of New York, stated that in his belief people were not satisfied with merely the transmission of torque, but that they want an actual transmission of horsepower. That is to say, they want the capacity to get the power to the wheels, and while it is comparatively simple to get torque a large motor generator is necessary in getting power. He said, also, that it is impossible to state that there is no loss of power through the transmission. Mr. Entz agreed with him, saying that it is not true that there is no loss in the transmission, but that

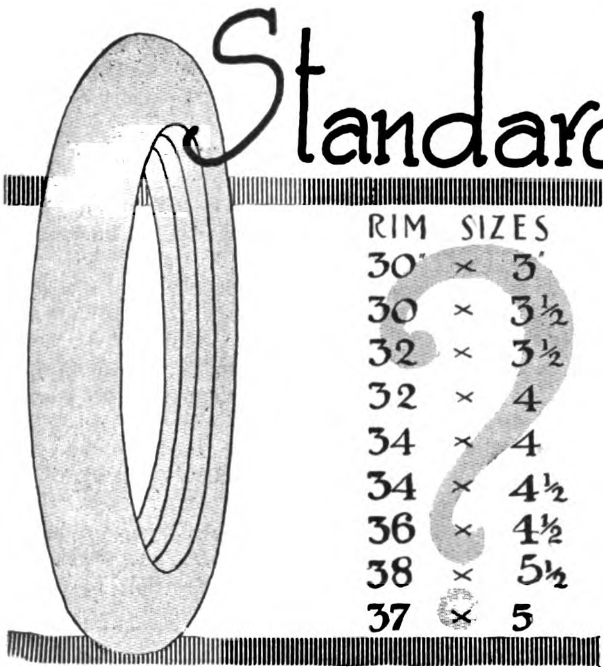
Standardizing Tire Sizes



Society Aims to Reduce Tire Sizes from Fifty to Nine—Important Papers and Discussions—Rim Test Determined

THE tire work of the Society was divided under two heads, standardization and educational. The standards work was incorporated in the reports of the Pleasure Car Wheels division and the educational work in papers presented by E. R. Hall, C. C. Carlton and J. E. Hale.

When brought before the Society, the report of the Pleasure Car Wheels division was offered by its chairman, Henry Souther, as a progress report with the exception of that part which refers to the method of rim inspection, this being in such from that approval was thought advisable. The only other subdivision is that offering eight sizes of tires as recommended sizes. These eight sizes will take in 85 per cent. of the demand, the oversizes comprising a good part of the remaining 15 per cent.

The main features of this report follow:

James E. Hale, Experimental Engineer of the Goodyear Tire & Rubber Co., who is actively interested in tire standardization

Routine Test of Rims

It is the opinion of the Pleasure Car Wheels division that the test of bursting strength or to destruction is not the best routine test to be used in connection with the inspection of rims for pneumatic tires. It is the opinion of the division that a pressure test with predetermined deflection under predetermined pressure is a good routine test; the test to be made with water pressure.

The measurement of deflection of a clincher rim should be made across the outside of the clinches.

The deflection of a straight-side rim should be measured across the edges of the straight sides.

Tire Sizes Determined

In recommending a decreased number of tire sizes the division considered the needs of the different weights of cars and fixed upon a sufficient number to take care of the weights of the entire range of cars and at the same time permit the engineer sufficient choice to allow him to provide a satisfactory factor in taking care of different car loads.

Eight tire sizes which the division decided to recommend are shown in the following table:

RIM SIZES	TIRE SIZES					TIRE SEAT DIAMETER
30x3	30x3					24"
30x3½		30x3½				23"
32x3½		32x3½				25"
32x4			32x4			24"
34x4			34x4			26"
34x4½				34x4½		25"
36x4½				36x4½		27"
38x5½					38x5½	27"

This table, it will be noted, involves only eight rim sizes, and five tire seat diameters. One or two other regular tire sizes are under consideration by the division.

It was thought by the division that tire oversizes should not be recommended for regular equipment.

In speaking of the report, Mr. Souther pointed out that the deflections given are the results of a great many tests, and that no attempt at enforcement of the recommendations would be made before next January, in order to give the manufacturers time to prepare for them. Standard demountable rims are not ready for report, the division feeling that it needs more light on the subject and more investigation before anything concrete is offered the Society.

A good point was made by O. A. Parker when he said that the standard rims would be economical to maker and user alike to utilize well-balanced tires. If they are too large in section, they are out of proportion and hence not serviceable.

Fergusson Wants 37 by 5 Standard

David Fergusson thought that the 37 by 5 size should be added to the list of standard sizes. It is now regarded as an oversize, but it is used by a large number and has been found to be a very good proportion.

E. R. Hall explained that it was the intent to have all the tire sizes even, and that the standardization should cause all manufacturers to use even sizes, whereas the manufacturer who puts a 37 by 5 on a 36 by 4 1-2 rim gives no chance for the oversize idea, except that the purchaser would then regard the 38 by 5 1-2 as the oversize. This is somewhat out of balance, however.

Henry Hess has run a car equipped with 37 by 5 tires for months on the original air and finds that size very useful, strengthening Mr. Fergusson's remarks. He made the point that by having oversizes, the report suggests that the user pay extra, and he could not see the reason for having a well-proportioned size such as this 37 by 5 made anything but standard.

Mr. Souther agreed that this extra charge point was logical, but pointed out that no matter what size tires are on the car, some customers always want something a little larger. If the car be equipped with 37 by 5 tires, some would want 38 by 5 1-2 sizes.

Mr. Fergusson objected to the 36 by 5 as being a size which is not known, but Mr. Hall stated that this size has had considerable testing and is found to be better than the 36 by 4 1-2 or the 37 by 5, due to better balance that may be thus secured.

E. R. Hall, Experimental Engineer of the Goodyear company, who is active in tire standardization

Mr. Souther said the division was glad to get the suggestions, and explained that even if several more sizes had to be added to the eight proposed as standard, it would not be a serious matter. There are at present from 48 to 51 sizes which have to be furnished by the tire people, and the drop to eight or ten is a big one indeed. He deprecated the unfortunate use of very large oversize tires on narrow rims, likening this practice to the big soap bubble which wobbles on a pipe. It is the same with the big section tire which rolls on the narrow rim against the side rings and tends to rim cutting and flexing of the bead.

Three Educational Tire Papers

Three papers, which will prove of great assistance to the Pleasure Car Wheels division, were given the society at this meeting, occupying a good share of one of the morning sessions. These dealt with the standardization of rims and felloe bands and were the results of exhaustive research and experimental work by E. R. Hall, experimental engineer with the Goodyear Tire and Rubber Co., and C. C. Carlton of the Firestone Tire and Rubber Co. Two of these papers were by Mr. Hall, one being a criticism of the standard rims adopted by the Society of Motor Manufacturers and Traders of Great Britain, and the other dealing with suggestions for the standardization of pneumatic tire rims. Mr. Carlton discussed the possibilities and difficulties of formulating acceptable recommendations for one standard felloe band for wheels to be equipped with pneumatic tires.

The British Standardized millimeter clincher rim was decided upon in June, 1913, and tolerances were adopted in September, 1913. These are open to criticism from the American viewpoint, and Mr. Hall explained why. The main features of this paper follow:

Ever since the clincher type automobile rim has become popular in Great Britain and Europe a chaotic condition has existed in millimeter rim design. Each manufacturer of millimeter rims had his own so-called standard design to which he worked and the result was that rims marked the same size and supposed to take the same tire differed widely in design. The tolerances which the rim manufacturers allowed themselves were so gross that there was oftentimes considerable variation between two rims of the same size and manufactured by the same manufacturer. This condition prevailed in spite of the fact that it is ruinous to a beaded edge or clincher type tire, such as is in general use abroad, to be used on a rim which it does not fit exactly. A great hardship was thereby worked upon the tire manufacturers who had to make the bead of their tire small enough to slide into the smallest rim of its rated size on the market, and to trust to luck for satisfaction in their product when used on the larger rims of its rated size.

The Society of Motor Manufacturers and Traders of Great Britain in June, 1913, standardized the millimeter clincher rim and later, in September, 1913, adopted a set of permissible tolerances to which the rim manufacturer should work. The society has produced a most complete set of rim checking templates, tapes and printed specifications covering its standard.

As far as we are able to determine, this standard, known as the S. M. M. T. standard, has been universally adopted abroad.

Although a very great step in the right direction and possibly the best that could be made at this time, the S. M. M. T. standard is open to criticism from the American viewpoint.

Two Chief Dimensions

It will be noted that the two chief dimensions of the rim section are the width between clinches and the depth of clinch and that the majority of the other section dimensions can be expressed in terms of these two. As a matter of convenience and record this feature is admirable. The width of the rim was apparently chosen arbitrarily, as it does not increase in increments corresponding to the increase in rated rim size. Between any two of the first six sections the increase in rated size of rim and tire section is exactly 15 millimeters, while the corresponding increases in width are respectively as follows: 13.0, 11.0, 5.0, 9.5 and 13.5 millimeters. The increase in rated size between the 150 and 175-millimeter rim is 25 millimeters, while there is no increase in width. We would have preferred to have this increase a constant quantity, possibly 10 millimeters, between any two consecutive sizes from 75 millimeters to 150 millimeters, inclusive, and the increase between the 150 millimeter and 175 millimeter sizes to be the same as at present. This would certainly give a more uniform and logical step-up in tire sectional

Group of those who entered tire discussion: Left to right, E. R. Hall, Cornelius T. Myers, mechanical engineer; W. H. Roberts, assistant engineer of the department of finance, New York City, and James E. Hale sizes, provided the tires were made anywhere near rated size.

The depth of clinch increases by very small increments as the rim size increases, not more than 2 millimeters in any case. As these differences are so small, and in view of the fact that the tolerances prescribed permit them to entirely disappear and in some cases overlap (as will be noted below), we would prefer to see dimension *V* equal 13 millimeters for both 90- and 105-millimeter rims and 16 millimeters for 120- and 135-millimeter rims. This would give only four different inside rim contours instead of six as at present prescribed, making it necessary for the rim manufacturer to have only four sets of contour rolls instead of six, thus cutting down the forming roll equipment 33 per cent. Under these conditions the rims should fit the tires exactly as satisfactorily as in the case of the present standard.

The American Viewpoint

The above criticisms and suggestions are entirely from the American viewpoint. We must admit that the S. M. M. T. standard as it stands is a very great improvement over former conditions, and is probably the very best that could be attained under the circumstances. Credit is due the Society of Motor Manufacturers and Traders for causing the adoption of an admirable rim section contour comprising excellent proportions, bearing the same relation to each other in all sizes. In this particular their standard is certainly better than the American standard.

It is improbable that any of the improvements to the S. M. M. T. standard suggested above could be incorporated at this time. For this reason we favor its universal adoption in its present form, excepting tolerances.

The tolerances specified by the S. M. M. T. standard are so great that they almost entirely defeat its purpose from the American standpoint. Accustomed to rims manufactured with a very high degree of precision and to very close tolerances, the American tire manufacturer designs his tire to give an ideal fit on a rim exact to standard and he is sure the tire will fit practically as perfectly in a maximum or minimum rim of its size. If a tire is made to fit a correct S. M. M. T. standard rim as perfectly, the tire cannot be made to enter a minimum rim and will float around and be a very poor fit in a maximum rim.

Very helpful data and valuable suggested standard rims for pneumatic tires are given in Mr. Hall's other paper. There are six representative groups of rims manufactured today, and from each a typical rim, which combines all the attractive and as few of the unattractive features of the rims of its group as possible, is picked out. This applies to all except the demountable rims, in which case only the selection of the felloe bands was made, leaving the type of top rim optional.

C. C. Carlton in his paper on standard pneumatic felloe band recommendations pointed out that there is no part of the motor car in which there are more varieties and at the same time more possibility of standardization. He makes plain the feasibility of standardization of the wood felloes for the three types of rims, namely, the demountable, detachable and the clincher. His remarks follow:

The Pleasure Car Wheels division of the Standards Committee, of the Society of Automobile Engineers, was created to study various types of pleasure car wheels with particular attention to diameters, to various types of steel felloe bands and to the various methods of carrying pneumatic tires thereon. From this standpoint, pleasure car wheels can be divided into three classes, namely, those equipped with a one-piece regular clincher rim; second, those equipped with quick detachable rims requiring no steel felloe, and third, those equipped with a steel felloe band upon which is mounted a demountable rim.

We believe we are safe in saying that there is no part of the automobile in which there is more variation and at the same time, in which there is so great a possibilitiy of standardization as the wheel. The types of tire carrying rims being manufactured number about fifty, while the types in general use actually run over twenty.

One-Piece Regular Clincher Rim

The most simple form of an automobile wheel is the first above mentioned, namely, that carrying a regular clincher rim. The rim is practically standardized at the present time, the only variation possible being in the thickness of the steel from which the rim is manufactured. This variation is so slight that for all practical purposes the wood wheel may be considered already standardized.

Quick Detachable Rims

The quick detachable rim, whether for clincher or straight side tires, varies only in the thickness of the steel itself, and in the method for detaching the tire. For all practical purposes it may be said that the wood wheel on which quick detachable rims are used, is already standardized, the only variation now being the thickness of the steel section. The only further step that can be made in the standardization of the wheel carrying a quick detachable rim is to standardize the device for detaching the tire, and there are so many greater problems presenting themselves, that it seems well to forego any further action along this line, for the present at least, especially in view of the fact that the quick detachable rim has been practically displaced by the demountable.

Two Distinct Classes of Demountable Rims

As already said, the consideration of the adoption of a standard wood wheel dimension for all demountable rims, presents at once the type of steel felloe, which in turn is governed, first by the device by which the tire carrying rim is fastened, and second, by the very nature of the rim base itself. Practically all of the demountable rims in common use, in fact, considerably over 90 per cent. of the demountable rims purchased by the car manufacturers today, can be divided into two classes: First, the so-called local wedge type rim which is seated upon a felloe band manufactured from straight bar steel, by merely being flanged up in some form at the back side; the bearing at the front being secured by a type of local wedge which is forced flat against the steel felloe on the one side and upon which the tire carrying rim rests on the other.

The second class of rim above mentioned is equipped with two beads on the underside of the rim base. The rim in this class are for the most part quick detachable as well as demountable. The felloe band itself must be a hot rolled section with a flange or bevel upon the back side upon which the bead of the rim rests. Whether this rim be for straight side, clincher tires or universal, is immaterial as far as the present discussion is concerned.

This type of rim depends for its fastening device either upon a continuous wedging ring or upon a local wedge which has a similar bearing. This type is in use by a very great majority of American cars selling at $1,500 or above.

The members of the Pleasure Car Wheels division, who have spent much time at the study of this problem, will admit, we believe, that it will be a comparatively simple matter to adopt a set of wheel dimensions and a set of steel felloe bands, to which could be adapted with only slight changes, considerably more than 90 per cent. of all the rims of this type in common use. This would be a step forward, but to have adopted two S. A. E. standard truck felloe bands, we will all admit now would have been a mistake.

Universal Standard—The Acme

Mr. Wall, in opening the discussion, agreed with Mr. Hall that the Acme is some day to have a universal standard for rims. The time will come when we will be as interested in this work as we are at present in the American standards.

Mr. Carlton agreed with everything Mr. Hall said and suggested writing to the S. M. M. T., telling that organization of the objections of the Americans to these low tolerances.

Mr. Hall pointed out that he has advocated two types of felloes in his paper, while Mr. Carlton seeks to standardize one alone. This, of course, is very desirable, but Mr. Hall thinks it almost too much of an undertaking to come at once, two being hard enough to consider.

Further backing up his argument against the introduction of a 36 by 5 tire, Mr. Fergusson explained that it means another size of felloe band, whereas the 37 by 5, the 36 by 4 1-2 and the 38 by 5 1-2 take the same band—additional support for the 37 by 5.

Truck Tire Situation an Important Element

Easily a feature of the meeting was the paper by J. E. Hale of the Goodyear company, entitled "A General Summary of the Truck Tire Situation." This gives a synopsis of the whole solid tire matter and shows that the situation is really quite complex. The paper is one of the best expositions of the condition of affairs which has been compiled and indicates a great deal of research work by its author.

The question is largely a matter of how best to compromise between the hard tire and the more resilient type. The very hard rubber tire is longer lived, but, on the other hand, it gives the mechanism of the truck more vibration, whereas the softer type which is best in this latter respect has a shorter life. The great need is for a better interchange of compositions among the tire people and the giving by the manufacturers of better tires in the opinion of truck men.

The Hale paper, which appeared in the May Bulletin of the society, is given in part:

The Truck Standards division in its efforts to arrive at a universal schedule of solid tire carrying capacities satisfactory to all concerned, discovered that the situation is really quite complex and decided therefore that a synopsis of the solid tire situation as a whole might be worth while. As an introduction let me state that there is almost no opportunity to resort to theories and exact formulae in solid tire design, a fact which will be readily appreciated after consideration of the discussion which follows; experience and judgment being by far the chief requisites for producing results. It is fair to add, however, that the application of good engineering practice and methods can reasonably by expected to produce better results than could be obtained from the hit-or-miss attention of salesmen and factory workmen. It is unfortunate that the art has not progressed sufficiently to permit the presentation of data and facts which can be considered at all complete or satisfying. However, even though the absence of theories and data is so regrettable I hope, since the truck tire problem is so intimately connected with the truck industry, to find that the following remarks will prove of interest, and especially that they may serve as a basis of starting something for the betterment of the situation.

Taken in a broad sense undoubtedly economy of truck operation is the real issue. It follows therefore that if an "economical tire" could be evolved an ideal solution would be at hand.

Solid tires in service under certain operating conditions give certain results in the performance of their functions. These results are dependent on the tires themselves and on the conditions under which the tires are used.

Mr. Hale stated that there is no doubt that a large proportion of the energy of the motor is consumed in internal friction in the tire itself and that it therefore follows that there would be a saving in gasoline if there were not so much energy consumed in the tire. These conclusions are founded upon experiments.

Electric Transmissions for Motor Cars

(*Continued from page* 9)

at high speed the loss does not exceed 5 per cent. of the power of the engine. Because the torque is transmitted directly there is but small loss. The principle is the same as in the electric dynamometer, the difference in speed between the two members of the dynanometer causing the only loss.

Mr. Lloyd inquired if there was no loss of energy in keeping the magnets excited. To this Mr. Entz exclaimed: "Yes, that is where the loss occurs because that means the difference in speed between the dynamometer elements." He further stated that there is also a core loss and an eddy current loss as shown in the tabulations given in the paper. In response to question as to external resistance used in control Mr. Entz replied that this was only used in employing the dynamometer as a brake. The shunts to the motor field are not external, being contained within the controller unit. He stated his belief that as a manufacturing proposition the electric transmission would be cheaper than the mechanical, because the testing and assembly work are much simplified. The circuit is always closed.

Can Run Steadily at Full Load

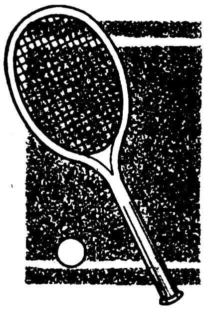
John Heinze, chief engineer of the Northway Motor Co., asked how long the electric transmission would last if it were run continuously at full load. To this Mr. Entz replied that it would be forever. To Mr. Heinze's inquiry as to the rise in temperature, Mr. Entz stated that the apparatus would never become so warm that the hand could not be placed on the brushes or coils. He further stated that when run as a clutch there are no core losses at all. As first constructed the armature shaft was non-continuous, but now it is manufactured in one piece.

Mr. Heinze asked what would happen if a 50-horsepower machine were taken to the Indianapolis speedway to be run at high speed; what would the weight of the magnetic parts be. Mr. Entz stated that the armatures would weigh 100 pounds each. Mr. Heinze expressed his conviction that with the transmission of so much power through such small units there must be a marked temperature rise, but Mr. Entz said that as far as the temperature was concerned the plant would stand the full horsepower. Bruce Ford, of the Electric Storage Battery company, Philadelphia, asked if the power would be proportional to the slip in the 50-horsepower engine. Mr. Entz replied that the full torque of the instrument is transmitted to the rear wheels and to a further inquiry from Mr. Heinze Mr. Entz stated that if the motor developed 50 horsepower then 48.5 would be delivered to the propeller shaft.

High Efficiency Obtained

Mr. Entz stated that the elimination of the losses in the instrument permits one to work at high efficiency with a wide open throttle, and that in ordinary work it is similar to any clutch where it can be worked at a slip and still transmit torque to the rear wheels. Mr. Heinze then stated his belief that in all ordinary work the electric transmission is perfectly satisfactory.

A general debate ensued for a time on the possibilities of transmitting such a large amount of power through such a comparatively small and light unit. To clarify the situation, Herbert Towle explained that it must be remembered that the generator developed only 5 per cent. of the energy imparted by the transmission and therefore for transmitting 50 horsepower it need only be a 2.5 horsepower electric machine. The only time that the machine will have to get rid of any amount of heat would be when the field lags behind the armature and therefore the heat is least when the slip is a minimum.



All Work and No Play Makes Jack a Dull Boy

ON Friday afternoon, on the sands where America's first Beach Races were held, after the business of the meeting had ceased to occupy the attention of the engineers, they turned themselves loose on the program of sports that had been arranged by Chairman F. E. Moscovics, of the Marmon company, who headed the sports committee. After the grand parade, in which was incorporated a contest for the most bizarre costume, the cortege broke up and assembled on the hard beach. Here, amid the clicking of moving picture machines and the snapping of camera shutters, the engineers disported themselves with a remarkable lack of dignity.

Conant Takes the Prize

Coker Clarkson, general manager of the S. A. E., in a modest baby blue Oliver Twist suit, gamboled about the beach without fear, surrounded on all sides by the tribe of Indiana section Indians in full war paint. But, best of all, was ballet dancer W. H. Conant, the erstwhile silver-tongued orator for the single-wire system in the warmest debate of the professional session. Dressed in a delicate pink lampshade ballet costume, with a mass of much-bleached blonde hair, he easily captured first honors.

In the baseball game, which was of the indoor variety, the Indians literally tied their Metropolitan rivals to the stake. The tenderfeet had no show, in spite of their brilliant playing, for, wherever the ball was batted, the huge form of an Indian in full war paint would loom up and with the easy grace of months of preparation for this contest, would put the Metropolitanite out. The final score was 12 for the Indians and 5 for the Metropolitans. The batteries for the winners were Berne Nadall, advisory engineer of the Stewart-Warner company, and E. L. Vail, of the Waltham Watch Company. For the Metropolitan section the twirling was done by Herbert Chase, laboratory engineer of the A. C. A., and the catching by D. J. Burns, of the Ward Leonard company.

Finish of the 100-yard dash by J. Edward Schipper, winner of the S.A.E. all-around athletic championship.

Waltham Watches for Athletics

The field contests were next held, the matches including a base running contest, shot put, hammer throw, 100-yard dash and a swimming race. The scoring was done on a point system, in which first place counted 5, second 3 and third 1. The contestant securing the greatest number of points was awarded the all-around championship trophy, a beautiful opera model gold watch donated by the Waltham Watch Company. Separate trophies were awarded for the base-running contest, and the aquatic championship, although points on these contests were included in the all-around championship. The tennis tournament, bowling and fat men's race were not counted in the all-around championship, but had trophies of their own. Alfred Reeves, general manager of the National Automobile Chamber of Commerce; John Wetmore, of *The Evening Mail*, and George W. Houk, of the Houk Mfg. Co., were in charge of the scoring.

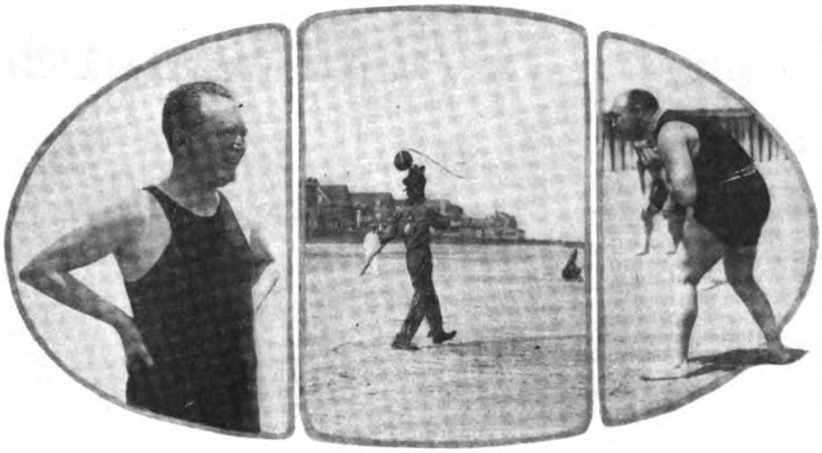
The all-around athletic championship of the society was won by J. Edward Schipper, Engineering Editor of THE AUTOMOBILE, with thirteen points acquired by first place in the shot-putting and broad-jumping events, and second place in the base running. Second place was taken by S. L. Murfey, of the Grant Lees Gear company, a new applicant to the society, with 11 points gained by taking first place in the swimming and base-running matches and third in the 100-yard dash.

The 100-yard dash was won by D. R. Swinton, mechanical engineer for the Tuthill Spring company, of Chicago. In addition to capturing first place in the fat men's race, Frank Martin won the hammer throw.

A trophy cup was awarded to Mason P. Rumney, factory manager of the Detroit Steel Products company, and Miss Marion Bate, daughter of John Bate, of the Mitchell company, as first prize in the dancing contest. Second prize in dancing was awarded to Walter Allen, of the Bijur com-

Left—S. L. Murfey, winner of the swimming race and base running contest. Center—D. R. Swinton, winner of the 100-yard dash. Right—Frank Martin, winner of the fat men's race and hammer throw pany, who danced with Miss Margaret Houk, daughter of George Houk, of the Houk Wire Wheel company. The bridge whist prize, a piece of tapestry, was won by Mrs. A. B. Browne, wife of Arthur B. Browne, consulting engineer, Branford, Ct.

The tennis tournament has not as yet been concluded. Herbert Chase has reached the finals by defeating Coker Clarkson. David Beecroft, Walter M. Nones, general manager of the Norma company, and J. E. Schipper are still in the tri-finals. As these men are all from New York, the match will be played off in that city.



Left—William Gray, an active participant in the beach sports. Center—One of the Indians throwing the hammer. Right—F. E. Moscovics, chairman of the Sports Committee

The bowling trophy, a cup offered by the management of the Cape May hotel for the bowler making the highest score, went to R. H. Combs, engineer of the Prest-O-Lite company, who averaged 196 for six games, with 213 as his high score. P. D. Burns, of the Ward Leonard Electric Co., fought him to the finish, having a high score of 206.

Histrionic Ability of Engineers

On Wednesday evening an entertainment program was provided by each of the three sections of the society. The Metropolitan (New York) section gave a mock trial, the Detroit section a paper on the ideal car and the Indiana (Indianapolis) section a trial at the stake by the Indians.

In the show given by the Metropolitan section the plot was a mock trial of the driver of a cyclecar who, while in a hilarious condition, had run between the wheels of a 5-ton brewery truck and wedged the shaft and done other serious damage to it. In the lap of the driver was a young cabaret singer who introduced valuable testimony in the case. The part of the singer was admirably rendered by Herbert Chase, who labored under the name of Miss Cyclecine Bloomerstripe. Others taking part were Joseph Anglada, as Judge Rumhauser; Orrel A. Parker, counsel for plaintiff; J. E. Schipper, counsel for defense; A. E. Potter, court officer; A. J. Poole, truck owner; Coker Clarkson, truck driver; Louis Marburg, fixed post cop; Frank Trabold, motorcycle policeman; A. B. Browne, garage mechanic; N. B. Pope, pedestrian; Henry C. Wilson, Professor S. A. E.; A. B. Cumner, foreman of jury, and eleven jurors.

The Ultra Ideal Car

A paper on the ultra ideal car in which the motor, to conform with the specifications, would have had to be a human being, was read as the contribution of the Detroit section of the society. The car was then driven upon the platform and was shown to be a member of the Detroit section, walking within a baby carriage made up to resemble an automobile.

The Indiana Indians, under the leaderchief of F. E. Moscovics, captured John Wilkinson of the Franklin company and put him on trial for making an air-cooled car. After a trial in which he had practically no chance of defending himself, Mr. Wilkinson was sentenced to spend a week in Tarrytown with John D.

C. C. Hinkley, designing engineer of the Chalmers company, was also captured by the Indians and after a brief trial was sentenced to take Henry Ford riding in a Saxon car and to make him like it.

On Thursday evening the management of the hotel tendered a banquet to the society and this was attended by all the members of the party including, as an innovation, the ladies. The banquet was an informal one and no speeches were made at its conclusion except a toast to A. B. Cumner.

After the banquet the party adjourned to the ball room where Orrel A. Parker, president of the Newmastic company, delivered a lecture on the coming European trip which will be made by the S. A. E. in October. The lecture was illustrated by stereopticon views and motion pictures and proved of great interest.

Mr. and Mrs. R. H. Combs

COMBINING business with pleasure is an art that does not seem to have escaped the members of the society if the social end of the 1914 Summer convention can be taken as a criterion. The fact that many of the engineers brought with them their wives and families added the final touch necessary to make the convention a complete success. Those who left their families behind will probably think twice before doing so again and as time goes on it is safe to predict that this annual outing will be looked forward to as eagerly by the ladies as by the men who derive the benefits of the society and yet enjoy the needed amount of relaxation.

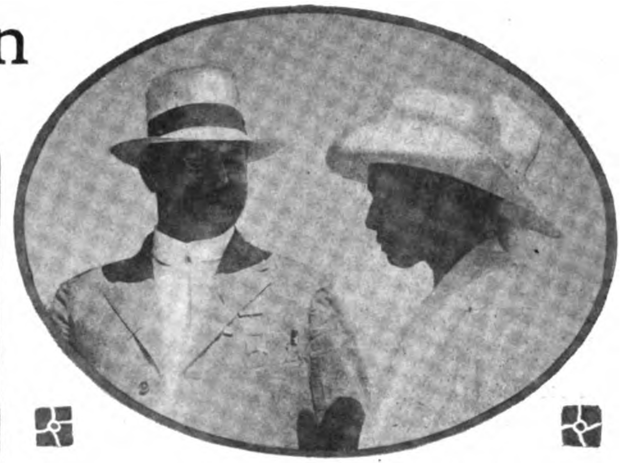
Ladies at the Banquet

A feature this year which was new to the society was the presence of the ladies of the party at the semi-annual banquet. This is a custom which might well grow, as it affords the one opportunity of the year for the entire party to come together. The annual January banquet is generally more of a business occasion, coming as it does in the Winter season when the opportunities for relaxation are not nearly so great and when most of the members of the society are in New York for business in connection with the show.

The annual convention of the society offers to many an opportunity to enjoy the only vacation of which they can avail themselves and at the same time they can hear or participate in the discussions. The fact that the business taken up by the society at these meetings represents to a large extent the latest development of the industry

Delightful Social Occasion

Mr. and Mrs. C. E. Clement taking advantage of the cool hotel veranda



Mr. and Mrs. Ernest E. Sweet

Mr. and Mrs. Alfred Reeves, Miss Margaret Houk and Mrs. David Beecroft

Mrs. David Fergusson

Walter Baker, President, American Ball Bearing Co.

F. S. Slocum, Jones & Laughlin Steel Co., and Samuel G. Stafford, Vulcan Crucible Steel Co.

makes it imperative that others be present and the opportunity of hearing these developments and at the same time enjoying a short vacation has not failed to be appreciated.

Plenty of Recreation

At Cape May the opportunities of the ladies to enjoy themselves was perhaps greater than it has been in previous meetings. On board the steamships chartered for the past two seasons they were limited in their choice of amusements, but at the seashore they had the attractions of tennis, bathing, automobiling, golf, rambling, dancing in such a varied measure that not a dull moment was experienced. The ladies enjoyed the program of sports to the utmost and were equally well entertained by the plays arranged by the Metropolitan (New York), Indiana (Indianapolis) and Detroit sections of the society.

The weather was pleasant during the entire 4 days and full advantage was taken of the spacious verandas of the hotel. The comfortable porch chairs were always occupied by chatting groups of ladies and these were often joined by the engineers and associate members who were for the time being relieved from the duties of the convention. The surf bathing claimed many devotees. The beach is known as one of the best and firmest on the Atlantic coast and is the place where America's first beach races were held.

Trip by Car Fine

The roads to and from Cape May are among the finest in the East. Several who attended the convention traveled in their cars and found a most enjoyable trip through a picturesque part of New Jersey awaiting them. Those who traveled down from New York found convenient stopping places at Lakewood or Atlantic City with the roads in excellent condition all the way to their destination.

Lost

TOO many automobile and parts manufacturing companies are not yet awake to the possibilities accruing from attendance at the mid-winter and mid-summer meetings of the Society of Automobile Engineers.

Those who were unfortunate enough not to be able to attend the mid-summer session last week missed an opportunity to hear at first hand lengthy discussions and pertinent papers on subjects which are of prime importance in automobile development to-day.

Those who consider that there is little to be gained from these sessions are neglecting the opportunity of keeping their ears close to the ground to interpret the more or less vague rumblings from which the story of the future must be deciphered.

On a Tangent

Last week's session was not the best attended for summer sessions, largely due to the fact that Cape May, N. J., is too remote from Detroit, Toledo, Indianapolis and Cleveland to permit of heads of many factory departments attending, who generally attend at their own expense being given the necessary time off by the factory. The session naturally suffered because of the absence of such, and this fact will without question be a strong weapon to have next year's session held on the great lakes or in that immediate locality, where it is a short railroad trip from any of the great manufacturing centers.

That the standards committee with its various active sub-committees is still doing valiant service for the automobile industry was once more indicated by the half-day session that this committee gave over to the consideration of the various sub-standard reports before representing them to the council of the S. A. E. and finally to the entire S. A. E. membership as represented at the meeting in open session.

If any criticisms could at one time be pointed towards this committee for over-zealousness in standardizing automobile parts, there is not any place for such criticism, in fact, the industry is to-day requesting that this committee take up actively other aspects of standardizing and push it to completion as rapidly as possible.

The Pigmy Engineer

At last has a fraction of the industry at least come to realize that the work of standardization is a real work, and that it is now high time to call a halt on those engineers who are using parts that vary but very slightly from standard parts, the only reason for such variation being to have something a little different from the other maker. Such insignificant variations are not engineering but mere whims of the egotist, who is following such a nonsensical policy either to carry out a few of his pet whims or is doing it to impress his organization with his importance as an engineer. In ninety-nine cases out of every hundred it is questionable if any rational excuse can be had for such minute variations.

From 247 to 47

The session brought out one or two, perhaps more, glaring needs for further standardization work, and in each case, it is money back of the movement. The lack of standardization makes the parts cost more to the manufacturer and naturally more to the consumer. Standardization will partly eliminate these abuses. No better example of that could be cited than in the case of tapered roller bearings, as cited in the standards committee work. There are at present approximately 247 different sizes of these bearings and the sub-committee on this work has recommended that this be cut to forty-seven. Some of the roller bearing makers have said that they would desire nothing better than cutting the number from 247 to forty-seven and that the 247 different sizes have been made necessary by the demands of automobile engineers, who have demanded different sizes from those used in similar places by other makers.

In Dollars and Cents

And what do these different sizes cost?

One maker places the factory cost of carrying each size at $8,000.

You can readily calculate the difference to the maker in carrying 247 different sizes at $8,000 each and carrying but forty-seven at the same figure each.

Here is one example of the need of more standardization, and but one of the many examples why engineers from all factories should be present at the regular sessions of the society. The 247 different sizes have been borne by the automobile engineers and not by the bearing makers, and the quickest and surest ways of cutting down to forty-seven is to have these same engineers present and listen to the folly of their ways.

From 50 to 15

Cutting the number of sizes of pneumatic tires from over fifty to fifteen is another possibility of the work of the Standards committee. This, too, is a possibility because over 85 per cent. of the pneumatic tires now used come within these standard sizes.

Some time ago tire manufacturers voiced the cost of manufacturing and carrying in stock such a variety of sizes and dealers have been loud in their complaints, breathing the difficulties of carrying casings of fifty different sizes and the necessary range of inner tubes to fill such demands. Cutting from fifty to fifteen will take a burden off the dealer, it will make the tire question easier to the car owner, and it will unquestionably result in the better adaptation of stock tire sizes to cars when sold by the maker.

The Safety Valve

But the safety valve is also working in this S. A. E. standardization work, and there is little need of any faint-heart running up the danger signal.

One example suffices: The recommendation to makers to use single-wire installations for lighting and starting instead of two-wire systems brought this out excellently, and although the sub-committee made such a recommendation, the society in session refused to ratify it and passed the subject over as a progress report.

Two Blades of Grass

"MAKING two blades of grass grow where one formerly grew," is a high ideal in productiveness as voiced by President Leland in his presidential address to the Society of Automobile Engineers.

This a high ideal for the agriculturist, and metaphorically speaking it is an equally high ideal in the engineering field, in the production field and in the selling field.

Designing one part that will do the work of two, is but another adaptation of this two-blade policy.

Making one pound of steel go as far as two is another chapter in this simple theory of the agriculturist.

Making 1 gallon of gasoline go as far as 2 gallons have formerly carried you is another chapter in the story.

So designing your chassis and so manufacturing your tires that one set will approximate the mileage of two must be counted in as but a corollary of the same axiom.

So rearranging your factory assembly methods so that one set of chassis assemblers do practically as much as two formerly did is another application of it.

So improving your machinery that one machine will do the work of two is in the same category of greater efficiency.

Making one dollar go as far as two formerly did is still another phase of the question and the greatest of all to the buyer, who expects for his one dollar as good if not better materials, design and workmanship.

To attain such a goal is no mean task. There is no royal road to such an achievement. By the sweat of the brow and the application of intelligence only can such an accomplishment be realized.

It calls for the concentration of an entire factory organization to bring about such a result. An engineering force working at its own tangent to the general cycle of activity of the organization cannot be possible in a factory that will develop two healthy blades where one formerly grew.

You cannot be a disciple of the two-blade theory and have a designer who sets his back on the practicalities of foundry practice.

43 Per Cent. of Cars in New South Wales Are American

SYDNEY, N. S. W., AUSTRALIA, June 4—The total registration of automobiles in New South Wales from January 1 to May 14 this year shows 8,615 motor cars, 238 taxicabs, and 497 commercial cars.

For the same period the registrations in Victoria, one of the other countries in Australia, are 7,300 motor cars, and 330 commercial vehicles.

Official figures have just been given out giving the complete registrations from January 1 to December 31, 1913, and these show when contrasted with registrations for the first 4½ months this year that these two countries in Australia are buying motor cars at a much faster rate than a year ago.

The total registration figures from January 1 to December 31, 1913, showed 7,641 private motor cars in New South Wales alone. Of this total 3,347 were American cars, this figure representing 43 per cent. of the total.

A further analysis of the 1913 figures shows that in all 283 different makes of cars are registered, and of these there are eighty-seven different makes recorded. These figures do not include motor trucks or taxicabs.

In point of numbers America takes first place, the Ford registrations totaling 1,043. Overland carries off second place with 434. Third place goes to Europe, Renault having 346. America gets back in line for fourth honors, the Hupmobile registrations showing 323.

Some of the other leading American registrations are: Buick, 201; Cadillac, 155; Metz, 99; Maxwell, 88; Chalmers, 76; Studebaker, 75; Flanders, 68; Brush, 62; Empire, 57; E. M. F., 48; Regal, 44; Detroiter, 38; Hudson, 35; American, 30; Oakland, 29; Reo, 28; Schacht, 28; Oldsmobile, 26; Mitchell, 22; Little Four, 22; Holsman, 21; Krit, 16; Jackson, 13; Michigan, 12; Moline, 12; Cutting, 9; R. C. H., 9; Abbott, 9; Rambler, 8; Paige, 8; Everitt, 7; Thomas, 7; Parry, 7; Henry, 6; Cole, 5; Auburn, 4.

There are three each of the Paterson and Stutz.

There are two each of Pierce-Arrow, Kissel, Marion, Coleman, Stanley, Pope, Herreshoff, Cartercar, Dixie, Black Crow, and Lexington.

There are one each of Anderson, Apperson, Colby, Franklin, Havers, Gt. Western, Garford, Jeffery, King, Lewis, National, Norwalk, Pope-Hartford, Pope-Tribune, Premier, Packard, Pathfinder, McIntyre, Pilot, Pope-Toledo, Nyberg, and Winton.

Some of the leading registrations, irrespective of the country in which they are made, follow:

Ford	1043	Austin	146	Empire	57
Overland	434	Minerva	141	E. M. F.	48
Renault	346	Brasier	106	Regal	44
Hupmobile	323	Metz	99	Detroiter	38
Talbot	305	Napier	94	Hudson	35
Star	273	Clement	93	Oakland	29
Fiat	219	Wolseley	88	Reo	28
Buick	201	Maxwell	88	Schacht	28
F. N.	193	Chalmers	76	Oldsmobile	26
Cadillac	165	Studebaker	75	Mitchell	22
Daimler	164	Flanders	68	Little Four	22
Humber	153	Brush	62	Holsman	21

New South Wales is but one of the six countries comprising the commonwealth of Australia. It has a population of approximately 1,500,000, out of a total of 4,270,000 for all of Australia.

Conditions generally in this country at the present time, in fact through all the six countries in Australia, are very prosperous and even the taxation (commissioner's report, on the income tax) proves that all of Australia is passing through a period of record prosperity. There is every indication of a similar season ahead.

Knight Motors Built for Trade

Moline Co. Decides to Utilize Full License Perquisites with R. B. McMullen as Sales Agent

EAST MOLINE, ILL., June 30—The Moline Automobile Co. of this city is going to build Knight sleeve-valve motors for sale to the motor trade, this decision having been made by W. H. Van Dervoort, president of the company, last week.

The Moline company, while extending its activities in this way, will not drop its car manufacture, but solely utilize to the full the capacity of its motor plant, which will be 20,000 per year, without any additions. The motor department of the Moline company has been in the gasoline motor field for many years and last season marketed over 18,000 motors of one type or another.

For the present its Knight sleeve-valve motor activity will be confined to one model, a four-cylinder design, 4 by 6 inches bore and stroke, this being the same motor that so successfully went through the 336-hour test in January at the laboratory of the Automobile Club of America, New York City. It is reported that a smaller size is at present going through the engineering department. Deliveries will be made practically immediately on the 4 by 6-inch size.

While the manufacture for the trade will be carried out entirely by the Moline company, the marketing of these motors will be looked after exclusively by Robert B. McMullen, Edison building, Chicago, and with a branch office in the Ford building, Detroit. Mr. McMullen for years has been marketing to the manufacturing trade various car parts, such as frames, motors, axles, etc. He thinks that there has not been any more opportune moment for a firm with Moline's reputation as a motor builder to enter into the work of supplying Knight sleeve-valve motors to the trade. The Moline company has a license from Knight & Kilbourne covering the use of the motor for Moline cars as well as selling it generally to the trade, and Mr. McMullen feels that there is no better motor builder.

Buick, Prosperous, to Make 40,000 Cars

NEW YORK CITY, June 29—The Buick Motor Co., a subsidiary of the General Motors Co., had a prosperous year, according to reports, which state that practically every automobile of the 1914 model has been sold, making a total of 32,000 passenger cars, which constituted the capacity of the company's plant. The company has decided to increase the output for 1915 by 8,000 machines, thereby bringing the total output up to 40,000 cars.

The prices for the coming season will be materially reduced. The runabouts will be scheduled at a price $50 lower than that of last year, touring cars $100 less and the six-cylinder cars $335 less. Last year the price of the Buick B-24 model roadster was $950, the B-25 touring car was $1,050 while the B-55 six-cylinder model cost $1,985.

The 1915 models will have some improvements on the design of the bodies. The body will be built so as to give increased facilities for the doors, and the new six-cylinder car will be equipped for seven passengers instead of five. There will be a few slight improvements on the engine design.

Work on the new cars has been going on for some time, so that now the company is in a position to make delivery of its 1915 models between July 5 and 10.

Motion tq Sell Pope Factory at Auction

HARTFORD, CONN., June 27—Judge William L. Bennett, of the Superior Court in this city, having declined to authorize the receiver of the Pope Mfg. Co. to accept the offer of $1,800,000 made for the Pope assets in Connecticut and Massachusetts, the offer has been withdrawn. It was made by a syndicate represented by George R. Nutter, of Boston, who stated that he appeared for Daniel Gurnett and James T. Putnam, of Boston, and Carl Bonney, of Worcester, Mass.

As no other bidders have thus far appeared, it is regarded as probable that the properties will have to be liquidated by the receiver, and as the bulk of the assets in Connecticut are in real estate and machinery and the demand for idle factories is not keen the liquidation proceedings will, it is believed, be rather slow.

Under the terms of the reorganization which was to have been effected had the court accepted the offer, a new corporation with $2,800,000 capital was to have been formed and $1,800,000 was to have been paid for the Pope properties. Only $400,000, however, was to be paid in cash, the remaining $1,400,000 to be in 5-year 6 per cent. notes secured by a closed mortgage.

Judge Bennett at a hearing last week classed this as speculation, inquiring whether the proposition was not asking the court to allow the receiver to sell the assets on five years' credit. The syndicate, however, stated that it was unable to offer more and the reorganization movement ended at that point. Neither the stockholders of the old company nor the merchandise creditors were particularly impressed with the offer, as the stockholders stood to realize practically nothing and the creditors did not favor being paid in 5-year notes.

Following the refusal of the court to accept the offer, the creditors' committee, representing chiefly banks, moved that the plants at Hartford, Conn., and Westfield, Mass., be sold at public auction. Judge Bennett ordered a hearing on this motion July 2.

According to Edward M. Day, who represented the Pope interests as chief preferred stockholders, the Westfield plant is valued at $1,464,270.47, and that there are accounts and bills receivable of $396,280.33 and cash of $61,221.49. At the Hartford factory, he stated, are bills receivable of $142,231, and $49,000 cash.

New Fischer-Detroit Light Car for $595

DETROIT, MICH., June 29—A new car, the Fischer-Detroit light car, is being constructed in Detroit by the C. J. Fischer Co., a newcomer in the automobile manufacturing metropolis. The little four-cylinder will be made in one standard chassis, having a wheelbase of 104 inches and 56 inches tread. There will be five models of bodies for two and four-passengers, and the car will sell at $595 to $845.

The motor will have 2¾ inches bore and 4 inches stroke, the radiator will be of the V-type, while the clutch will be either a multiple disk or a cone. There will be a three-point suspension. The transmission will be selective, sliding gear, with three forward speeds and one reverse. The propellor shaft made of 3½ per cent. nickel steel, equippd with Spicer universal joint. The rear axle is of the semi floating bevel gear type, with Hyatt roller bearings on the live axle shaft, which is made from 3½ per cent. nickel steel and has double row of ball bearings on pinion shaft. Front springs are semi-elliptic and the rear three-quarter elliptic, standard.

The bodies are of the streamline type, interchangeable with the standard chassis. Model A is a two-passenger speedster, model B a two-passenger tourist, model C a two-passenger cabriolet, with disappearing window and collapsible top, model D a four-passenger tourist with single door, one man top, and model E a four-passenger sedan. Models A, B, C, have 30 by 3 inches tires, and models D. E, 31 by 3½ inches tires. All have 30 by 3 inches artillery wheels, with standard demountable rims.

Standard electric generator system consisting of two headlights and one rear light with connector switch will form the lighting system. The fenders will be of the semi-crown type, black enamel finish.

The equipment will consist of standard electric starter and generator, electric lights and battery, ammeter, speedometer, extra rim, tool kit, jack pump, top, envelope and windshield.

Model A and B will sell at $595, model A will have Houk wire wheels, set of five, standard equipment but no top or windshield. Models C and D cost $645, and model E $845, all F. O. B. factory.

Van Patten Gets Larger Territory

NEW YORK CITY, June 29—L. A. Van Patten, New York City distributor of the Saxon car, has been awarded five new counties in New Jersey in which to sell his car. The new territory includes the following counties: Union, Essex, Morris, Somerset and Middlesex, taking in the cities of Newark, Morristown, Plainfield, New Brunswick, Elizabeth and Perth Amboy. There are at present twenty-seven dealers handling the Saxon in his territory. He expects to increase the number to thirty-three. In addition to the new territory awarded to Mr. Van Patten, he controls the following: Greater New York and Long Island, together with Rockland, Putnam and Westchester counties in this state, and part of Duchess and Sullivan counties; and Fairfield and Berkshire counties in Connecticut.

Houpt Acquires More Territory for Lozier

NEW YORK CITY, June 26—Harry S. Houpt, the Lozier dealer in this city, has been awarded new selling territory. Not only Philadelphia, but the eastern half of Pennsylvania, the whole state of Delaware, the east coast of Maryland, with the exception of Baltimore and Washington, and the southern half of New Jersey, has been put under his control.

Buys Flanders Mfg. Co. Forge

PONTIAC, MICH., June 25—The Pontiac Drop Forge Co., has been organized in Pontiac, Mich., its capital stock being $112.500 and its officers, M. Rothschild, president; E. P. Waldron, vice-president; A. G. Griggs, secretary and D. C. McCord, treasurer. These officers with F. H. Carrol compose the board of directors. The company has purchased the drop forging plant and equipment of the old Flanders Mfg. Co. and has now one of the most complete forge plants in the country equipped to any and all kinds of carbon, alloyed steel and copper forgings with heat treatment treating and carbonized departments in connection. J. M. McGrieve, well known in the forging trade is superintendent of the works. The company has its headquarters in Pontiac and will start operations at once.

Savage 20 to Sell for $650

DETROIT, MICH., July 1, *Special Telegram*—Final organization of the Savage Motor Car Co. has taken place. Delbert H. Cummings is president and general sales manager; E. E. Taylor, vice-president; R. W. Fishback, treasurer, secretary and general manager. Headquarters have been secured at 60 Lafayette avenue. Although the plant will be in Detroit, the selection of location has not been decided. The car will be known as the Savage 20 light car, costing $650. It will have a four-cylinder motor, 3 3-8 inches bore, 4 1-4 inches stroke and weighing 1,600 pounds. Only one chassis model and body will be constructed for the present, wheelbase being 108 inches and 56 inches tread. First car to be out about August 15. The concern has been nominally capitalized at $10,000.

Hurlburt to Operate Bus Lines

NEW YORK CITY, June 30—The Hurlburt Motor Truck Co., this city, has started an innovation in the way of catering to the pleasures of the men down in the Wall street district. It has started a line of buses running from Wall street in the afternoon up to the Polo Grounds. At night a number of buses will leave Times Square for Brighton Beach, stopping at the Hotel Shelbourne.

FINDLAY, O., June 26—Ray Austin, previously connected with the Studebaker Corp. and the Amplex Motor Co., has been appointed assistant engineer for the Grant Motor Co.

New York Garage Men to Increase Rents

NEW YORK CITY, June 30—The West Side garages in the city of New York have undertaken to make storage a paying part of the business and to reduce the heretofore unduly large profit on gasoline. A committee of the West Side garagemen met yesterday afternoon, June 29, in the Apthorp Garage, 214 West 80th street, and each man agreed to canvass a certain section of the city on the West Side between 8th and 116th streets and endeavor to induce all garages to raise storage $5 a month and charge a 5 per cent. profit on gasoline. The new rates, if adopted, will be $35 for open cars and $40 for closed cars in the older style of garages and $40 and $45, respectively, in new and first-class buildings. The West Side garages have reduced their prices on "gas" 2 cents, following the recent reductions by the oil company, making the retail price now 22 and 23 cents, according to location.

ST. PAUL, MINN., June 26—L. C. Erbes, 1479 Minnehaha avenue, who recently bought the Dilver Mfg. plant, 2654 University avenue, will manufacture commercial cars and Bob Burman's racing car. Mr. Erbes, who is associated with Burman, has bought practically the entire outfit of the Bull Moose Outing Co., Jackson, Mich., and has ordered it shipped to his St. Paul factory. He plans to begin operations in 90 days and to make up to 250 commercial cars a year and six racing machines.

Hurlburt bus for service in New York City

Big Plant Bought by Chevrolet Co.

Old Maxwell-Briscoe Factory at Tarrytown, N. Y., Acquired for Eastern and Foreign Trade

NEW YORK CITY, June 28—W. C. Durant has purchased the old Maxwell-Briscoe Motor Co.'s plant at Tarrytown to build Chevrolet cars so as to supply the demand on the Atlantic Coast and also the export trade.

Mr. Durant states that the Fifty-seventh street plant in this city and the Tarrytown plant will be combined under the New York management to build the right-hand Chevrolets. After alterations, etc., have been completed in the new Tarrytown plant, it is expected that active operations will commence around January 1, 1915. The output is expected to be at the rate of fifty cars a day. The Flint (Mich.) plant is at present turning out thirty-five cars a day, while the output of the Fifty-seventh street plant is about twenty cars.

The Tarryown property comprises about ten acres of land. The buildings comprise about 205,000 square feet of floor space. The property was held at $267,000.

When the Maxwell-Briscoe Motor Co. was in full operation in Tarrytown it occupied two plants, one known as the Kingsland Point plant, the one just sold, and the other known as the Beekman avenue plant, and employed about 2,500 people. After the liquidation of the old United States Motor Co., that company decided to turn back its holdings into the original companies. The Maxwell-Briscoe Motor Co., one of the concerns included in the U. S. Motor Co., decided to concentrate its efforts in the manufacturing of automobiles in its Detroit plant, and offered for sale four of its plants in the East, two in Tarrytown, N. Y., one in Hartford, Conn., and one in Providence, R. I. The Providence plant was sold to the Universal Winding Co., Providence, in December, 1913.

Billings & Spencer Buy Columbia Plant

HARTFORD, CONN., June 29—The Columbia plant was sold this week to Billings & Spencer Co., Hartford, Conn., well known manufacturers of machine and hand tools. This plant comprises about 250,000 square feet of floor space. The real estate has been assessed at $250,000 and the machinery at $100,000. The plant was originally erected by the Pope interests. The Columbia & Electric Vehicle Co., later known as the Electric Vehicle Co., then took it over. This company went into the receivers' hands and was later reorganized and known as the Columbia Motor Car Co. The United States Motor Co. then took it over and in due course it became the property of the Maxwell interests.

Studebaker Six Makes 16 Miles to the Gallon

BUFFALO, N. Y., June 28—Despite the heavy, intermittent rains last Sunday, the Studebaker six averaged better than 16 miles to the gallon of gasoline on the fourth of its five 200-mile runs. The total mileage was 200.6 miles. Twelve and a half gallons of gasoline, 2 quarts of oil and 1 quart of water were consumed. The average mileage secured per gallon of gasoline was 16.04 miles. This beats all the previous records the car has established on this tour. The next run will be made July 5. This will be the last of 200-mile runs of the 1,000-mile economy tour.

SAGINAW, MICH., June 26—The Saginaw Motor Car Co., Saginaw, Mich., which was organized to build a $395 light car, plans to begin operations this month with an initial output of ten cars. If the company's plans mature it will build 2,000 cars in 1915 and employ 300 men. A. R. Thomas, Detroit, and David Cuthbertson are behind the project. The company has secured the Brooks Motor Wagon plant, 200 by 400 feet.

Kissel Truck in Transcontinental Trip

NEW YORK CITY, June 26—A KisselKar truck with a carryall body, will be driven across the continent. Charles Courtney will be the driver. He will probably start late in the summer, and will arrive at San Francisco in the spring of 1915 for the Panama-Pacific Exposition.

A Commission to Regulate Competition?

In Measure Before Congress, Federal Board Has Power to Prosecute Unfair Enterprises

NEW YORK CITY, June 29—With the object of broadly covering the subject of unfair competition a bill is now on its way through Congress creating a Federal Trade Commission, which would have powers of investigation into instances of unfair competition by corporations. The measure is regarded as preferable to certain other statutes regulating business conditions in that it attempts to lay down no hard and fast rules or definitions, but gives to the commission those powers which now are vested in the Bureau of Corporations. The measure is substantially like the unfair competition law of Germany. None of the expense attached to investigations falls upon the little business man; it is all borne by the government. If any corporation believes the commission has been mistaken in its rulings or orders, the offending corporation need not discontinue its practices, but may go ahead and leave it to the commission to bring a court action. Any employee of the commission who divulges any information not within the line of his duty shall be subject to a fine not exceeding $5,000 or by one year's imprisonment or both if he is convicted.

An extract from the law follows:

Provide: That unfair competition in commerce is hereby declared unlawful.

The commission is hereby empowered and directed to prevent corporations from using unfair methods of competition in commerce.

Whenever the commission shall have reason to believe that any corporation has been or is using any unfair method of competition in commerce, it shall issue and serve upon such corporation a written order, at least thirty days in advance of the time set therein for hearing, directing it to appear before the commission and show cause why an order shall not be issued by the commission restraining and prohibiting it from using such method of competition, and if upon such hearing the commission shall find that the method of competition in question is prohibited by this Act it shall thereupon issue an order restraining and prohibiting the use of the same. The commission may at any time modify or set aside, in whole or in part, any order issued by it under this Act.

Whenever the commission, after the issuance of such order, shall find that such corporation has not complied therewith, the commission may petition the district court of the United States, within any district where the method in question was used or where such corporation is located or carries on business, praying the court to issue an injunction to enforce such order of the commission, and the court is hereby authorized to issue such injunction.

Discuss Workmen's Compensation Act

NEW YORK CITY, June 25—The workmen's compensation act was discussed from the angle of the employer at a meeting held recently by the Merchants' Assn. The matter of the desirability of employers insuring through the state fund created by the new law, or through stock insurance or mutual insurance companies, chiefly occupied the speakers.

Edmund Dwight, manager of the Employees' Liability Assurance Corp., stated that he believed some employers would carry their own risks, as is permissible under the law, but they would be few and would include chiefly the very large employers. He stated that it would be reasonably advantageous to employers to take out policies with the state fund. With the stock companies, he said employers would find a protection which is absolutely essential considering the hardships that he was inclined to believe the new law inflicted.

Professor F. S. Baldwin, manager of the State Insurance Fund, declared that the state fund offered very good attractions to employers large or small because they got a rate not obtainable otherwise, were relieved of all further liability, and would get the benefits of dividends and reductions for merit.

Market Reports for the Week

MARKET PRICES in general remained unchanged last week. Tin had a fluctuating week of it and closed at a loss of $.20 per 100 pounds. At the closing on Tuesday, it was slightly firmer, with an active demand for small lots of nearby positions from domestic consumers. Both coppers dropped in prices, due to considerable irregularity in the market. Lead was again steady at $3.90. Cottonseed oil rose to $7.23 a barrel. On Tuesday this product was very dull in the market, there being no interest shown by refiners and an absolute indifference on the part of speculators.

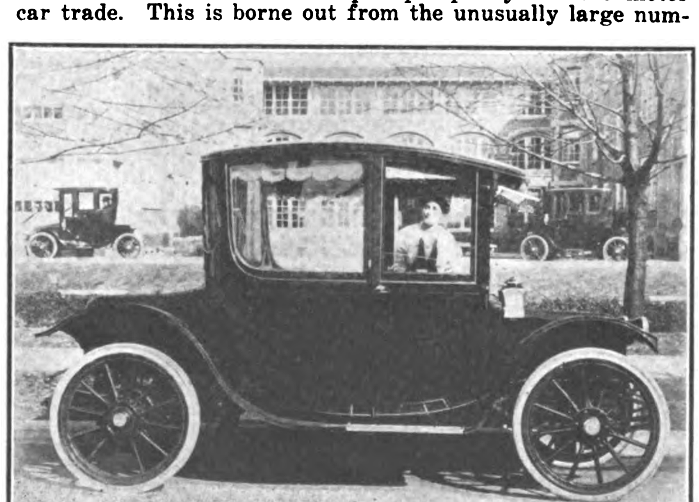
Crops Point to Indiana as Car Market

INDIANAPOLIS, IND., June 29—At the conclusion of a most successful year, the motor car industry in Indiana is looking forward to an even more successful season. In almost every instance dealers have not only sold out their 1914 allotments, but they have been obliged to call on the factories for additional cars.

The reason for the bright outlook is the fact that Indiana will have some of the largest grain crops in its history. The wheat crop, now being cut, is estimated as being twenty-five per cent. larger than that of last year and of much finer quality.

Reports from over the state are that the corn crop is in perfect condition and that a record breaking crop may be expected. Oats are not in as good condition as might be expected, but even at that the crop will be large.

These conditions seem to spell prosperity for the motor car trade. This is borne out from the unusually large num-



New four-chair brougham made by the Waverly Co., Indianapolis, Ind. Note ample window space ber of motor car sales that are now being made in the rural districts and smaller communities and in the many prospects for motor car sales in those localities during the new season.

Automobile Trade Thriving

NEW YORK CITY, June 26—It speaks well for the automobile business that the exports of motor vehicles and parts have shown a consistent increase in valuation over last year when most other manufactured articles ready for use show a marked falling off in exports and when the total exports for 10 months ended with April are less by $59,000,000, or nearly 2.8 per cent., than for the 10 months ended with April, 1913.

Bankers and investors who may have entertained doubts may find reassurance about the condition of the industry in a comparison of exports made by the National Automobile Chamber of Commerce from the current Summary of Commerce and Finance issued by the U. S. Department of Commerce.

Fisk Tire Sizes and Prices Cut

CHICOPEE FALLS, MASS., July 1—Beginning today, the Fisk Rubber Co. makes reductions in certain tire sizes. In plain tread casings the reductions apply only to 3 and 3½-inch sizes; all non-skid sizes are reduced; tubes remain the same.

The 30x3½ plain tread was $17.00; now is........................$16.55
The 30x3 plain tread was $13.85; now is........................ 12.30
The 34x4 non-skid was $36.60; now is............................ 31.60
The 36x4½ non-skid was $46.35; now is........................... 42.65

Rebates will be extended to dealers on any stock on hand at the time of the reduction, provided a serial inventory accompanies the application for rebate. These reductions are said to be due to increased production in the styles and sizes affected. The non-skid production has been practically trebled in the last 60 days.

It is the intention shortly to introduce a non-skid tire, in design similar to the present Town Car Tread, which will be known as the Fisk Red Top. This will be made only in Ford sizes and should prove an attractive seller. Salesmen will show samples and orders can be placed for delivery the latter part of July.

3,408 More Trucks in Chicago Since 1911

CHICAGO, ILL., June 29—There has been an increase of 3,408 commercial cars in this city since 1911, according to figures compiled by Edward Cohen, city collector. During the same period is noted a decrease of 1,789 in two-horse wagons. In April of this year only seventeen four-horse vehicles were in use in Chicago. The 3,408 commercial cars may be divided up into 2,012 delivery wagons of less than 1-ton capacity, while 1,396 are heavy-duty trucks.

NEW YORK CITY, June 26—The board of directors of the United States Rubber Co. have declared from its net profits a quarterly dividend of 2 per cent., on the first preferred stock, a quarterly dividend of 1 1-2 per cent. on the second preferred stock, and a quarterly dividend of 1 1-2 per cent. on the common stock of the company, to stockholders of record at 3 p. m. on July 15, 1914, payable without closing the transfer books, July 31, 1914.

Automobile Securities Quotations

NEW YORK CITY, July 1—The automobile securities market was rather inactive during the past week, a number of the stocks showing no changes whatever, while the majority of those which showed changes experienced slight declines of not over 2 or 3 points, many of them being changes of only a fraction of a point. The only gains to be noticed were: Firestone preferred, ½ point; Gray & Davis preferred, 3 points; Reo Motor Truck Co., ¼; Texas Co., ¼; Overland common, 2 points and Overland preferred, ½ point. There were two or three companies whose stocks showed a considerable drop according to the bid figures but which really remained about the same in general tone. The complete tabulation for the past week follow, giving the quotations for each day and also the 1913 figures:

Seize Automobiles Left Unattended

New York City Street Cleaning Department Enforces an Antiquated Ordinance

NEW YORK CITY, June 29—Just how far public opinion will justify the rule put into force by the Street Cleaning Department of this city on June 27, when twenty-four automobiles left on the streets unattended were seized as encumbrances, is not known, but the move on the part of this department, it seems, is marked by more zeal than common sense.

On that date eight taxicabs of the Mason-Seaman Co. were taken, together with eleven private touring cars and a motor truck. Just what right a public official has in seizing cars is not known, but it looks like confiscation for a person to deliberately step into a private automobile and drive it off to an automobile pound where it is held until the owner pays a fine of from $5 to $10. Such a regulation is obviously intolerable.

The authorities state that it is their desire to discourage the practice on the part of some garagemen of using the streets for repair-shops and wash-stands. Were their activities confined to the extent of which they speak, the opposition aroused undoubtedly would not have been so strong, but the officers seized any and every car found standing at the curb, regardless of how long it had been standing, or for what purpose it had been left, impounded them and required the owners to pay a fine before cars would be released.

Left for 5 Minutes—Car Is Seized

An instance of how far these officials overstepped their authority is shown in the case of a Ford car which stopped in front of the Cutting-Larson Co.'s Oldsmobile establishment. The owner went to the basement for parts, staying about 5 minutes. When he came out his car had disappeared. The officials had hitched a chain and a pair of horses to his car and dragged it away to the encumbrance yard.

There was a Cadillac standing back of this Ford. The owner was inside a repair shop paying his bill for a recent repair done to the car. His car was taken, and he was obliged to travel across the city and pay a fine of $5.

Another instance cited shows how a truck owner was made to pay a fine even when he accompanied the officials himself to the pound. His truck had been standing in front of the White service station and had not been there more than 5 minutes when officers came along and said they were going to hitch chains on it and take it to the pound. Rather than have the vehicle thus treated, they were informed that a chauffeur would drive it to the pound, which he did. He paid his fine, however.

Eleven taxicabs standing at officially designated cabstands were seized if chauffeurs were not with the cabs, even though they were but a short distance away, and these cars were impounded with the others.

Private owners are inquiring how it is to be possible for them to operate their cars in the downtown section and drop into business places unless they go to the expense of employing a chauffeur.

One other thing the automobile owners are kicking about is that they were given no notice of the impounding action.

Means Owner Must Have Chauffeur

With the present New York law in force, an automobile owner is prevented from driving up to an accessory house to buy a tire or anything that he needs, without having a chauffeur or competent driver in the car. Furthermore what is the man who cannot afford a chauffeur going to do? The number of private cars in this city driven by their owners vastly outnumbers either public vehicles or cars, the owners of which hire chauffeurs. Not all the garages or public parking places in the city could supply the need if there should be an endeavor to enforce the rule that cars shall not be left unattended.

J. S. Frazee, president of the Long Island Automobile Club, stated that in his opinion there had been an old ordinance which prohibited the leaving of vehicles standing in the streets without drivers or automobiles without competent chauffeurs, but that it was pretty much of a dead letter. An attempt had been made to enforce it in 1907 or 1908, but after that it was allowed to drop.

That the city officials have aroused the ire of many of the car owners is evidenced by the fact that certain of these owners have threatened to bring suit against the city for alleged confiscation. The Long Island Automobile Club has also announced its intention of entering into the fight against this latest innovation started by the municipal government. It states that should the Street Cleaning Department attempt to force a strict observance of such an ordinance, not only in the business avenues, but in the residence streets and other thoroughfares of the city, it will certainly carry the matter to the courts and have a test case made of the restriction.

Philadelphia Club Insurance Plan Saves 40 Per Cent.

PHILADELPHIA, PA., June 27—A new plan of co-operative automobile insurance restricted to owners of non-commercial cars, which has been in a formative state for about 3 months, has been perfected, the details of which were announced today by the Automobile Club of Philadelphia.

Under the auspices of the Pennsylvania Motor Federation, the Automobile Club of Philadelphia and various other similar organizations, the Pennsylvania Indemnity Exchange has been organized under the laws of this state.

The forms of insurance will cover a wide field, embracing fire, collision, theft, property damage and personal liability, the plan of operation being as follows:

Initial premiums will be based on standard rates of stock companies and a fixed portion of premiums will be set aside for all operating expenses. The balance of the premiums will go into a fund for the payment of losses, and at the end of every 2 weeks such losses will be pro-rated among the members in proportion to their premium payment. At conclusion of policy year each member's ledger account will be balanced and such saving as may have been effected will be returned to the members in cash or credited on the following year's premium, as members may choose.

Minimum expenses for operation, membership limited to the highest grade risks, elimination of stock company profits and rigid inspection of each risk are expected to save members from 20 per cent. to 40 per cent. over the rates of insurance now in force. As no taxicabs or commercial cars will be insured, the extra hazard and cost of insurance for pleasure car owners will be reduced to a minimum. Membership in the Pennsylvania Indemnity Exchange will be open to all owners of pleasure cars.

The Pennsylvania laws require that an insurance exchange of this character must have subscribers for membership the aggregate amount of whose insurance must total at least $1,500,000, thus requiring sufficient risk to produce a fair average. This, together with other safeguards provided, will put the Exchange on a sound basis.

So far the following trustees have been appointed: John B. Stetson, Jr., Alfred R. Wiggan and M. F. Littleton, Jr.

Weed Finally Enjoins Frasse Company

NEW YORK CITY, June 27—Judge Hand, in the U. S. District Court for the Southern District of New York, to-day granted a perpetual injunction in favor of the plaintiffs in the suit of the Weed Chain Tire Grip Co. against the Frasse Co. The Court found that the Frasse Co. had infringed the Parsons patent No. 723,299 covering the well-known Weed Tire Chain construction.

As the Frasse Co. had already settled in full for all damages and profits accruing by reason of past infringement when the injunction was granted no provision is made in the decree for the recovery by the complainant of costs, profits or damages.

The injunction states in connection with the infringement of patent No. 723,299:

"The defendant, the Frasse Co., has infringed upon said Letters Patent 723,299, and upon the exclusive rights of the complainant under same, without leave or license from the complainant, selling cross chains, side chains, cross chain hooks, side chain hooks, German machine chain for cross chains, Triumph chain for side chains, and other material and parts adapted or intended to be used in the manufacture or repair of chain grips covered by said Letters Patent, and aiding and prompting infringement of said Letters Patent by others by offering such parts of material to customers with the advice and recommendation that they be used and with the knowledge that they would be used in making or repairing chain grips and by displaying in connection with such parts and material advertisements that such parts and material were for use in making or repairing chain grips.

"The defendant having settled in full for all damages and profits accruing by reason of past infringement of said patent by defendant and by defendant only and for cost, no provision is made for the recovery by the complainant of costs or of profits or of damages as aforesaid, and this decree is hereby made final."

Stromberg Gets Preliminary Injunction

NEW YORK CITY, June 27—An order has been signed by Judge Hand, in the U. S. District Court for the Southern District of New York, granting a preliminary injunction to the Stromberg Motor Devices Co. against Ludwig Arnson and Alfred Michaelis, doing business as a copartnership under the name of Longuemare Carburetor Co.

The injunction was asked by Charles W. Stiger in an affidavit filed last week, the injunction to restrain the defendants from further alleged infringements of the Richard and Ahara patents pending the settlement of the suit.

Several other affidavits were filed last week as follows:

John A. Dienner deposed under date of June 24 that he was employed from June, 1910, to January 3, 1914, in the United States Patent Office as assistant examiner, and in the course of his work was unable to find the alleged French patent No. 238,392 of May 28, 1894, entitled Pour moteur à petrol à alimentation pneumatique regulable by F. B. Poerschmann. In the records of French patents in the Public Library of Chicago he was unable to find specifications or drawings corresponding to this. In the British Patent files the application by Poerschmann No. 12,390 and dated July 26, 1894, was marked abandoned. In the German files there is no patent of corresponding subject, matter and title according to Mr. Dienner. The Poerschmann patent is alleged by the defendants to antedate the Ahara and Richard patents.

Kempster B. Miller, and Raymond M. Anderson state in an affidavit that they never heard of a device in practical use called by the name of Poerschmann and that they did not believe there ever was made a practical and operative structure such as that set forth in this so-called French patent. They also aver that the Poerschmann construction certainly does not have the construction or mode of operation, nor can it secure the result of the inventions of the Richard and Ahara patents in suit. After explaining the alleged and practical features of the Poerschmann construction and their wide difference from the Richard and Ahara patents, Messrs. Miller and Anderson point out fifteen points of identity in construction and operation alleged to exist between the Ahara and Richard patents on the one hand and the Longuemare on the other, and state that not one of these essential points is found in the so-called Poerschmann patent.

Can't Sue Employers Insured Under State Fund

NEW YORK CITY, June 26—According to a new ruling recently announced by the Workmen's Compensation Commission, it is stated that employers insured under the state fund for hazardous occupations will be protected from all civil suits for damages by injured employees.

Section 53 of the Compensation act gave the employer full protection from damage suits, the commission said. By special resolution the commission set forth both the text, and this interpretation of the section:

"All employees of an employer, whose business is a hazardous employment within the meaning of the Workmen's Compensation Act, are held by this commission to come within the provisions of the act, and therefore have no right to bring action for damages against their employer on account of injuries received in the course of employment."

Asks Bill of Particulars in Shim Suit

NEW YORK CITY, June 29—In the suit of Eric G. Lindhe against the Laminated Shim Co. brought May 23, a motion for a bill of particulars has been endorsed by Judge Hand, in the U. S. District Court for the Southern District of New York. Thirty days are given to serve the bill of particulars with leave to the plaintiff to enter an order vacating the order, taking the counter claim pro confesso and to reply thereto within 10 days after the filing of the bill of particulars.

Supreme Court Finds State Law Supreme

CHICAGO, ILL., June 28—That this city cannot make regulations inconsistent with the motor vehicle act, has been held by the Illinois Supreme Court, in a suit brought by the City of Chicago against C. R. Francis. It was also held that an ordinance requiring the owner of a motor vehicle, not a motor truck or a motor-driven commercial vehicle, to display numbers other than the number of the registration seal issued by the secretary of state, is void.

Under the present motor vehicle act a city may make and enforce reasonable traffic and other regulation except as to rates of speed, provided such regulations are not inconsistent with the motor vehicle act and the conditions are such as to warrant them.

Garages Gain in Separator Case

Testimony That Little Gasoline Reaches Sewers Impresses New York Board

NEW YORK CITY, June 30—The Welfare Committee of the City Council, before which the question of oil separators for garages has been under investigation for some time, has reported favorably to the Board of Aldermen of the city on the resolution of the dealers and garagemen of New York to the effect that the section of the municipal code calling for the use of oil separators be eliminated.

The question of oil separators is a long mooted one in New York City and there are at present some seventy or eighty suits for failure of garage men to use separators in the courts. It was not until the New York dealers took the matter up actively that this Welfare Committee gave it serious attention. The dealers employed expert chemists to make analysis on the value of these separators and it was reported the value was so slight as to be negligible. The dealers' other basis of complaint was that there was not any necessity for separators. The matter will next come before the entire city council.

At the last hearing on June 26 Attorney Charles Thaddeus Terry led the forces of the New York Garage Association, the Automobile Dealers' Assn. of New York City, Brooklyn Garage Owners' Board of Trade, the Brooklyn Motor Vehicle Dealers' Assn. and the American Automobile Assn.

Dr. Russell W. Moore, the fire department chemist, testified that in 307 working days there were taken from forty-seven garages about 3,500 gallons of separator refuse, which was 40 per cent. gasoline.

Trying Out Electrics for Taxicab Service

NEW YORK CITY, June 29—Whether or not the electric vehicle will supplant the gasoline car at the taxicab station at the Grand Central Depot is not as yet determined, but there is a possibility of it so doing. Since June 19 a Rauch and Lang electric has been in regular public service at the Grand Central station. This cab is fitted with a landaulet type of body, with a seating capacity for five passengers, and facilities for carrying truck and luggage.

There is a depression on the Vanderbilt avenue side of the station, suitable for taking on passengers and also for storing the taxicabs. Some doubt has arisen as to whether gasoline cars may be kept there on account of the close proximity to the Hotel Biltmore, and also on account of a clause in the city statutes against storing or running gasoline motors underground or under an inclosure. An investigating committee has been formed consisting of Messrs. Whaley of the N. Y., N. H. and H. Railroad, Katte, chief engineer of electric traction of the N. Y. Central lines, and Miles Bronson, manager of the Grand Central Terminal Assn. This committee expects to make a definite statement in about 2 months.

New Tax Rate Proposed for D. C. Motorists

WASHINGTON, D. C., June 30—*Special Telegram*—An increased tax for District of Columbia motorists is proposed by Congressman Page, of North Carolina, in a bill introduced today. The tax funds are to maintain roads outside the city fire limits. The bill provides tax of $5 a year for cars of twenty-five horsepower and under, $7.50 for cars from 25 to 40 horsepower, and $10 for more than 40 horsepower. These rates will apply to visiting motorists who keep their cars here more than two periods of 5 days each year. Present law provides license fee of $2 per car, which is perpetual.

Hazeltine Valve Grinder Patent Upheld

NEW YORK CITY, June 26—The Hazeltine valve grinder patent No. 13,421, owned by the Specialty Machine Co., is valid and is infringed by the Ashcroft Mfg. Co., according to the opinion of the United States Circuit Court of Appeals in New York City. The patent is a reissue of No. 918,049, and the defendant had claimed that the lapse of time between the issue and the reissue barred the Specialty company from bringing a suit. The lower court agreed with this and dismissed the bill of complaint, but the appellate court held that since reissue narrowed instead of broadened claims it was valid. It also found the Ashcroft device to infringe.

Boiling Oil Petrifies Track for Sioux City Races

Drivers and Officials Arrive for 300-Mile Grind—Banked Turns Stand 90 M. P. H.

SIOUX CITY, IA., June 29.—The work of grooming the 2-mile speedway for the $25,000 race of 300 miles to be staged there on July 4, has been completed and speed tests on the dirt oval the past few days have developed the fact that some of the fast cars will be able to go into the ten-foot embankment curves at a speed of close to 90 miles an hour. It has been demonstrated that the surface in the stretches is so fast that better than 100 miles an hour can be attained by some of the speed creations.

Thousands of gallons of boiling oil have been poured upon the surface of the track during the past few days, practically petrifying the top soil. The 10-ton steam rollers are being used to level the surface and make the track as hard as macadam. Work on the enormous grand stands has been progressing rapidly and the demand for tickets has been so great that the management is arranging to erect more stands than were originally proposed.

Nearly all of the drivers entered have arrived with their cars. On Monday, June 29, practice began under official supervision. Fred J. Wagner, who is to start the race, arrived in Sioux City on Saturday; also F. E. Edwards, of the technical committee. Other out-of-town officials are expected to arrive today and the early part of the week.

Interest beyond all expectation is being shown in the race in that section of the Middle West. Automobile clubs throughout Iowa and surrounding states are arranging tours to terminate at Sioux City on the night of the 3rd, and all the railroads making connections for Sioux City are arranging excursions within distances of 500 miles.

The entries include Wishart, Mercer; Knipper, Delage; Grant, Sunbeam; Babcock, Sunbeam; Oldfield, Stutz; Anderson, Stutz; Mulford, Peugeot; Burman, Peugeot; Stringer, Peugeot; Patschke, Marmon; Keene, Beaver Bullet; Bauer, National; Le Cain, Chevrolet; Horan, Metropol; Chandler, Braender Bull Dog; Wilcox, Gray Fox; Bennett, Moon; Brock, Ray; Mason, Mason; Callahan, Stafford; Wetmore, Chalmers; Klein, King.

Twenty-five Entries to Date for Tacoma

TACOMA, WASH., June 26—To date there are twenty-five entries for the Tacoma road races, to be held July 3 and 4. A few of the cars have been out for practice spins and have reeled off some very fast laps. On June 22 Brock in his Portland-built special and Cooper in his Stutz sparred for the honor of the fastest lap yet to be run on the new Tacoma speedway, and late in the afternoon Brock won. Cooper did his lap in 1:38 and then Brock sent his car around the track for a lap in 1:36:4-5. Hughie Hughes in a Maxwell made a lap in 1:40. The entries for the Tacoma road races, corrected to June 23, read as follows:

DRIVER	CAR	DRIVER	CAR
Tetzlaff	Maxwell	Carlson	Maxwell
Hughes	Maxwell	Verbeck	Fiat
Kennedy	Chalmers	Taylor	Alco
Klein	King	Cooper	Stutz
Welch	Fiat	Croston	Chevrolet
Terrion	Regal	Pullen	Mercer
Parsons	Franz	De Alene	Marmon
Ruckstall	Mercer	Barnes	Romano
Thomas	Locomobile	Brock	Ray
McGoldrick	National	Smyley	Hupmobile
North	Mercer	Sorell	Fiat
Earl Staley	Studebaker	Dingley	Ono
Malcolm, H. L.	Hudson Special		

René Thomas Feted in Paris

PARIS, June 13—French enthusiasm ran riot when René Thomas and his teammates entered Paris after their victory at Indianapolis. Racing fans packed the inside and outside of Gare St. Lazare to such an extent that special police had to be called up to handle the crowds. Louis Delage, builder and owner of the winning car, accompanied by Madame Delage and by M. Michelat, chief engineer of the Delage company, headed the deputation. Flowers were presented, flags were waved, and men and women alike struggled to kiss the somewhat bashful and embarrassed Thomas. The new Delage racing car for the French Grand Prix next month had been driven to the depot by Bablot, and it was in this machine that Thomas was given a triumphal joy ride through Paris to the showrooms of the Delage company, where champagne flowed freely and speeches were indulged in.

All the drivers who took part in the Indianapolis race are enthusiastic over their reception and the manner in which they were treated in America. Without an exception they declare their intention of coming to Indianapolis next year.

Colorado to Salt Lake Run for August

DENVER, COL., June 25—The formal opening of the Colorado-Utah stretch of the Pike's Peak Ocean to Ocean Highway will be celebrated this summer by a 650-mile endurance and reliability run from Colorado Springs to Salt Lake City. Another run of the same kind and same distance is also being planned from St. Joseph to Colorado Springs, which is the midway point of this 1,300-mile route between St. Joseph and Salt Lake City.

Milwaukee Interclub Reliability Award Reversed

MILWAUKEE, WIS., June 27—A review of proceedings under a protest made by the contest board of the Milwaukee Athletic club has resulted in the award of the Wisconsin Motorist trophy to the Athletic club instead of to the Milwaukee Automobile Club as winner of the second annual interclub reliability to Fort Atkinson, Wis., and return on Saturday, June 20. The motor club won the plaque in the first tour in 1913 and on the face of the returns of last Saturday's run was again named winner, but evidence was dug up by the losers that several observers were negligent and the judges made a new canvass of scores, with the result that the motor club lost by a score of 44 to 2. The original score gave the motor club a victory by a score of 50 to 34.

The Athletic club was penalized originally a total of 50 points by reason of the killing of a duck by No. 14, Cadillac, Robert E. Hackett. Evidence was adduced that a motor club contestant had injured a chicken, but neither driver nor observer were aware of the fact and it was not reported. An athletic club car just behind the offender noted the violation of the rule. This canceled the 50 points against the Athletic club.

First American Cyclecar Reliability Run

NEWARK, N. J., June 26—The Cyclecar Club of New Jersey will hold the first Cyclecar Reliability Tour in America on September 2, 7, and 8, when a 300-mile tour from Newark to Atlantic City via Philadelphia, will be made. A schedule of 20 miles an hour will be enforced with ample checking stations and noon and night controls. Every car will carry an official observer and a close tally on tires and gasoline consumption in each class will be given. Twelve silver cups will be given as prizes to the perfect score cars.

SYRACUSE, N. Y., June 27—M. Burton Coe won the silver trophy in the annual run of the Automobile Club of Syracuse, June 24. The secret time decided upon for the run to Mexico Point was 2 hours and 19 minutes, and Mr. Coe's time was within 1 minute and 2 seconds of being correct. Edward W. Sparkes was the successful contestant for the Watson cup, the four winners of this trophy for the past 4 years fighting it out for permanent possession of the trophy. Sixty-seven cars took part.

Huge oil-sprinkler mounted on motor truck for Sioux City track

Poor Space for U. S. at Paris Show

Under New Rules Only Members of I. U. A. M. Get French Privileges—U. S. Not Asked to Join

PARIS, June 20—American automobile manufacturers are given the alternative of either keeping out of the Paris Salon or accepting third-rate stands under the gallery. Under the new regulations only nations belonging to the International Union of Automobile Mfrs. are allowed to have the same positions as French firms, and on condition that the firm has exhibited in three previous Paris shows. Practically every European country is represented on the International Union of Automobile Manufacturers; thus European firms draw lots for positions at the same time as the French if they have exhibited three times previously, or just after the French if they have not been in the show this number of times. This enables all Europeans to get front row stands in the Grand Palais. America has never been represented on the International Union and is therefore barred from all the better stands.

R. N. Goode, general manager of the Paris branch of the Packard Motor Car Co., declares that rather than accept an inferior stand he will keep out of the Paris show. Last year the Packard company had a big stand in the center of the hall.

F. O. Bezner, vice-president of the Hudson Motor Car Co., sees no hardship in the new arrangement. "Last year we had No. 1 stand," Mr. Bezner stated to THE AUTOMOBILE representative, "which was really better than we could ever have hoped to obtain. This year all the American firms will be grouped. In my opinion this is a decided advantage, for it will help to draw attention to American cars. We have always been well treated by the Paris committee, and I am personally very well satisfied with the arrangement to group us in a second or third rate zone. Every firm in the show gets a big amount of publicity, and if we spend the difference between the cheap and the dear stand in newspaper advertising, we shall get just as much out of the show as the man who has No. 1 stand on No. 1 row."

It is now officially announced that the show will open on October 16 and close on October 26. President Poincare recently received Louis Renault, as head of the show committee, and assured him that he would officially inaugurate the show on the morning of October 16. In addition to passenger cars, the Paris show provides classes for commercial vehicles, motorcycles, cycles, steel and foundry industries, and automobile publications. The Grand Palais will be made use of as on previous years, with a special building for commercial vehicles, if necessary. Applications for space in the exhibition hall are received until July 10. This year's show is under the control of a joint committee representing the various French trade associations, and is conducted on a profit sharing basis. Foreign firms are allowed to share in the profits, but can only secure the highest percentage by obtaining membership in one of the French associations.

C. of C. Willing To Take Space

NEW YORK CITY, July 1—Alfred Reeves, general manager of the National Automobile Chamber of Commerce, when informed of this latest ruling on the Paris show stated:

"Our makers and our organization will gladly take any necessary steps to become members of the N. U. A. M. and will go further and agree on space for all our members, the same as we do at New York shows for all importers. We have not been approached to join the International Union."

105 M. P. H. in Grand Prix Trials

PARIS, June 20—Official trials over the French Grand Prix course were carried out four mornings this week from 3 to 5 o'clock. The course is now closed to all racing cars and will not be opened until the day of the race, July 4. It is evident from the results obtained in the trials that the 1914 French Grand Prix will be the most keenly contested automobile race ever held in Europe. There are forty-one cars of fourteen different makes, representing France, England, Germany, Italy, Belgium and Switzerland. Elaborate precautions are being taken to prevent racing secrets leaking out. The Mercedes cars are housed in a completely enclosed stone garage, with an 8-foot brick wall around it. One guardian sleeps inside and another outside the garage, while as a final precaution a heavy chain is padlocked round the bonnet when the cars are not in service.

In the trials the Delage men made laps in 23 to 24 minutes. The course measures 23.3 miles and is of a very varied nature—winding, hilly, and fast and straight. The Peugeots showed about the same speed. Mercedes did faster work, Lautenschlager going round the course in 20 minutes, and Salzer doing a lap in 19 minutes. Fiat averaged about 24 minutes and Opel was only slightly slower. Jean Chassagne did not attempt any fast work with his English Sunbeam. The drivers of the two Piccard-Pictet cars, fitted with single sleeve motor, were more interested in doing consumption tests and learning the intricacies of the course than in attaining the highest speed. On certain portions of the course a speed of 105 miles an hour was attained by Delage, Mercedes and Peugeot. Owing to the difficulties of other portions of the course, the average speed is not likely to be much above 70 miles an hour. Total distance for the race is 467.6 miles, and cars are restricted to a cylinder area of 274.6 cubic inches.

Saxon Transcontinental Car Reaches Ely, Nev.

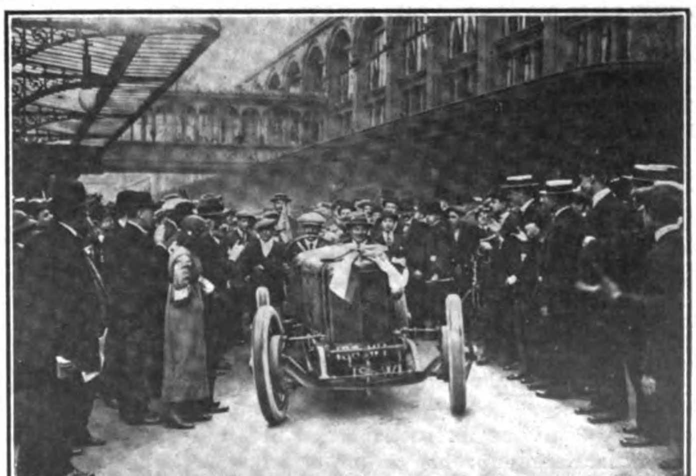
NEW YORK CITY, July 1—The Saxon car, traveling from this city to San Francisco, Cal., reached Ely, Nev., yesterday, after a 156-mile run. The car averaged around 30 miles to the gallon and is adhering to its schedule.

Detroit Electric Breaks Phila.-Boston Record

PHILADELPHIA, June 29—R. L. Heberling, of the Philadelphia Storage Battery Co., conducted an electric trip from Boston to Philadelphia last week during which a new record was made. A Detroit Electric was used. The time between Boston and Philadelphia was 33 hours 50 minutes elapsed time, and only 14 hours 37 minutes actual time, making an average of 25.4 miles an hour.

Master Carbureter Corp. Organized

DETROIT, MICH., June 27—The Master Carbureter Corp. has been organized in Detroit with a capital stock of $250,000 under the laws of Delaware with offices at 944 Woodward avenue. W. E. Burk, president of the Master Carburetor Co., Los Angeles, will reside in Detroit as vice-president and general manager of the new corporation, while W. W. Jenkins, formerly general manager of the Pacific Coast company, will act as general sales manager. The Detroit corporation is entirely independent from the Los Angeles company and has manufacturing facilties for 250 carbureters per day.



Paris fêting Thomas, Indianapolis winner, in Grand Prix Delage

Claims That Makers' Instruction Books Mislead Car Owners

The Automobile Engineers' Forum

Thinks Statements of Care Required for Car Are Exaggerated, Appall the Owner and Result in Neglect in Lubricating the Various Parts

NEW YORK CITY—Editor THE AUTOMOBILE:—In giving directions to owners for the care and especially the lubrication of their cars, manufacturers have almost universally made the mistake of exaggerating the importance of lubricating certain parts and of stating that these parts should be lubricated oftener than is actually necessary.

The purpose of exaggerating, it seems, is to make sure that the owner will not neglect his car, but the directions laid down in the ordinary instruction book are so preposterous that, instead of scaring the owner into lubricating and cleaning his car every few days, he is liable to do just the opposite. By overstating, the manufacturers evidently plan that, at best, a man will not follow the instructions exactly. If the book says the wheel bearings should be lubricated every 800 miles, then he will do it about every 1,500 and if it states that the oil in the motor should be changed every week it will not be done more than once in 2 weeks, or if it says the body should be washed without the use of hot water, soap and a hose the owner will compromise by using cold water and rather weak soap.

Makers' Requirements Too Exacting

But the manufacturers' requirements are so exacting and so different from ordinary practice throughout the country that when the owner receives his machine, instead of trying to follow the instructions given, he gives it up as a hopeless task. The owner realizes if these instructions were taken literally that life would become a burden—not at all what this same maker's catalogue pictured it to be, and the advice of the agent that sold him the car and the advice of his friends all contradict the teachings of the instruction book. Thus the car owner decides that the book is not to be relied upon since his friends' cars are running all right and they do not do all the things required by the makers.

Recently I have had the pleasure of examining several of these books and I found, on the average, that it was necessary to lubricate wheel bearings every 500 to 800 miles, that it was necessary to put grease in the steering gear housing every 300 miles, that the sediment chamber on the carbureter must be drained every 200 miles, that the rims should be graphited to keep them from sticking every 1,000 miles, that after every run the cuts in the tires should be filled, that the various grease cups around the car should be turned every 100 miles and so on.

Owner Ignores Instructions

If the owner followed all these instructions out to the letter he would be crazy in about one week. Instead, he forgets about the instructions and uses his own poor judgment in caring for his car or else he takes the advice of some friend that knows no more about it than he does. The result is that the car is neglected.

It would seem much better, in the light of practical experience, for the makers to be honest about these matters, to state just exactly when the pump shaft grease cups should be refilled and exactly when new oil should be put in the motor, etc. If this policy were adopted the owner would only be too glad to follow the instructions given, he would have confidence in the advice given and his car, instead of being neglected would get the attention it should receive.—M. T. S.

Suggests Making Place for License Plate a Part of Design

BROOKLYN, N. Y.—Editor THE AUTOMOBILE:—Standardization of number plates is a matter that has not received the attention that it should, up to the present time.

There is much to be said in favor of the standardized number plate. In the first place, it would be easier to install or to change the plates when passing into another state. Since the plates would all be the same size, better arrangements could be made for fastening the plates more securely, and at the same time the fastening could be so designed that they could be more easily detached.

A further step would be to make special provision in the design of the car body for the incorporation of the number plates and this would add to the appearance of the car. For instance, a place could be made in the rear panel, for the rear plate and the front plate could be placed at the base of the radiator in a frame that would almost make the plate part of the radiator.

In standardizing, provision should be made for two sizes of plates, one for large cars and the other for cyclecars, as the large plates now used on cyclecars look grotesque. In many cases the front plate is wider than the entire hood.—F. P. W.

Recommends Dimming or Extinguishing of Left Headlight

PHILADELPHIA, PA.—Editor THE AUTOMOBILE:—It would seem to me that the solution of the headlight glare problem lies in passing laws requiring that motorists turn out, or dim, the left headlight when approaching another car. Since the majority of cars are now steered from the left, it is the rays from the left lamp of the oncoming car that blind the operator and by turning this light out this trouble would be overcome.

The position of the headlight rays of two approaching cars, with all headlights burning, and with the left ones turned out, is shown in Fig. 1. Here it will be noted that with the left headlight lit the drivers do not pass out of the influence of the lights until they are almost past, and then it is too late to avoid an accident. However, when the left headlight is turned off the driver passes out of the focus of this light 50 to 75 feet before away from the other car.

This method is superior to using a headlight dimmer because the latter reduces the brilliancy of illumination to such an extent, and so suddenly, that for the moment it is harder to see than before, the eyes being accustomed to the brilliant light, the pupils can not distend quickly enough to enable clear vision when the lights are suddenly dimmed on the approach of another machine.

The question of glaring headlights has become especially acute since left drive has become common, as with right drive the operator passed out of the influence of the left headlight long before the cars passed each other, and therefore some such scheme as I have suggested should be adopted to overcome this evil.—J. T. L.

DETROIT, MICH.—Editor THE AUTOMOBILE:—A means of controlling the cooling of the water in the radiator would be a great advantage.

This is plainly illustrated by the fact that nearly every one resorts to a piece of newspaper or cardboard to be placed over a part of the front of the radiator in extremely cold weather. It also illustrates that a control would not be abused, inasmuch as the practice of closing off the radiator with a piece of paper has not resulted in any complications or difficulties. It would seem that some means of varying the exposed cooling surface, which could be controlled from the seat, would be very desirable and certainly would assist running of the cars in cold weather. In fact, we have foreseen this to the extent of taking out a patent on such a construction some 2 years ago.—GEORGE W. DUNHAM, Vice-president and Consulting Engineer, Chalmers Motor Co.

Finds Reliners Best for Medium-Priced and Undersized Casings

ERIE, PA.—Editor THE AUTOMOBILE:—Our reliners fit all sizes of casing from 28 by 2.5 up to and including 37 by 5 inches. We are using a special fabric in the manufacture of these reliners, which we have adopted especially for this purpose.

We recommend using reliners in casings where the fabric has been injured, also in medium-priced or undersized casings; if tires are oversized, we do not recommend putting in reliners. If used in medium-priced and undersized casings, they will enable the owner of the car to use his casing much longer and will give a large amount of extra mileage.

It is our opinion that the use of reliners saves the car owner a great deal of tire expense, for, as stated above, it prolongs the life of his casing and gives extra service and mileage, at a very small additional expense. We are of the opinion that the sale of reliners is going to show a big increase the coming year over previous years and we strongly recommend them to car owners for practical use.—CONTINENTAL RUBBER WORKS.

Increased Mileage Secured from Old Tires by Inner Liners

BATAVIA, N. Y.—Editor THE AUTOMOBILE:—We make interliners to correspond with the inside of the casing with which it is intended to be used. The material used is friction fabric vulcanized by gum.

We advise the use of liners in old casings only as the applying of liners in new casings is detrimental, both to the casing and to the inner tube. We would not advise the owner of a new tire to use interliners, from the fact that there is sufficient fabric in a first-quality tire to take care of the air pressure necessary to have the tire properly inflated, and an interliner is not at all necessary.

An increased mileage, in our judgment, can be secured from a tire that is badly worn and fabric broken by using interliner, giving quite a considerable additional mileage under those circumstances, well worth the expense of the equipment.

The demand for interliners is mostly on small tires, owing to the fact that the larger tires are used on a more expensive class of cars where the owners will not bother with interliners.—A. W. CANEY, President Batavia Rubber Co.

Thinks Inner Liners Decrease Mileage of New Tires

MILWAUKEE, WIS.—Editor THE AUTOMOBILE:—We are manufacturing reliners for practically all sizes of automobile casings from 28 by 3 to 38 by 5 inches. Reliners for each of the different sizes are built so as to permit a short lapping of the ends when the reliner is inserted in the casing and the width is sufficient to bring the edges of the reliner below the rim contact point and above the toe of the casing.

We are using only high grade fabrics of a consistent tensile strength which is sufficient to prevent the tube from blowing through the reliner even though the casing may be worn or torn so that the reliner itself is exposed.

We do not recommend the use of reliners in new tires. The use of reliners is advisable only to prolong the life of worn casings and is a sort of reinforcement in the case of worn and broken fabric where the motorist does not feel that he has had sufficient mileage from his tire to warrant the expenditure of the price of new tires. Used in new tires the friction necessarily resulting is only harmful to the carcass of the tire and a decreased mileage is bound to result. No matter how carefully reliners may be applied or how skilfully they may be cemented to the inside of new casings the union between the reliner and the fabric of the casing is such that heat is bound to generate and damage result. While it is difficult to determine just what effect the use of reliners has on new casings, we believe that the experience of all tire manufacturers is the same and that if the tire manufacturer felt that the additional plies of fabric in the casing were beneficial to the general result he would adopt a tire built with extra plies of fabric to take the place of the reliner in all casings.

We make no claims for increased mileage in the use of our reliners. The condition of the casing at the time the reliner is applied will have much to do with the mileage resulting from the use of reliners. As a matter of fact, any attempt to make definite claims regarding mileage resulting from the use of reliners is out of the question and statements regarding mileage results obtained are usually visionary rather than real.—FEDERAL RUBBER MFG. Co.

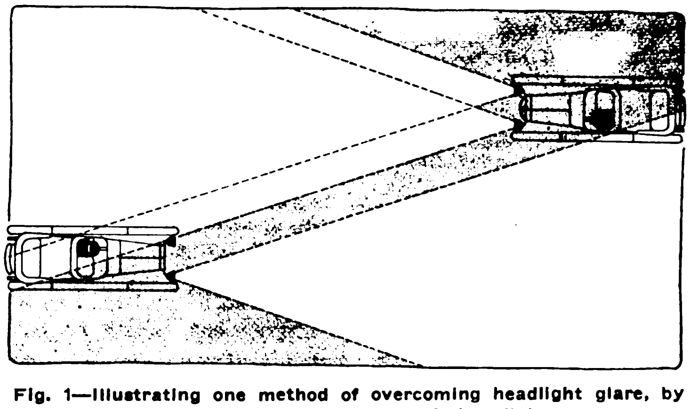


Fig. 1—Illustrating one method of overcoming headlight glare, by dimming or extinguishing left headlight

The Rostrum

Believes in Small Bore, Long Stroke Two-Cycle Motor

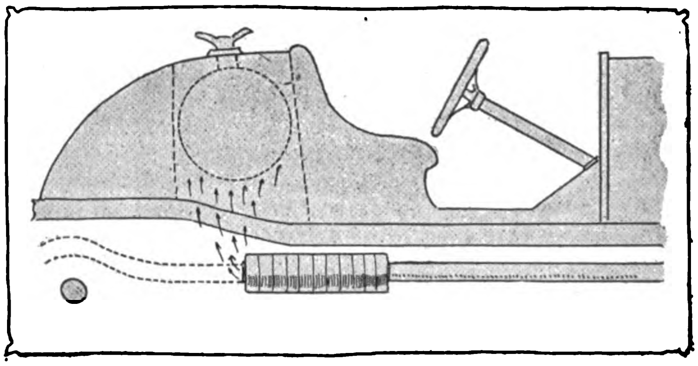

Fig. 1—How broken tail pipe caused fuel to boil and motor to miss

EDITOR THE AUTOMOBILE:—I note with interest that a number of your readers are favoring the two-cycle motor for automobiles, and I wish also to add a few words in favor of the discarded two-cycle motor.

I have a four-cylinder, two-cycle Elmore engine with cylinder compression and rotary valves.

A few days ago I made a trip of 113.5 miles, and before starting on this trip I measured my gasoline, and after arriving home found that the gasoline consumption was 8.67 gallons, or 13.09 miles per gallon.

My car weighs 2,400 lbs. and most of the mileage was between Greensboro and Lexington and from Lexington to High Point, and no doubt many of your readers have been over the National Highway from Greensboro to Atlanta, and if so will agree that the roads around Lexington are about as hilly and trying as any between Greensboro and Atlanta.

The writer is no engineer, but it seems that if an engine of this type were properly developed, a smaller bore and longer stroke used, that better results would be obtained. This type of Elmore engine has a bore of 4 inches and stroke of 3 1-2 inches, and if the bore were 3 3-4 inches and the stroke 4 1-2 inches with the cylinders offset slightly, the proper amount of compression in the lower half of the cylinder determined, an engine would be produced that would have ample power for a 2,400 to 2,600-pound car, and the gasoline economy would be better on account of the greater expansion of the gases.

Another improvement would be to increase the compression somewhat and have the gear ratio of 3.69 to 1 increased to 4 to 1, or possibly a little greater.

You will understand that this type of engine is not suitable for a racing car, but for all around work ideal results could be obtained, as a four cylinder two cycle engine is as flexible as a light six, will run with less vibration and avoid all valve troubles. I hope that some American manufacturer will develop the two-cycle engine as the French manufacturers appear to be doing, as there are possibilities in the two-cycle engine which have never been touched.

We all know what the Diesel engine is doing in stationary engine work, beating all types of engines for economy and thermal efficiency.

Another matter that would need developing with the two cycle engine, would be efficient carbureters. Practically no carbureters on the market today are entirely suited to two-cycle engines when used in automobile work, as the gasoline supply of the two-cycle engine should be decreased slightly as the engine speed increases, on account of the fact that when the engine is running partly throttled a smaller charge is admitted to the cylinders and more burnt gases are trapped than when running with a wider opening of the throttle.

I believe that there is one, possibly two French carbureters made to work on this principle, the wider the throttle is opened the smaller opening the needle valve has, but I do not know of a single American-made carbureter that works on this principle. The Schebler Model D is made with one jet and auxiliary air supply controlled with a coiled spring, and the Planhard has a ball controlled air supply with one jet, and very good results can be obtained with either carbureter, but until there is a larger demand for a carbureter that will give the two-cycle engine more flexibility than is usual in marine work, no particular attention will be given to the development of the perfect carbureter for two-cycle engine work, and ideal results will not be obtained.

Randleman, N. C. R. P. DEAL.

Wiring Lights to Ford Magneto

Editor THE AUTOMOBILE:—1—Will you please publish a diagram showing how to install a low-priced electric lighting outfit operated by the magneto on a Ford 1913 touring car? Where are the wires to be connected for installation?

2—Where can this outfit be purchased?

Allendale, N. J. W. C. TALMAN.

—1—In using the magneto for lighting purposes it is only necessary to run wires from the terminal on the top of the motor to the lamps, the return connection from the lamps being grounded. If the lamps are to be arranged in series, 6-volt lamps should be used and they should be wired up as shown at the top in Fig. 2, while if the parallel arrangement is used the wiring should be as shown at the bottom and 12-volt lamps will be required.

The complete outfit for such an installation can be purchased at almost any supply store for a few dollars together with the necessary switch, bulbs, wire, and reflectors for insertion. The reflectors are arranged to be inserted in the acetylene headlights. Detailed instructions should be obtained from the concern that manufactures or sells the system that you select.

2—If your accessory dealer cannot supply you you can obtain one from the American Auto Supply Co., Chicago, Ill., whose outfit, with kick switch, sells for $3.95; Emil Grossman, New York City, makes an outfit that is listed at $3.45 with 8-inch reflectors; the Fitzgerald Mfg. Co., Torrington, Conn., manufactures an outfit that consists of two brass reflectors, silver plated, a detachable handle switch, Ediswan sockets, oil-proof, cable-cut to the correct lengths; the Excelsior General Supplies Co., Chicago, whose outfit is listed at $7.50, as is that of the R. C. Hull Electric Co., Cleveland, O., and the Auto Parts Co., Providence, R. I., which lists a similar outfit at $3.50; the Motor Car Equipment Co., New York, at $8.50, and the K-W Electric Co., Cleveland, O., at $15, including complete lamps.

Lighting outfits are made in three types by the Vesta Accumulator Co., Chicago. These range in price from $3.80 to $13.50. The two cheaper ones include reflectors for the gas headlights together with the necessary bulbs, wire, switch, etc., ready to install. The $13.50 outfit has a pair of acorn type electric headlights equipped with bayonet lock connectors.

A new Ford lighting outfit involving a patented reflector is marketed by the A. H. Kling Co., Detroit, Mich. These reflectors are silver-plated brass instead of steel, but the special feature is that the back of the reflector is removable so that it is unnecesary to remove the entire reflector in replacing burned-out bulbs. Ease of installation is assured by a complete wiring harness. The outfit, including a flush switch, costs $5, with $1 extra for an Ediswan base tungsten bulb. The Gibson Automobile Co., Indianapolis, Ind., supplies a magneto lighting system with special headlights at $14 and outfits without headlights, but with the parabolic reflectors, from $10 to $17. Some of these comprise the Gibson regulating switch, a $5 instrument.

A complete outfit designed to be installed at small cost is made by E. A. Hammer Co., Cleveland, O. Two types of magneto lighting systems are made by the Auto Parts Co., Chicago. One system is listed at $4.30, the usual outfit of bulbs, wiring and reflectors are supplied, while in the other one listing at $14.40 special bullet type headlights are supplied.

To Keep the Headlight Bulbs from Burning Out

There is one difficulty that is met with in using the magneto as a source of current for the headlights, and that is that the magneto, being designed for ignition only has the property of generating higher voltage as the speed increases so that above 30 or 35 miles per hour the lamps often burn out. It is true also that at low speeds the magneto does not generate sufficient current to make the lamps brilliant. To get around this difficulty there have been one or two regulating devices put on the market which are intended to prevent the excess of current going to the lamps at high speed.

These devices not only prevent the burning out of the lamps, but also permit bulbs of slightly lower voltage to be used so that a good driving light may be had at lower speeds than is possible without them. One of these is the Dean regulite, which inserts a resistance to the current as soon as, and only when, the engine speed and the consequent voltage becomes too high for the lamps. The regulite provides three steps or degrees of action, thereby adapting it to generators of varying capacity. It is made by the Dean Auto Devices Co., Chicago, and is marketed by the Fulton-McCutchan Co., Chicago. An auxiliary which can be obtained in connection with the regulite switch is the Dean speedolite, which is a dash lamp that illuminates the speedometer and acts as a warning should anything go wrong with the regular lighting system. It is supplied at an additional cost of $1.50.

Regulite Has Choke Coil

A similar regulator is the Lite-Controller. The device embodies a choke coil, which generates sufficient back pressure to prevent the light from burning out. Three steps are provided. It is sold at $3 and is manufactured by the American Battery Co., Chicago. Another regulator of this type is made by D. W. McVean, Noblesville, Ind. This, it is claimed, gives a good light at 5 miles per hour, and may be installed by anyone in 30 minutes and sells for $1.50. To reduce the brilliancy of the light for city driving, the Post & Lester Co., Hartford, Conn., is making a controller known as the Dim-Down. It is operated by the driver's foot and lists at $3. A small instrument designed to dim or brighten the headlights is announced by the Suburban Lighting & Gas Engine Co., Toledo, O., under the name of Dimit. The device itself may be placed on the dash and is controlled by hand. The face of the instrument is fitted with a switch and various notches so that the headlights may be operated at full voltage or at intermediate pressure. It is especially applicable to Ford cars and sells for $2.50.

Ford magnetos generate alternating current and for this reason storage batteries cannot be used in connection with them unless some means for changing alternating into direct current is employed. A rectifier for this purpose is manufactured by the American Battery Co., Chicago.

Boiling Gasoline Makes Motor Miss

Editor THE AUTOMOBILE:—A missing motor that was caused by the boiling of the gasoline was a trouble that I had recently and yet if I had not experienced this trouble myself I would not have believed it possible. Since then I have found one other case like it and although this trouble will not visit very many owners it is so difficult to locate when it does occur that a description of my experience should prove of value to some of the readers of THE AUTOMOBILE.

The trouble was all due to the breaking of the muffler tail pipe which allowed the gas to pass directly around the fuel tank. This is clearly illustrated in Fig. 1. The rear of the car is equipped with a turtle deck and the gasoline tank is located right back of the seats and in front of a compartment for tools. The bottom of the space the tank is in, is open, and the top is not air-tight although it is covered over. There is no filler cap on the tank but there is a cover in the top of the turtle deck right close to the opening in the tank. The result was that when the tailpipe was broken off by a blow from the axle, when going over a very severe bump, the gas issuing from the muffler passed around the tank and up through the filler opening and out. Hence after running a few miles, especially on a hot day, the gasoline would boil.

When the tail pipe broke, I left it off for the reason that it did not seem to be of any use and it certainly did not make any difference in the amount of noise the motor made. After that, however, the car would develop symptoms of overheating after running a few miles. The motor would miss, the car would run hard, would not develop its full power and would therefore not climb the hills as it should. It would not run at all below 15 miles per hour on high gear.

Everything seemed to be all right. I noted, however, on stopping for lunch one day that the car ran much better after this rest.

Later, after running the car a few miles in the hot sun, I found it almost impossible to proceed. I stopped the car in a hopeless effort to find out what the matter was. With the noise of the car and engine hushed, I heard a bubbling sound coming from in back of the seats. I turned around wondering what the trouble was, pulled off the filler cap and found that the gasoline was boiling briskly.

A little thought showed what was causing the trouble and I got a large piece of sheet iron and tacked it on the under side of the body in such a way as to deflect the gases to the

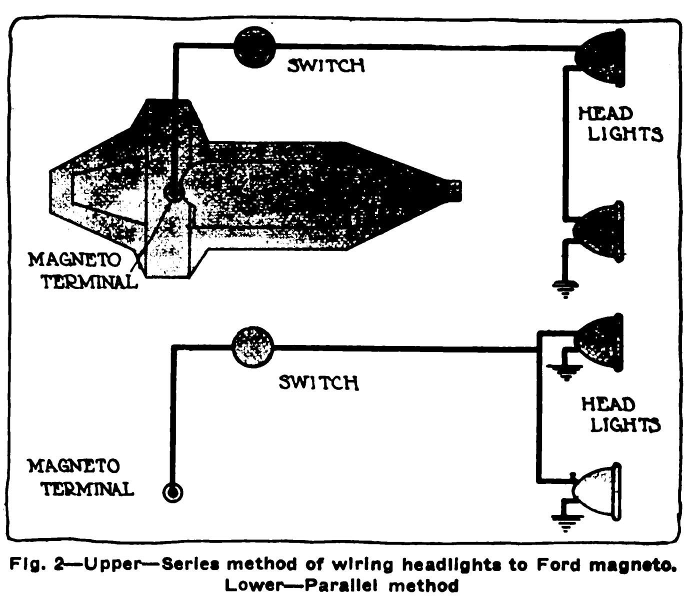

Fig. 2—Upper—Series method of wiring headlights to Ford magneto. Lower—Parallel method

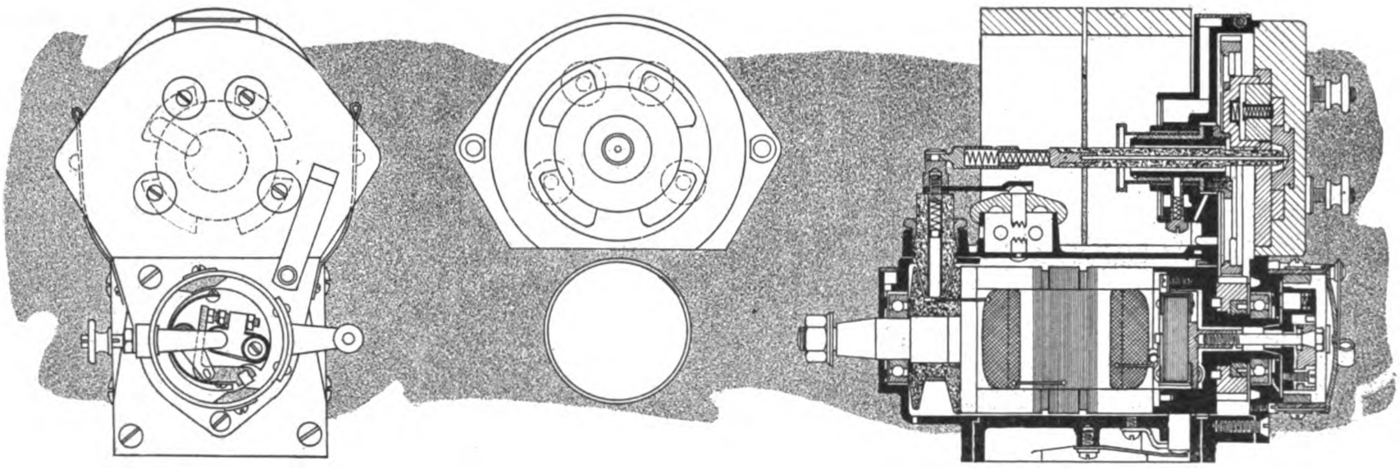

Fig. 3—Front and read, and longitudinal section of magneto showing construction of mechanism

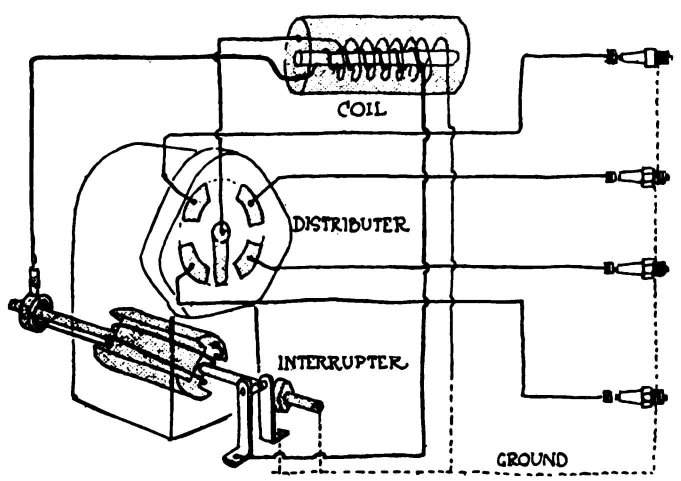

Fig. 4—Diagram showing working of low-tension magneto

rear, and I was troubled no more, the engine running perfectly.

Since then I met another owner that had the same trouble due to the gasoline pipe being close to the exhaust pipe for several inches. As soon as the fuel reached this hot place it would turn into vapor and the motor would miss and sometimes stop.

New York City. R. F. C.

Details of Magneto Construction

Editor THE AUTOMOBILE:—1—Please name each part of the magneto ignition system, and show the construction of each part.

2—What changes take place in the magneto and engine, when the spark is advanced and when it is retarded?

Beaver Falls, Pa. E. S.

—1—Before attempting to name the functions of the different parts of a magneto ignition system, it will be necessary to explain the principle on which the magneto operates.

A magneto is a device that furnishes a spark at the points of the spark plug when the piston is somewhere in the neighborhood of top dead center, between the compression and power strokes, the spark being generated by the rotation of a member called the armature. The spark produced in the armature is of low voltage and must have its voltage raised to enable it to jump the gap of the spark plug. This is accomplished in a coil which may be located right on the armature, or separately from the magneto. In the former case the magneto is known as a high-tension magneto and in the latter a low-tension magneto.

The spark generated in the armature is correctly timed by a device in circuit with the armature circuit which is known as a breaker and which is nothing more than a switch that is operated by a cam on the armature shaft.

The high-tension current as it leaves the coil is switched to the proper cylinder by a distributer.

The two types of magnetos, low and high-tension, are illustrated in Figs. 4 and 5. Turning first to the low-tension type, the current is generated by the rotation of the armature between the horseshoe magnets. The armature consists of a piece of soft iron, shaped somewhat as shown, with a few turns of copper wire around it, as indicated. Since the armature is between the ends of a magnet, it is thoroughly saturated with magnetism. Now when the armature is rotated, the turns of copper wire in the coil cut through this magnetism with the result that an electric current is set up in the windings. The iron of the armature is merely for the purpose of concentrating the magnetism so that the strength of the magnetic field through which the coil rotates is at a maximum. The denser the field the greater the voltage produced in the coil.

When the current is generated it passes through the collector ring and brush at the rear of the armature, up to the coil, where it runs through the low-tension or low-voltage winding of the coil. From thence it passes down through the breaker or interrupter back to the armature again. Ordinarily the interrupter is closed, but when the piston nears the top of the compression stroke and it becomes time for a spark to occur to ignite the charge, the interrupter cam on the armature shaft separates the points of the interrupter or breaker, thus breaking the circuit and interrupting the flow of current. This sudden interruption of the current flow produces a current of very high voltage in the secondary or high-tension winding of the coil, the latter winding being directly outside of the primary. This high-voltage current flows to the spark plug and jumps the gap and thus a spark is produced.

The high-voltage current, produced in the secondary, is diverted to the proper cylinder by a device called a distributer, as previously stated. This consists of a rotating brush that is connected to one end of the high-tension coil. This brush makes contact, one at a time, with four metal segments, 90 degrees apart, each of these segments being connected to a spark plug by means of a high-tension wire.

When the current jumps across the gap of the spark plug it passes through the engine and frame back to the coil, in other words, the return circuit is grounded.

A spark is produced for every half revolution of the armature, therefore in a four-cylinder motor the armature should be run at crankshaft speed, since a spark is required four times in two revolutions or once every half revolution.

The distributer on the other hand should be driven at half crankshaft or camshaft speed for the reason that the brush makes contact with four segments every revolution, therefore if it makes one revolution for every two of the motor, it will distribute the four sparks that are required every two revolutions of the motor.

The distributer shaft must not only run at half the speed of the armature shaft, but the two must also be connected up so that when the breaker points on the distributer separate and the current is thus induced in the secondary winding of the coil, the brush will be on the proper distributer segment.

The high-tension magneto is similar to the low-tension one with the exception already noted, that the coil is located on the armature. In this case, the low-tension winding of the coil takes the place of the armature winding and it is in this that the current is generated. The circuit is broken by the breaker just the same as in the low-tension type and then the high-voltage current is produced in the high-tension winding of the coil, this coil being outside the primary coil and on the armature.

From the high-tension winding of the coil, the current is directed to the distributer through the brush and collector ring and from thence it is distributed the same as in the low-tension system.

Now that a general idea of the principles of a magneto has been obtained the construction of a well-known high-tension magneto will be described. There are so many parts to a magneto, however, that it is impossible to name all the different members but merely the principal ones. For the same reason, it is impossible to illustrate more than the one magneto.

Figs. 3 and 6 show the construction of a high-tension magneto. Fig. 3 shows a front view and a longitudinal section and in Fig. 6 cross sections at various points from front to back are shown. The first view shows the complete magneto as seen from the driving end, and then follows sections four sections and then a rear view with and without the distributer cap.

The principal parts are named and if the principles of operation of the high-tension magneto are understood, there should be no difficulty in comprehending the functions of the different parts on this magneto.

The current is generated in the armature low-tension winding from whence it is carried to the breaker. At the proper moment, the points of the breaker are separated and the circuit is broken, the parting of the points being accomplished by means of one of the cams depressing the bell crank arm of the breaker.

When the high-tension current comes from the armature it is picked up by the carbon brush which is in contact with the slip ring on the armature shaft. From thence the current passes to the distributer brush through the long current conductor and then it is passed to the spark plugs.

Above the armature, there is a safety spark gap so that in case one of the wires leading to a spark plug is disconnected while the motor is in operation, the spark will jump across these points and thus no injury to the armature will occur. Without a gap the insulation would break down.

2—When the position of the spark lever is changed, the time at which the spark occurs in the cylinder is also changed. For example, if the lever is retarded all the way, then the explosion will probably occur a little after the piston passes top dead center or after it has started on the explosion stroke. Some time after the spark occurs, the charge is burned and maximum pressure is developed. Thus, the further the spark is retarded the later, on the explosion stroke, is maximum pressure generated, and combustion completed, with the result that the full expansive force of the gas cannot be utilized, and furthermore, when combustion is occurring, more of the cylinder space is exposed by the piston because the piston has partly completed the out-stroke and this causes overheating.

Now if the spark lever is advanced, the spark will occur before the piston reaches dead center, and if the lever is advanced all the way the spark may occur so far ahead of dead center that maximum pressure will be generated before the piston reaches the top of the stroke with the result that the pressure of the explosion will actually be working against the upward movement of the piston. This causes a loss of power and a knock.

Of course, these remarks only apply providing the magneto is correctly timed.

The ideal condition is to have the spark lever in such a position that the full force of the explosion will take place just after the piston reaches top dead center. In this way the full expansive force of the gas can be utilized and there is no knocking, which might be caused by an early spark nor any overheating, which might be due by a late spark.

The time at which the spark takes place may be changed in three ways, by rotating the breaker box housing so that the position of the cam with reference to the breaker arm is changed, see Fig. 3, by means of a helically cut sleeve inserted in the armature shaft and in this manner changing the position of the whole armature with reference to the motor; and by rotating the magneto housing and thus changing the relative position of the cam and breaker mechanism.

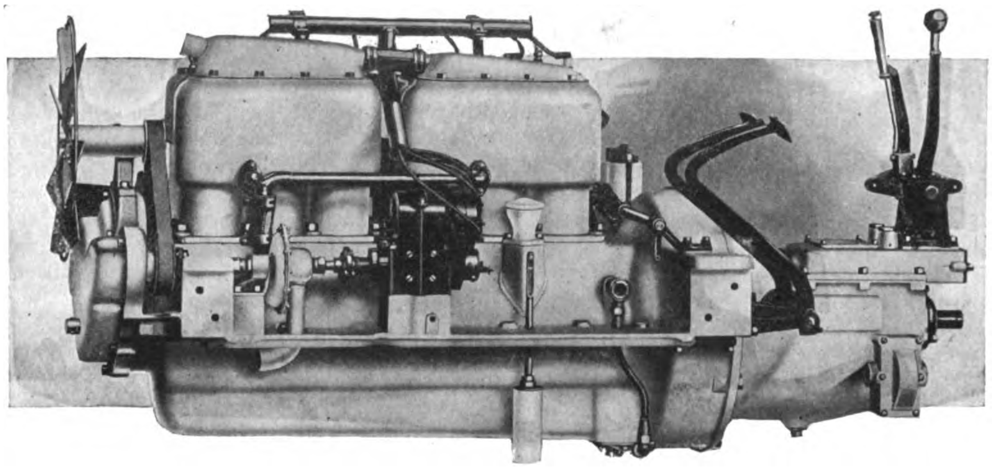
Chandler 2,885-Pound Six Has 10 Per Cent. Power Increase



Six-cylinder motor cast in threes used on the 1915 Chandler six. A silent chain is used to drive the auxiliary shafts

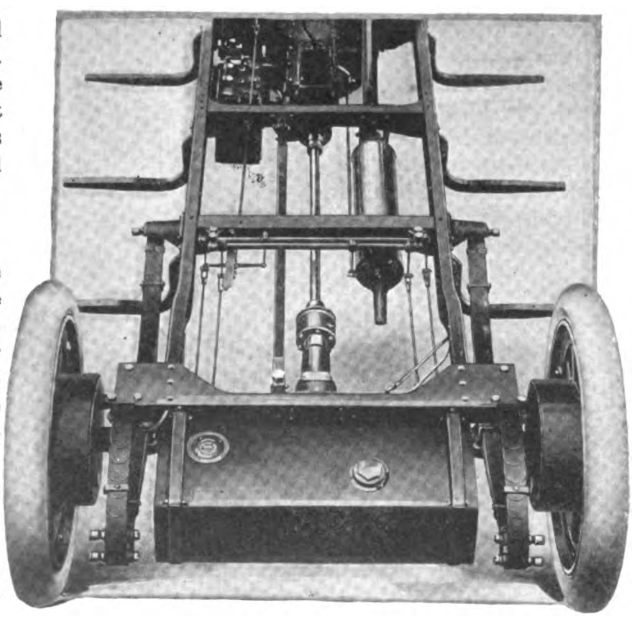
Engineers Have Added to Power Output Without Increasing Bore or Stroke—Silent Chain Camshaft Drive—Two Piston Rings Per Cylinder Instead of Three—Price $200 Lower

WITH the price clipped from $1,785 to $1,595 and with its motor refined to such an extent that 10 per cent. has been added to the power, the 1915 Chandler six has just made its début. The new product of the Chandler Motor Car Co., Cleveland, presents much the same general appearance as did the 1914 model, although several refinements have made it an even better car than its predecessor, despite the fact that its price is considerably less.

The Chandler is a light weight six, tipping the scales at 2,885 pounds fully equipped, and as such meets the growing demand among American buyers for a vehicle which will have a low fuel consumption, which will be easy on tires and which has unlimited flexibility. True, the Chandler is not the only light six in this field, but it is in the front rank. It reflects the policy of a number of well known automobile business men.

10 Per Cent. More Power

In adding 10 per cent. to the power output of the motor, the Chandler engineers have done so without increasing bore or stroke, which remain 3 3-8 by 5 inches, respectively. With these dimensions, the S. A. E. formula accords the engine 27.3 horsepower, but the maker rates it at 35, which is nominal. The motor is built by the Chandler company. In general construction, the power plant remains unchanged, but lighter pistons and a lighter flywheel have been incorporated. The cylinders are of the L-head type and cast in blocks of three. The use of lighter reciprocating parts is a growing tendency, and aids in the securing of better balance and increased speed, both of which factors are conducive to higher power.



Plan view of the 1915 six-cylinder Chandler chassis from the rear showing the new pressed steel torque arm replacing the torsion rod. Note pressure feed fuel tank in rear

The pistons on the new model are fitted with two piston rings each instead of three as formerly. This is a tendency in some of the best designs, and serves to reduce friction to the minimum and at the same time does not allow gas leakage past the pistons if the design is right.

Another change in connection with the engine is the adoption of a Rayfield carbureter. This Rayfield is specially designed for Chandler, and has only two adjustments.

The crankshaft is carried on three main bearings which are of large size and made of white bronze. Their dimensions are: Front, 1 7-8 by 2 1-2 inches; Center, 1 7-8 by 3 inches; and Rear, 1 7-8 by 3 1-2 inches.

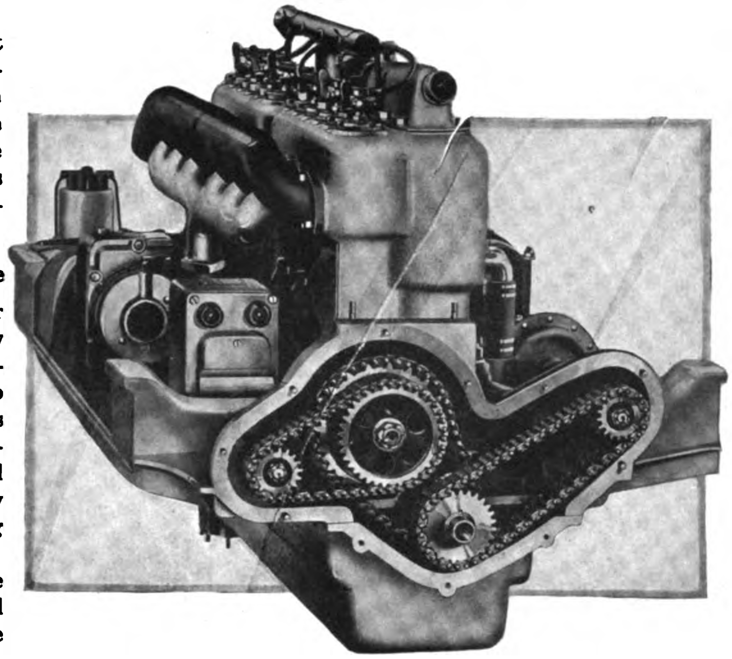
The Chandler company pays much attention to the careful balancing of this crankshaft. The crankpin bearings have the same diameter as the main bearings but are 2 inches long.

The camshaft, which is a drop forging with integral cams, is mounted on three bearings and driven from the front end. It operates the valves in the usual way through tappets. The valves have a 30-degree seat, which is flatter than ordinarily employed. Many makers prefer a 45 degree seat, but the Chandler engineers point out that the angle they employ cuts down the valve lift and the noise without increasing the gas speed. The lift is 9-32 inch. Valves are all interchangeable and are inclosed by cover plates readily removed for inspection or adjustment.

Silent Chain Camshaft Drive

A feature of the Chandler motor is the use of Coventry silent chain drive for camshaft, magneto and pump shaft, and generator. This drive is all completely inclosed at the front end, and its arrangement is clearly shown in the accompanying illustration.

The oiling system of the Chandler motor is a combined force feed and splash type within a constant level maintained under each connecting-rod. A stream of oil is forced by the oil pump to each of the three main bearings, and another lead takes a supply to the chains at the front. All exterior oil piping has been eliminated, and the pump is located in the oil base. An accessible filling tube for putting oil in the reservoir is placed on the left side back of the magneto.



Three-quarter front view of six-cylinder motor used in 1915 Chandler with timing gear case open, showing Coventry silent-chain drive

Bosch Ignition System

The ignition system makes use of a Bosch high-tension magneto in connection with Bosch plugs. The magneto is placed on the left side and back of the water pump. Its bracket is integral with the upper half of the crankcase.

The cooling is improved in that the piping has been changed and the system arranged to give better water circulation. The pump is a centrifugal type, and the radiator a Mayo honeycomb construction.

The electrical system is brought up to the minute. There are separate units for generating the current and for starting. These are of Westinghouse make, and the system used is of the single wire form. Both electric motor and generator are mounted on the right side of the engine, the generator being forward and designed to run at crankshaft speed, which tends to lessen noise and increase the life of the chain driving it.

The starting motor drives through the flywheel and is geared 15 to 1, turning the crankshaft at from 90 to 110 revolutions a minute.

In the headlights there are two sets of bulbs, one set of small size for city driving and the large bulbs for country work. The storage battery is hung alongside the gearbox on the left side and inside the frame rail.

Housed with the flywheel and in unit with the engine is the multiple-disk clutch, which has alternate disks of steel and Raybestos. The clutch mechanism has been improved throughout by the addition of a ball thrust bearing which serves to take the throw-out strain, and reduces friction. The clutch runs in oil.

The gearset, which is also in the motor unit, has three forward speeds and reverse. The gears are nickel steel and the shafts are mounted on F. & S. annular ball bearings. Gearshift and brake levers are mounted directly on the gearcase, thus giving center control.

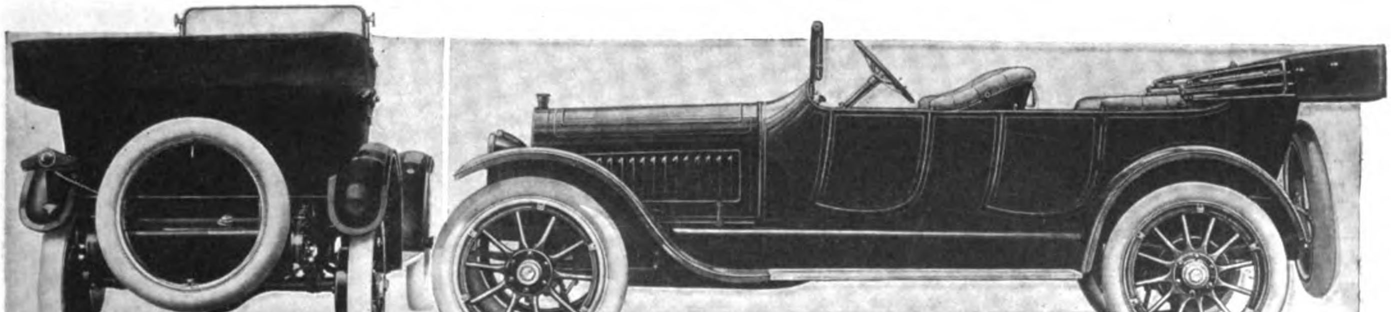
The power goes back to the rear through the medium of an open drive shaft fitted with a universal joint at either end. These are double Hartford universals. A pressed steel torque arm paralleling the driveshaft from the center crossmember back to the axle housing has been adopted. It has a ball and socket buffer construction at the front end, and is hinged at the rear in the usual manner. This type of torque arm replaces the heavier rod construction heretofore used.

The rear axle is a floating type which uses F. & S. annular ball bearings in wheels, shafts and differential. The usual means of reaching the differential unit is employed, whereby a cover plate when taken off exposes the mechanism, which may be removed as a whole without disturbing the rest of the axle after the shafts have been pulled out of engagement. The brakes are of the double internal expanding type, the shoes being faced with a heat-resisting friction material. The drums are 14 inches in diameter.

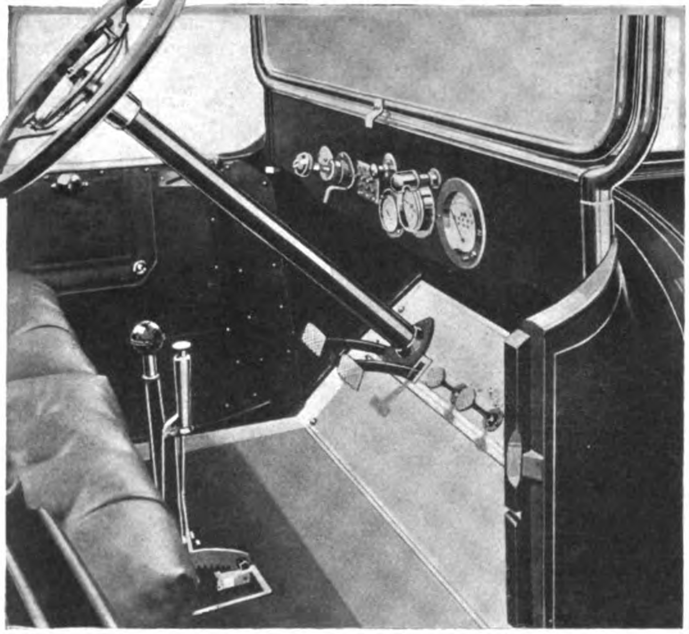
Rear springs, which are mounted outside the frame rails are three-quarter elliptic and mounted over the axle tubes. These, as well as the front half-elliptics, are 2 inches in diameter, and, due to their length, give easy riding.

Pressure Fuel Feed

The gasoline tank is also mounted at the rear and below the chassis level, feed to the carbureter being by pressure from a metal plunger pump on one valve lifter. The tank has a capacity of 20 gallons.



Left—rear view of 1915 six-cylinder Chandler, showing mounting of spare tire on new design tire carrier and also domed fenders. Right—left side of 1915 Chandler six, showing streamline body with clean running board and neatly suspended tire at rear



Control features of 1915 Chandler, showing left drive and center control as well as the arrangement of instruments on the cowl dash

The wheels are of the wood artillery type and carry 34 by 4-inch tires all around. The standard equipment calls for Firestone straight side or clincher, demountable and detachable rims.

The body, which is of streamline design, has undergone little alteration. Clean running boards are obtained through the mounting of the storage battery within the frame and the placing of the spare tire at the rear on brackets which are of a special form designed by the Chandler engineers. The width of the fenders has been increased somewhat, however, and they are of domed form, which is a touch to be appreciated by the fastidious owner.

Equipment Is Complete

The body arrangement is up to the minute. A very neat and symmetrical arrangement of the instruments on the cowl board serves to set off the front compartment, while the rain-vision, ventilating windshield adds its finishing touch. The cushions are 10 and 12 inches, and the seats, front and rear, have high backs which are a feature for comfort. The rear seat is 47 inches in width.

The equipment is complete in every respect. Among the items may be mentioned an electric motor horn, Jones speedometer, New Haven 8-day clock and Jiffy curtains.

The wheelbase is 120 inches and the road clearance 10 1-2 inches.

Beside the standard Chandler roadsters and touring cars, coupé, sedan and limousine models are also furnished or order.

$9,000,000 for Ohio Roads in 1914

COLUMBUS, O., June 26—Fifteen million dollars will be spent for good roads in Ohio this year, according to the estimate of State Highway Commissioner James R. Marker. Of this sum, $9,000,000 will be spent on contracts under the supervision of the state highway department. The remaining $6,000,000 will be spent directly by counties and townships.

A Motor Show at Indiana State Fair

INDIANAPOLIS, IND., June 27—A motor show will be held at the Indiana State Fair, just north of the city, by the Indianapolis Automobile Trade Association. The fair will be held 1 week beginning September 7, and usually attracts thousands of visitors from all parts of the state.

It has not been customary for motor car and allied concerns to exhibit extensively at the fair on account of lack of space. This will be solved by using the immense tent in which the association held a show downtown in the spring of 1912. The tent will be reserved exclusively for exhibits of members of the association.

George O. Wildhack was elected a director in the association. He will fill the unexpired term of R. P. Henderson, who recently became identified with the Regal Motor Car Company, at Detroit, Mich.

Fifth Avenue Buses Carry 1,500,000 in May

NEW YORK CITY, June 26—During May more people used the motor buses on Fifth avenue and Riverside Drive than ever before. The Fifth Avenue Coach Co. hauled nearly 1,500,000 passengers during that month, which is considerably in excess of any previous month in the company's history. The big day of the month was May 3, when 61,400 passengers were carried. This, however, is not the company's record day, as on April 19, nearly 64,000 people were carried, that day being Sunday.

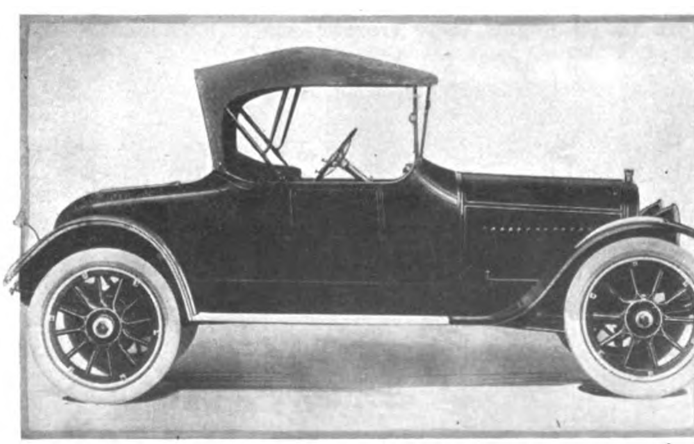
N. Y. Has 27,791 More Cars Than in 1912

NEW YORK CITY, June 26—"Another striking commentary upon the growth of automobilism in New York State," said Mitchell May, secretary of state, "is shown by the registration figures during the last 4 months, when more cars were licensed than for the entire year last past, or 27,791 more than the total number in 1912, when 107,262 were registered.

"At the end of May, 1913, 107,299 machines had been registered, while this year at the same date the number has increased 24 per cent., the total being 135,053. As might be expected, about one-half of these cars, or 62,134, are to be found in the New York district. The number of commercial vehicles in use is already far beyond the total for the whole of last year."

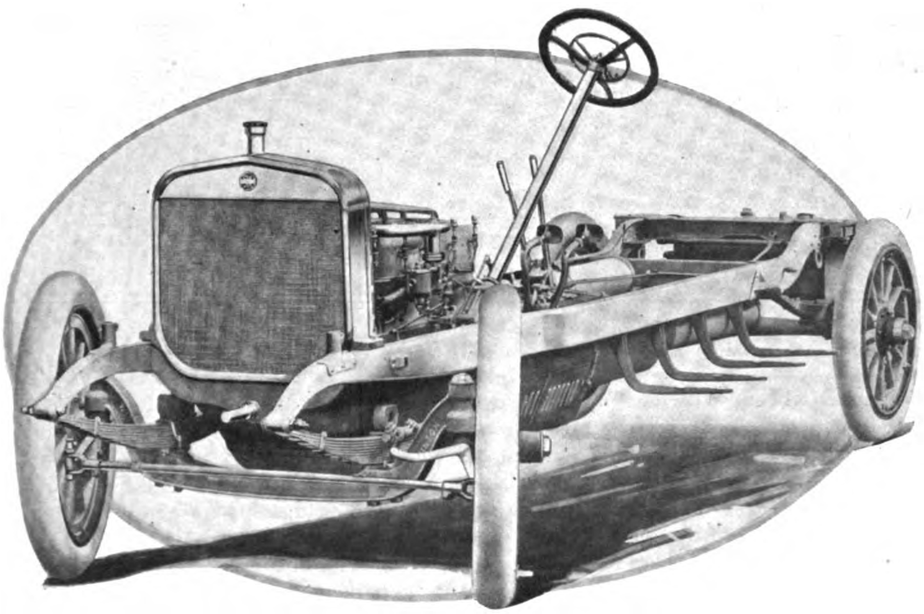
Willard Battery Branches for Europe

CLEVELAND, O., June 26—R. C. Norberg, assistant general manager of the Willard Storage Battery Co., Cleveland, O., sailed for Europe early this month to arrange for installation of a branch of the Willard company and establish service stations in the larger European cities. The company's foreign business has increased very rapidly during the past 2 years and during his stay, Mr. Norberg will visit several existing connections, manufacturers and dealers who are handling or using the company's batteries.



Right side of 1915 Chandler roadster, showing streamline design and ample space provided in rear deck

Winton Minimizes Vibration



Three-quarter front view of 1915 six-cylinder Winton, showing enlarged radiator and more resilient and improved spring construction

All Moving Parts Balanced —New Streamline Body Design—Electric Starting Optional — More Resilient Springs

THE details of the 1915 Winton six, known as model 21, have been made public and indicate that, while the car has undergone very little change mechanically, improved appearance has been obtained by complete re-designing of the body. Besides this, electric starting has been made optional with the purchaser, the Winton air system of turning the crankshaft, which method was used exclusively heretofore, being fitted instead, as desired.

The body retains its streamline effect, while a new beauty has been given it by the raised panel which outlines the upper edge of the body all around. The cowl has been sloped so as to meet the hood, and thus body and bonnet are blended into a smooth-line unit. Greater roominess in the front seat is obtained by this new body design.

Radiator Enlarged to Harmonize

The radiator has been made 2 inches higher and 2 1-8 inches wider, which, of course, means a larger bonnet. This is in good proportion to the body size and gives a pleasing appearance to the whole.

There has been no appreciable change in the engine and its allied units. It has a horsepower of 48.6 according to the S. A. E. formula. The cylinders, which are 4 1-2 by 5 1-2 inches, are cast in pairs with the valves all on the right. The same intake manifold construction is employed, whereby the carbureter is placed on the left side and the two-branch manifold running from it passes over the tops of the cylinders to the valve side where these branches in turn run into a horizontal pipe with an opening into each cylinder block. One change in equipment is the adoption of a Rayfield carbureter.

The Winton still uses the vertically split aluminum crankcase which divides into right and left halves to provide for the ready removal of the crankshaft or other working parts. The main crankshaft bearings are in the right half, allowing the other side to be taken off without disturbing them. In the left half there are three 5 by 8-inch hand holes which allow complete inspection.

The moving parts are all of careful design and balanced so as to reduce vibration to the minimum. The pistons, rings, connecting-rods, and wristpins of any one set are all of the same weight to give this balance; the crankshaft, which is carried on four Parsons white brass bearings, is made of nickel steel; the camshaft and cams are a one-piece forging, the profile of the cams being such as to give a flow of gas proportionate to piston speed. This shaft is removable through the front of the case without any of the rest of the valve mechanism. The valves themselves are 2 inches in diameter and interchangeable. The timing gears at the front are of drop forged steel, spirally cut as a noise-reducing medium and accurately finished.

The Winton system of lubrication is still unchanged. Circulation of the oil is by two pumps, operated by an eccentric on the rear end of the crankshaft. One pump takes oil from the reservoir and delivers it through tubes to the crankshaft main bearings and the timing gears from which points it runs into the crankcase. The other pump draws oil through strainers from the crankcase and returns it to the tank, where it is again strained before use. The oil tank is at the

Left—Universal joint between flywheel and gearbox on 1915 Winton which permits of easy demounting. Right—Rear axle of 1915 Winton, showing strong construction and large brake drums

right of the engine. The cylinders, cams and camshaft bearings get their lubrication by the splash of the connecting-rods, while grooves in the pistons distribute it around the surfaces. To prevent a smoky exhaust due to excessive oil, the flow of the lubricant is regulated by a by-pass in proportion to the motor speed.

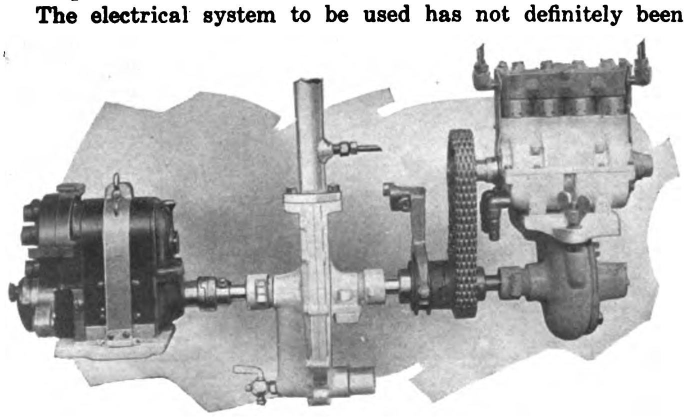
Shield Now Surrounds Fan

The ignition is by either a Mea or a Bosch dual magneto with a storage battery to supply auxiliary starting current. The plugs are still placed horizontally in the cylinders over the intake valves so that they are swept by the fresh incoming mixture. The plugs are 7-8 inch standard. The magneto is placed on the right side of the engine at about mid-distance back, and strapped down on an integral crankcase bracket. It is driven off the end of the shaft which takes care of the centrifugal water pump drive and the silent chain drive to the air pump. This driving assembly is shown in one of the illustrations.

Due to the increased size of the radiator, even greater cooling surface is presented by it, the increase over last season's being about 14 per cent. The fan is driven by gearing which is inclosed at the front end of the engine. This drive has an adjustable spring-tension clutch which is said to secure proper air suction without possibility of accident to the fan or its adjacent parts. The fan is now surrounded by a shield which directs the air to the cylinders and acts as a safety feature. This shield was not used last season.

As already mentioned, the well-known Winton air cranking system may be had, or the engine will be equipped with an electric cranking apparatus. In the air system, there is a pipe connection to each cylinder head, and the pressure from a tank is sent to the cylinders to force the pistons down. This pressure is maintained by a Kellogg air pump.

The electrical system to be used has not definitely been decided upon, several makes being tested out at this time. With the air system a Gray & Davis generator is used for furnishing current for lights. A Willard storage battery is also employed. It is probable that the same make of generator as the motor used for cranking will be installed when this part of the apparatus is decided upon.



Arrangement of magneto pump and tire pump shaft on 1915 Winton. Note the silent chain drive for tire pump

The Winton model 21 uses the same type of multiple disk clutch as its predecessor. There are sixty-three high carbon steel disks, thirty-one of which are attached to the transmission shaft and thirty-two to spiders driven from the flywheel. The unit runs on F. & S. annular ball bearings, while four springs held in pockets and spaced equidistantly around the clutch distribute the disk tension equally. Because the disks operate in oil, there is no jerky action, the oil films having a cushioning effect. The clutch unit is housed in the forward end of the gearcase and is readily accessible through a hand hole.

Four Speeds—Direct on Third

The gearset which is not in unit with the engine affords four forward speeds and reverse, with direct on third. The shifting is selective, the gears sliding. Interlocking arrangements make it possible to enter neutral when the clutch is engaged, but impossible to get any other gear combinations. The gears have wide faces, and are constructed of a special alloy steel.

There is no change in either the driveshaft back of the gearbox or in the rear axle. The shaft is fitted with a cross-type universal at the forward end and has a roller type universal at the rear. The axle is floating and made with a large factor of safety. The differential unit is readily removable, as are the shafts and bearings. Gears are of nickel steel, and Timken bearings are used throughout the rear member. Conventional internal and external brakes operating on the usual form of drums are employed. A torsion rod parallels the driveshaft to take the drive, etc.

Universal Between Clutch and Gearbox

In the transmission of the power back from the engine, there is interposed between the motor and clutch a universal joint similar to that at the rear end of the driveshaft. This is inclosed in a grease-tight metal case, removal of half of which allows the dismounting of the gearbox so far as the front end is concerned. At the same time, it takes care of any possible misalignment between gearset and crankshaft.

Dann Oil Cushion Spring Inserts

The springs are three-quarter elliptic in the rear, and made long so as to give low suspension. More leaves have been added this year, the leaves being thinner. This makes for greater resiliency. The rear springs take the place of radius rods, having no front end shackles, and being suspended outside the frame. The diameter of the shackle bolts has been increased and a new form of rebound straps supplied. A new feature of the Winton spring construction is the incorporation of the Dann lubrication cushion inserts between the leaves. These inserts have pockets of congealed lubricant and keep the springs in good shape at all times. They are standard equipment. The spring sizes are: Rear, 46 1-2 by 2 inches; Front, 52 by 2 1-4 inches.

Tires all around are 37 by 5 inches which is an increase over last season, in that 36 by 4 1-2 inch tires were then used. The wheels are of 12-spoke artillery wood type.

Left Steer and Center Control

Steering is on the left and control in the center, which is well-nigh standard in America now. Spark and throttle levers are on the wheel, which is 18 inches in diameter. A new form of spark and throttle ball joints is now used on the control rods in that they have springs to take up backlash.

The wheelbase is 130 inches on the runabout and four-passenger cars, while the larger types have this dimension increased by 6 inches. Some body dimensions of the five passenger car are: extreme width, 70 inches; distance from dash to seat, 26 inches; height of driver's seat from floor, 16 inches; width of front doors, 22 inches; width rear doors, 24 inches; distance front to rear seat, 33 inches.

The doors have all been widened and are carried on concealed hinges. Handles do not extend through them. Cars having auxiliary seats are provided with inclosed compartments where the seats may be stored when not required. The cowl board fixtures have been re-arranged to give a symmetrical appearance and ultra convenience to the driver, while a tonneau light is also a new kink that will be appreciated.

Prices Are Unchanged

Equipment is complete and includes one-man top, a new design of rain vision glass front, Waltham 8-day clock, tire carriers of a new type at the rear, tire pump, Klaxon horn under the bonnet. Prices are unchanged. The roadster and four-passenger are $3,250; the six- and seven-passenger, $3,500.

Some of the dimensions of the new Winton model 21 follow:

Length of frame rails, roadster and four-passenger cars—179¼ inches.
Length of frame rails, all other models—185¼ inches.
Width of frame front—28 inches.
Width of frame rear—31 inches.
Clearance—9¾ inches.
Optional gear ratios—3.928 to 1; 3.69 to 1; and 3.428 to 1.

The following shows the speed of the car in miles per hour at 1,000 revolutions per minute of the engine:

BEVEL GEAR ON DRIVESHAFT AND REAR AXLE

Transmission	3.928	3.69	3.428
First speed	9.00	9.59	10.32
Second speed	19.42	20.67	22.23
Third speed	28.02	29.82	32.09
Fourth speed	35.28	37.52	40.36

Pa. Creamery Haulage Line Must Pay Delaware License?

WILMINGTON, DEL., June 26—A test of one phase of the Delaware motor-vehicle law is being made through a case brought against two chauffeurs employed by the P. E. Sharpless Co., which has three dairy products factories in Pennsylvania and brings practically all of its products to Wilmington in motor trucks (four tons each) for shipment to Philadelphia by boat. It has no Delaware trade and claims that it is exempt for that reason from Delaware license, through the reciprocal clause in the state law. It operates its trucks on Pennsylvania licenses.

Delaware authorities evidently believe that the company should pay a Delaware license, for the operators of the cars are under prosecution in the present case, charged with operating cars in Delaware without a license, on the ground that the company is making a regular business of bringing its products here.

Philip L. Garrett, counsel for the defendants, claims that his clients are not doing business in Delaware, but are merely engaged in interstate commerce when their trucks come into the city. The court therefore has two points to decide: the extent of the reciprocal clause in the state law and whether the company is doing business here or merely engaged in interstate commerce. Mr. Garrett bases the latter contention on the fact that as Delaware reciprocates all privileges accorded by Pennsylvania it must also include the phase of the Pennsylvania law which exempts all foreign corporations except those doing business in the state.

PEORIA, ILL., June 25—The city has adopted an ordinance prohibiting brilliant head lights on automobiles. The measure is patterned after that in effect in Chicago. A fine of $25 is imposed.

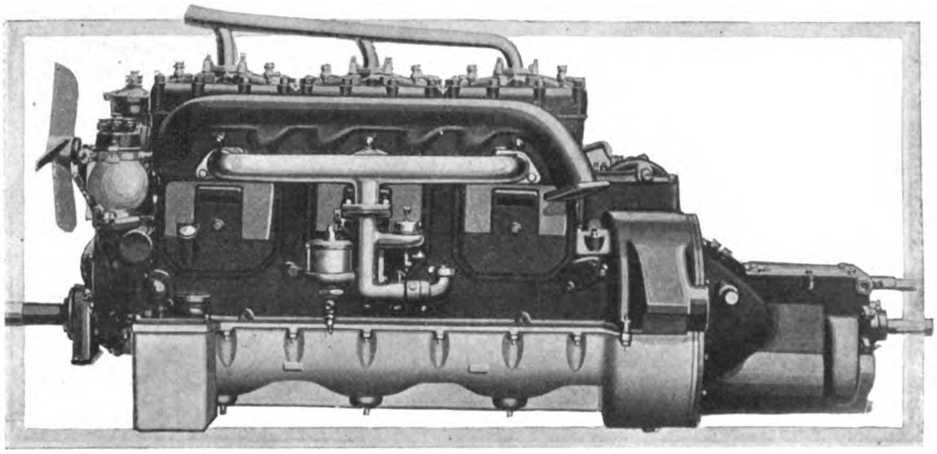
New Cole Little Six Has High-Speed Block Motor

Is Capable of 24 R.P.M. —Streamline Body—Removable Cylinder Heads in Pairs—Few Changes in Big Six Except $135 Price Reduction



Intake side of new Cole little six motor, showing mounting of carbureter on block casting

A NEW model has been added to the Series 10 Cole cars. The newcomer is a little six of practically the same horsepower and almost the same size throughout as the new four announced in April, and described in THE AUTOMOBILE for April 23. The appearance of the little six gives the Cole three chassis models, the Series 10 big six selling at $2,465, a reduction of $135, which is quite similar to the 1914 six-cylinder car, the Series 10 little six at $1,865, and the Series 10 four, at $1,665.

Removable Cylinder Heads in Pairs

The feature of the series is the little six, which has a 3½ by 5-inch I-head motor. The cylinders and the upper half of the crankcase are cast in block, although the removable cylinder heads are in pairs, so that there are three separate cylinder heads, the removal of any of which exposes two cylinders. The clutch and gearset are in unit with the engine, making a unit power plant. The crankshaft is carried on four bearings and a constant level splash-pressure system takes care of the lubrication.

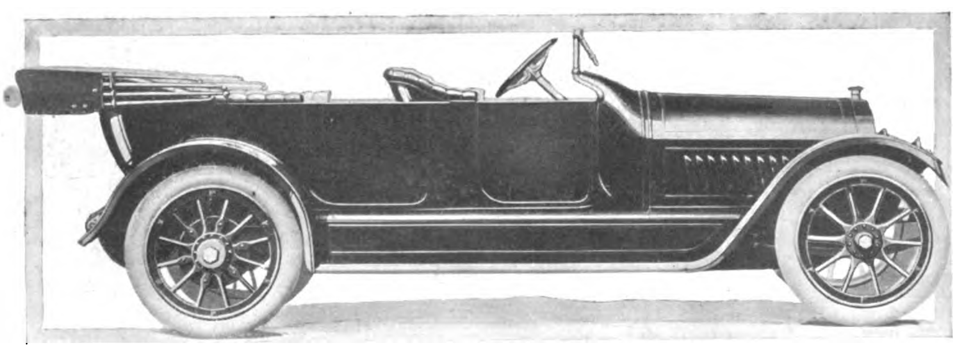
A new feature of the engine is the arrangement of the breathers. Instead of the usual type of breather pipes, an opening is provided through the cover of the valve stems and push rod housing, so that a separate breather is provided for each of the three pairs of cylinders. Carburetion is provided by the new G-2 Stromberg carbureter which feeds through a short-branched intake header. Cooling is taken care of by a centrifugal pump on the right side of the engine, a Mayo cellular type radiator, and a three-bladed aviation propeller type of fan. Ignition is by the Delco electric system with automatic spark advance. The same system supplies the lighting and starting functions.

Long-Stroke, High-Speed Motor

Along with its comparatively long stroke, the engine is of the modern, high-speed type, and is capable of running up to 2,400 revolutions per minute. Block casting of the six-cylinder engine is a departure from former Cole practice, and the little six engine differs in this respect from the big six, whose cylinders are cast in pairs. The reason for this seeming change of heart among the Cole engineers is due to the difference in the size of the engine. With the cylinders 3 1-2 inches bore, it was found that the block casting was not too bulky and heavy to be handled by the average garage, and that consequently the greater rigidity, better alignment, and freedom from vibration of the block casting could be obtained without sacrificing too much through the weight of the casting. In the big six, however, as in the four, 4 1-4 by 5 1-4 cylinders would make too unwieldy a casting, if all cylinders were a unit.

One of the features of the little six engine is the use of large diameter, flexible tubing for the exhaust pipe. This permits long, easy sweeps of the exhaust line and prevents back pressure. The timing gears on the little six engine have spiral teeth.

Aside from the engine, the little six is the same as the four, which has been described previously. The wheelbase is 120 inches instead of 118 inches, the added 2 inches being under the hood, on account of the extra length of the six engine. Briefly, the chassis comprises an improved cone type clutch and a three-speed gearset in unit with the engine, Timken axles and bearings, the rear being floating, service and emergency brakes, contracting and expanding on 15 1-2 by 2 1-2-inch wheel drums, left hand drive, center control, irreversible Gemmer steering gear with an 18-inch wheel, and a carbureter air control located on the steering wheel column.

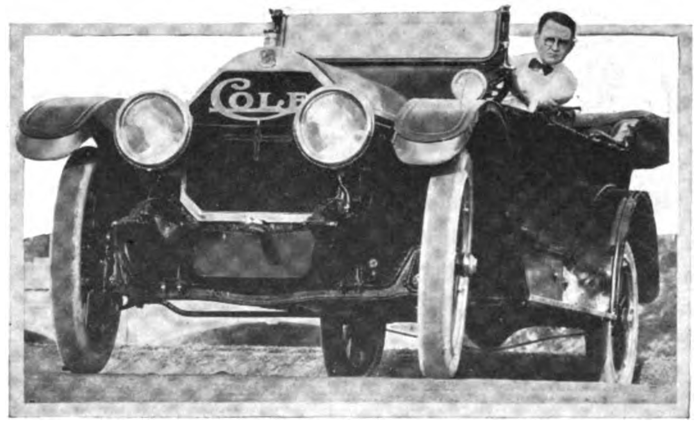


Side view of new Cole little six, showing harmonious streamline design

The frame is a channel section, double drop, pressed steel, extended in the rear to carry the gasoline tank and the tire irons. The fuel tank is a Janney-Steinmetz pressed-steel seamless tank with a circular section. The fuel is fed to the carbureter by the Stewart-Warner vacuum system. The tires are 34 by 4½ inches, mounted on Firestone demountable rims with Firestone tires as regular equipment. The springs are three-quarter elliptic in the rear and are of oil tempered steel. They are the Detroit self-lubricating springs.

Bodies include a two-passenger roadster, four and five-passenger touring and a coupé. The design is streamline with a cowl extended several inches back, 24-inch doors with concealed hinges and locks, straightline splashers and fenders, and long clear running boards. The equipment includes quick-acting curtains, Stewart-Warner speedometer, oil sight feed, all the instruments being set flush in the cowl. The windshield is of the automatic ventilating, rain-vision type. The Delco electric unit cranking, lighting and ignition system is so arranged that the generator cuts in at 300 revolutions per minute, or, at a car speed of under 10 miles per hour. Above that speed it supplies a constant voltage to the Exide battery. The headlights are of the double bulb type, providing a powerful lamp in focus for country driving and a 4-candlepower bulb, out of focus, for city driving. A slight change has been incorporated in the Delco starting system, in that the starting pedal is now separate from the clutch. One of the features which will be appreciated is the adjustable pedal for clutch and brake. These can be adjusted to any length for greatest comfort of the driver.

There has been very little change in the Cole big six, as compared with the construction of the earlier series. The price has been reduced $135, so that it is now $2,465. The chief alteration is in the adoption of the vacuum feed fuel system and the consequent cleaning up of the dash. This eliminates two leads from the carbureter to the reservoir, and does away with the pressure gauge and hand pressure pump on the dash. The motor is an L-head six-cylinder type, 4 1-4 by 5 1-4 with cone clutch and three speed gearset as a unit, the power plant being suspended at three points. The wheelbase is 136 inches and tires are 36 by 4 1-2 inches.



The Cole big six, which is practically unchanged from last year, making a difficult turn

Aside from the equipment as mentioned on the little six, there is added to the big six a Taylor Noil motor driven tire pump. An oil sight feed set flush in the cowl board and the outfit of tools is carried in a drawer under the front seat. The rear doors in this car are 26 inches wide. The bodies include a two-passenger roadster, six and seven passenger touring, a coupé, and a seven-passenger limousine.

New Kissel Kar Six Has Two-Door Touring Bodies

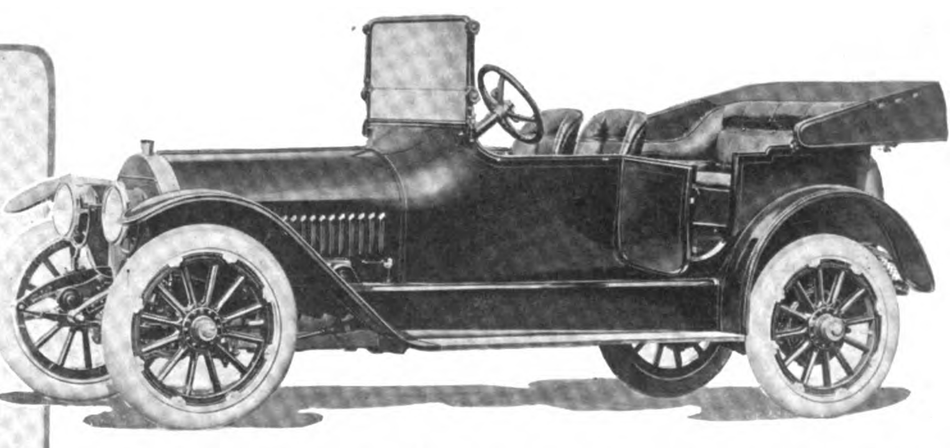
UNUSUAL body design and greater accessibility are the features of the new six-cylinder model recently announced by the Kissel Motor Car Co., Hartford, Wis. This new car will be a part of the 1915 production.

Adoption of a two-door, single-compartment body design is the unique feature of the six. Both four- and five-passenger bodies will be fitted to this new chassis, the four-passenger car differing from the five in that a dividing arm is used between the rear seats.

The two-door body is made possible by the use of individual seats for the driver and his side-passenger, thus making an aisle between. This single-compartment feature allows passengers to exchange seats without leaving the car.

To those preferring a four-door body, two models are offered, one for five and another for seven passengers.

The power plant of the new six consists of a 4 by 5.5-inch motor equipped with a leather-faced cone clutch and a four-speed gearset with direct on third. A noteworthy feature is the position of the push rod which is clamped inside of the valve inclosure. Instead of being pressed into the cylinder the guide, as well as the rod, is accessible for removal without lifting the cylinder from the crankcase.



At the left is a plan view of the new Kissel Kar six two-door streamline body showing the seating arrangement with the aisle between the two front seats allowing the passengers to change seats. At the right is a side elevation of the same car showing the only door on this side of the car open

The Engineering Digest

Minor Innovations in European Cars, Accessories and Parts

ACCESSIBILITY, NEW TOOL, PUMP, LAMPS, MOLDINGS

DISMOUNTING the pistons and adjusting the connecting rod bearings without taking the motor apart otherwise is a mechanical feat which can be accomplished in the case of the British Maudsley motor by virtue of the large gates in the sides of the upper half of the crankcasing and by the method indicated in Fig. 1. By turning the crankshaft to a suitable position, the nuts can first be removed from the connecting-rod knuckle, and by turning the crankpin to the position shown the piston can thereafter be pulled down and out through the gate. The cylinder is chamfered at the bottom to make it easier to get the piston back again.

Pincers have been devised the jaws of which are turned outward and are adapted for holding the free ends of a piston ring a certain distance apart. An adjustment screw serves to fix this distance at just the point at which the ring can be slipped over the piston. By this means all accidental and unnecessary violence to the frail ring is avoided.

According to a 1913 design by Bugatti the water pump is mounted in tandem with the magneto on a prolongation of the crankshaft and draws water directly from the lower

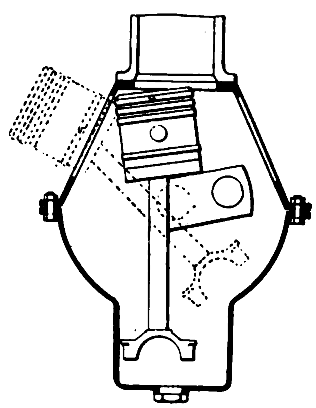


Fig. 1—Mandsley motor

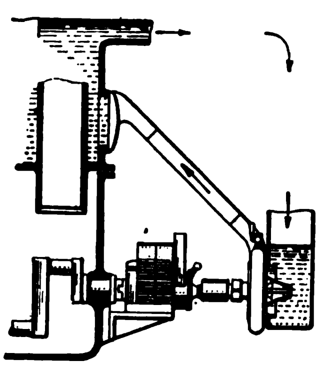

Fig. 2—Pump arrangement

reservoir of the radiator in the manner shown in Fig. 2. The arrangement presupposes special design features for the magneto and other means than the ordinary crank for starting the motor.

In a 12-horsepower Darracq the headlights are carried each in a fold of the sheet metal curtain of the fender, as indicated in Fig. 3, and the street lamps in the forward dip of the fender. Both headlights and lamps are of course electric.—From *La Vie Automobile*, June 6 and 13.

A French firm has conceived and executed the idea of turning out moldings for automobile bodies in ebonite, and Fig. 4 shows a variety of the shapes so far placed in the market. While ebonite is more expensive than wood as a material and its natural black lustre is suited mainly for carriages finished in black, it can easily be bent to almost any desired curvature when softened in warm water and will hold the shape given it; it requires no varnish and holds its finish without much caretaking.—From *Omnia*, May 16.

SAVING HIGH-SPEED STEEL—The Rosner method, developed in this country, for making high-speed tools by welding a tip of the expensive high-speed steel to a shank of ordinary mild steel, while accomplishing the hardening of the tip by the same operation as the welding, is favorably commented upon in *Werkstattstechnik* of June 1 and is credited with a saving of about 40 per cent over full-length tools of the costlier material. The advantage over short tools used with toolholders lies in a better radiation of heat through the shank and the better preservation of the cutting-edge which is the result. The high-speed tip, if long enough from the beginning, can be reforged and rehardened as if there were no weld.

Carbureter Throttled by Varying Area of the Venturi Port

IN most carbureters the narrowest place of the Venturi tube remains in the same place and is supposed to regulate the siphon action upon the gasoline in the jet. But when the throttle is closed so much that the sectional area which it leaves for the passage of the gas mixture is smaller than the sectional area of the Venturi channel around the jet, the location of the greatest suction is changed to the smaller area, and this, according to the idea of the designer of the Jann carbureter, causes disturbances in the continuity of the gas flow, which result in irregular and jerky accelerations.

The principle of the Jann carbureter, Fig. 5, is therefore that of throttling always at the same level around the jet, and this is done by substituting for the ordinary butterfly throttle a piston-like body with a succession of conical rings D which can be moved up and down concentrically with the jet. As the intervals between these cones and the central openings in them are graduated progressively, there corresponds to each position of the throttle: (1) a certain air section around the jet, determined by the size of the opening in the nearest higher cone, (2) a certain section for the passage of the gas mixture, determined by the sum of the circumferential openings of all the cones above the level of the jet, and (3) a certain orifice of the jet, determined by a needle *a* which moves up and down with the throttle body and enters more or less deeply into the bore of the jet.

In the extreme low position of the throttle-body, the sleeve K, surrounding the jet enters the central opening of the smallest diffuser-cone, almost blocking the passage of air, and this is the position for still-running.

The butterfly valve A noticed at the top of the device is not, according to the description, in itself a control member, but, being spring-connected with the throttle-body whose down-movement causes it to turn against the spring-resistance, it exerts a steadying influence and reduces the suction acting against the throttle-body, especially when this suction is at its maximum, in the position for still-running.

Other features of the Jann carbureter are the relatively capacious chamber J in the jet, which serves as a reservoir for accelerations, the calibrated bore *j* by which the carbureter is regulated to different motor sizes and the hot-air pipe H which can be removed if desired. [The description states that the sleeve K can be adjusted by means of a knurled nut, but the illustration does not show a construction rendering this feature possible.]—From *Omnia*, June 6.

Bonecourt Surface Combustion System with Liquid Fuel

WHILE the Bonecourt-Schnabel system for burning gas with a minimum of waste of the heat units contained in the fuel is of immediate interest mainly for economizing stationary steam engine practice and for use in mines and tunnels, where the very small amount of combustion gases from the flues and their coolness constitute features of great practical value, it continues to claim attention in wider circles on the strength of its scientific peculiarities which suggest that the principle may eventually be applied to small power plants for motor vehicles and in other now unforeseen directions. The combustion of gas, in the fire flues of a steam boiler on the Bonecourt system, was originally flameless and took place in the interior of a porous fireclay or chamot lining or filling of the tubes, but (as reported in THE AUTOMOBILE of May 21) practical difficulties led to modifications, after which the system can no longer be designated as strictly flameless, at least not so far as its development in Germany is concerned. *The Engineer* (London) now gives in its issues of May 15, 22 and 29 an account of the most recent experiments with the system in England, from which it appears that considerable headway has been made with the use of liquid and solid fuels, especially the former. The process employed is illustrated diagrammatically in Fig. 6 and consists in injecting the liquid fuel together with the amount of air required for its combustion into a chamber of small dimensions in which a partial gasification of the liquid takes place.

A fireclay sleeve in the front end of the boiler tube serves to conserve a certain amount of heat within the chamber thus formed. The chamber is closed at the same end by means of a fireclay plug, through an aperture in which the oil and air supplies are introduced. At its further end it is closed by a perforated septum, through which the gaseous products pass from the gasification chamber into the refractory packing in the boiler tube. Each boiler tube carries its own gasification chamber and porous refractory packing for the acceleration of the combustion. The dimensions marked on the diagram are those of a boiler erected at the London works of the Bonecourt company, and this boiler has been successfully fired for the past few months on the principle described, being in operation every day and supplying the works with power. The air required for the combustion is supplied by means of a fan developing a pressure of 35 inch water column, and the oil is fed to the tubes by gravity with a 12 foot head. Spraying of the oil in the gasification chamber is effected by the rapid flow of the air.

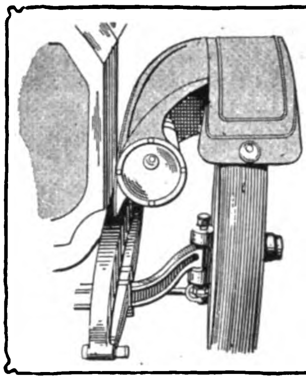

Fig. 3—Disposal of lamps

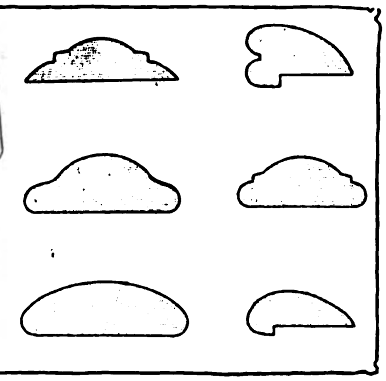

Fig. 4—Ebonite moldings

This boiler evaporates 25 pounds of water per square foot of heating surface per hour and, in doing so, utilizes 92.5 per cent. of the calorific value of the oil burned.

The nature of the refractory porous material naturally makes it difficult to apply the system, as it stands today, to boilers with fire tubes of the small dimensions which alone can be of interest from the automobile viewpoint; yet it is noticed that in another boiler which has been installed at the Bonecourt works the diameter of the tubes is reduced to 6 inches, and in the German experiments practically all the troubles arose from the presence of impurities, notably sulphur compounds in the gas used, which caused clogging of the porous material. As economy is at present the chief object in view in the development of the process, no data have as yet been offered based on the use of gasoline for fuel and small dimensions of the tubes and linings.

Rotary Pump and Hydraulic Transmission with Gear Wheels

THE working principle of a new rotary gear pump is indicated in Fig. 7. The mechanism consists of a rotatable elliptical spurwheel, an internally geared ring almost square in elevation and six circular spurgear pinions meshing between the ellipse and the square. As the ellipse is revolved, the space between any pair of the pinions increases from a minimum to a maximum and then decreases from the maximum to the minimum again. While each space is increasing it is in communication with a suction port, and while decreasing it communicates with a delivery port. The device is the invention of H. Dock of Westerly, Rhode Island, and can be used also as a hydraulic motor by letting the working fluid in at one set of ports and out at the other. A motor and pump combined have been constructed in the form of a hydraulic transmission with variable speed. For this

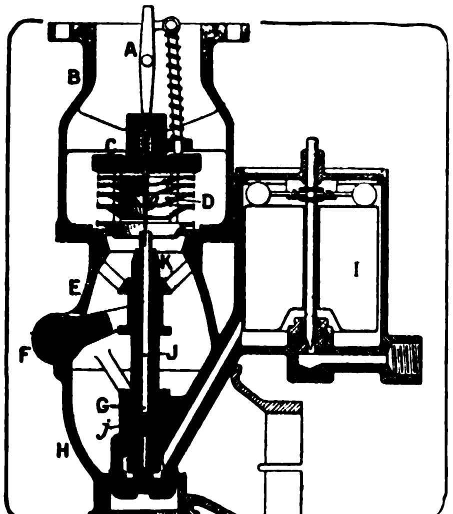

Fig. 5—Jann "Integrale" carbureter

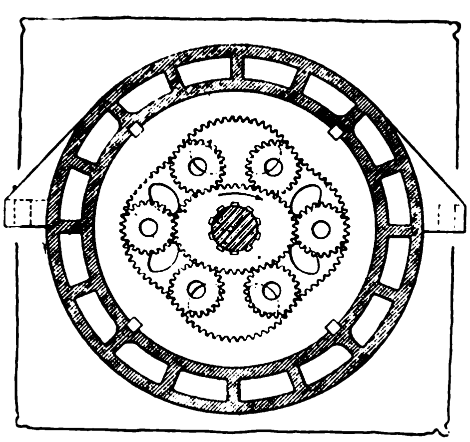

Fig. 7—Rotary pump and hydraulic gear

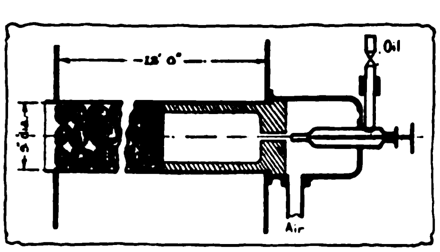

Fig. 6—Bonecourt system for liquid fuel

purpose the pump portion is in duplicate. The deliveries of the two pumps can be arranged to oppose each other or to assist each other to any desired extent up to the full maximum, by moving the relative positions of the internal and the elliptical gears of the two parts, and in this manner variations of the motor speed from zero to maximum is obtained in both directions.—From *The Engineer* (London), June 5, after *American Machinist.*

Number of Electric Vehicles Used in European Countries

ACCORDING to a private census taken in March of this year a considerable increase is noted in Europe in the use of electric vehicles for municipal utility purposes, and the distribution of the vehicles in the different countries is given as in the appended table. Sixty street sprinkling and flushing carts in use in Berlin, some of them since 1907, are said to have demonstrated a yearly saving of about $400 over the cost of the same work with horses as the motive power, and the use of electric tricycles for mail collections is being expanded yearly in Berlin, Vienna, Copenhagen and other large cities.—From *Allgemeine Automobil-Zeitung,* May 30.

Races for Improving the Springs of Ordinary Cars

ON THIS subject, now coming to the front, *The Motor* (London) writes substantially as follows: "There is one particular in which there is still much to learn and room for much improvement—the springing. The course over which the Tourist Trophy Race is to be held is not an easy one on springs at best, and it will certainly provide a good test at high speeds of both springs and tires. Naturally every entrant firm has taken the greatest care to make the springing of its cars as nearly perfect as may be, and various expedients in the nature of shock absorbers and rebound dampers will be universally resorted to; but, so far as we are aware at present, there is to be no radically new or different system of suspension tested, which is rather a matter for regret in view of the undoubted great scope for improvement in this direction. One has but to note the number of palliatives offered in the advertising pages of the motor journals to realize how far from perfection is the suspension of cars, and the use of such fittings on racing cars should provide valuable information for those who are in a position to obtain first-hand knowledge of how they operate in practice. Here again, though, racing and everyday conditions are at variance, and the lessons of racing cannot be applied to touring cars without the most careful consideration and weighing up of fancies and sorting out of facts."

[A contribution in the matter of answering the question, whether a spring suspension found superior for racing cars should also be suitable for ordinary driving speeds, is perhaps supplied through the tests made by Dr. Bobeth in Germany, who found that, so far as the two vehicles at his disposal were concerned, the worst oscillations of the chassis occurred at a speed of about 22 kilometers per hour. This result was of course due to the fact that at higher speeds the forward movement enters as a stronger factor to change the resultant of the forces due to spring action and gravitation and flattens out the trajectory described by the car body, so that its movements are felt in lesser degree as a succession of shocks. On the other hand, it apparently does not mean that the violence of the shocks absorbed in the springs was not greater at the higher speeds. Also, Dr. Bobeth's observation did not apply to shocks received from abnormally great road obstructions. Taking the two facts together, that high speed makes riding easier on a road of average roughness but increases the shocks which the springs must endure, there seems to be some good reason for believing that the spring requirements are sufficiently alike for high and medium speeds to make the results of racing experience in this respect almost directly applicable to ordinary cars.—ED.]

Russian Development of Aeroplanes Makes History

THOUGH the current technical details in the evolution of aviation lie beyond the scope of these columns, a note on the large lines of division which are becoming visible in this devêlopment in Europe may be of interest. So far the French monoplanes, according to Herbert Hinderscheidt, one of the engineers at the German aviation camp at Adlershof, have excelled in speed, reaching an average of 120 kilometers per hour, while German monoplanes of the very reliable but heavier "Taube" type do not get far beyond 90 kilometers. On the other hand, German biplanes have now been so perfected that their speed about equals that of the light French machines while their carrying capacity is much superior. During the Balkan war these biplanes proved themselves far more useful than the monoplane. But, after all, no great principle is involved in the relative merits of these types. It is the mammoth aeroplanes of the Russian army, designed by Sikorsky, that have taken the technical world by surprise. An entirely new type was here created, and the first machine showed wonderful results, despite the designer's lack of experience in building and operation. It worked much more economically than any previous aeroplane, left the ground at first trial and turned curves and spirals with perfect ease. Immediately thereafter Sikorsky, assisted by the government, built a second model which showed such qualities that the government at once ordered six more at a price of $500,000. This type is called the Ilija Murometz.

It has 4 motors of 100 horsepowers each and weighs 3,500 kilograms. At first trials it caried 15 persons and a payload of 1,300 kilograms. Its speed with this load was 100 kilometers per hour.—From *Der Motorwagen,* June 10.

SPOTWELDING IS NOT YET PRACTICAL, according to Otto Fuchs of Brünn, Austria, a specialist in welding and riveting, for uniting two metals of widely different fusion points; it is not yet developed for use with aluminum, though frequently good welds can be accomplished, and in practice autogenous welding is used for aluminum at the same factories where spotwelding is used for iron and steel. As an improvement on riveting, spotwelding is far more economical, speaking about sheet steel and iron, and gives greater average strength, but the results depend somewhat more on the ability and care of the workman.

The Cyclecar vs. the Light Car

Cyclecar Movement Not Absorbed by Light Car Activity—A Definite Field

By William B. Stout

THERE is a very much growing idea that the cyclecar movement is going to emerge as a light car enthusiasm, and that the cyclecar, so called, will thereby be a thing of the past.

This feeling is not without foundation, for those in touch with cyclecar developments see a great change coming over the whole movement, a reaction from the first burst of enthusiasm, which was predicted long before it came.

The idea of the cyclecar movement was to produce the cheapest possible motor vehicle, and it has been superseded because the cyclecar in its first forms has proved itself worthy of better constructions than had been given it at the start and because mechanisms of few parts have not proved as reliable nor as cheap to build and buy as more standard and more complicated parts.

Public Slow to Buy

Another point having a decided bearing has been the slowness with which the public accepted the cyclecar idea to the extent of actual buying. They enthused, they gathered in crowds to watch, they expressed enthusiasm, and they predicted wonderful things, but those who bought went to cars of automobile standards, and of those who enthused on cyclecars the most had little money to buy.

As a result, makers are taking to four-cylinder water-cooled motors, shaft drive and gearsets and live axle constructions. They are entering the light car field, with its sociable seating and its higher first cost and the public thinks the cyclecar movement has perhaps failed.

Cyclecar Movement Has Hardly Started

As a matter of fact the cyclecar movement has hardly started. Makers started to experiment with cyclecars and yet could not forget the automobile. They added this and they added that, and when all was done the cars weighed 800 pounds instead of the 450 they started out to reach, and this weight was to be driven by a motorcycle motor. The wonder was that motorcycle motors did handle this weight and are handling it to-day. The best of these V-motored cars are running satisfactorily, but only on those cars where there has been real workmanship. Some of them were so cheaply built that they did not last at all. These are the ones which have harmed the cyclecar movement and have set it back.

The cars produced were to sell at under $400, and did. They did not sell in the quantities expected, however, as when this price was paid the buyer wanted a motor car, and as light cars at this figure were produced at about the same time, the public bought the light car first. The cyclecar is still in embryo.

V Motors Cost Too Much to Build

A great reason for the change to four-cylinder plants was that the V motors available were too costly to build to enable their makers to make a price on them consistent with the performance. They were fast but they would not run slow; they had low fuel consumption and great noise, and the public was afraid of air cooling. All of this hindered sales, while in fact the motors were doing wonderful work. Only recently the writer drove a V-motor cyclecar on a straight stretch of concrete road near Detroit in a race with a car which was an exact duplicate except that it was fitted with a four-cylinder, much larger motor, and beat it easily. On a hill or in sand, however, the V motor would have been the loser, as it was pulling 950 pounds.

Cyclecars Should Weigh Under 500 Pounds

There is but one field for the cyclecar, and that is in the simple light class. The car should not weigh over 500 pounds, and should have a low gear ratio to the motor. This motor can be back of the rear seat and connected to the solid axle by a chain and motorcycle clutch on the motor shaft, without gearset. If there is a gearset it must be friction or its equivalent, light and very cheap; but exceptionally well built. The body should be very light, and be a single seater with perhaps a spare folding seat for a passenger when wanted. All of this must be on the basis of ultra simplicity and the selling cost must not be over $275, preferably to be paid on the installment plan. It would then appeal to a class between the motorcycle and light car and have a niche to fill.

To build this car certain things must be done, however. In the first place motors must be simplified. A V-type motor should be simpler than a four-cylinder, but at present they have more complication instead of less, due to the built-up crankshaft and the crankcase constructions. If the extreme of simplicity is sought the two-cycle motor should be thought of in the single-cylinder or two-cylinder type, as this is the cheapest of all to build and with friction drive should be flexible enough for a $250 car.

Simpler types of car are possible, and probable, and will have as wide a field of sale as the motorcycle and probably much wider.

Large Registrations in Indiana and Ohio

INDIANAPOLIS, IND., June 27—The Indiana Secretary of State is now issuing motor car licenses at the rate of 150 a day, and most of these are going to rural districts and small towns. There were 53,511 motor-car licenses issued from January 1 to June 15, inclusive. In 1913 there were about 45,000 licenses issued. Licenses on second-hand cars are being transferred at the rate of from ten to twelve a day.

According to a report issued by J. A. Shearer, state registrar of automobiles of Ohio there were 102,000 automobiles registered up to June 16. Chauffeurs to the number of 3,700 had been registered. Registrar Shearer estimates a registration of 115,000 automobiles, 25,000 motorcycles and 10,000 chauffeurs.

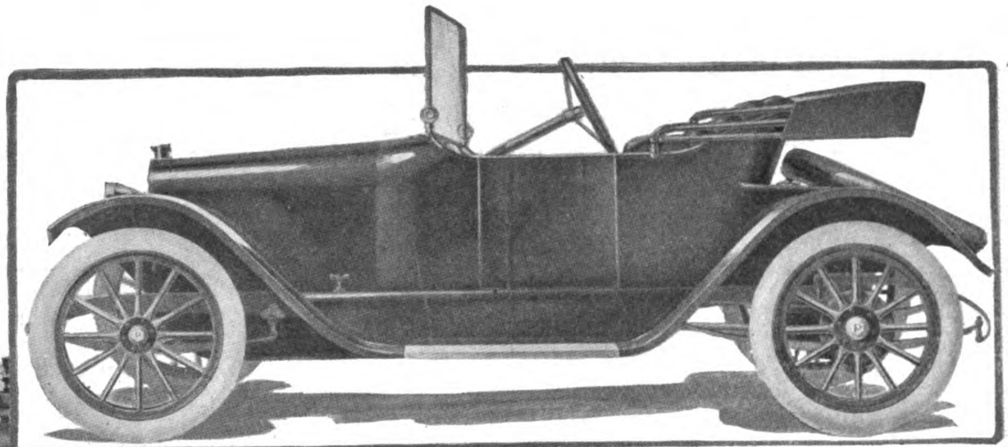
Iowa's 1914 Car Valuation, $115,000,000

DES MOINES, IA., June 27—Iowa will have $115,000,000 invested in automobiles at the close of the year 1914. This is the estimate of the state automobile department from figures compiled on the basis of registration to date. This will mean that the automobile wealth of the state will be just twice as great as it was in 1913. Over 86,000 automobiles already have been registered in Iowa this year. The entire registration for last year was only 65,000. Thus the number already registered for 1914 is 21,000 in excess of the total for 1913. State officials make a conservative estimate based on former years that the total registration for this year will be 115,000. If the average valuation is $1,000 the total value of all the cars in the state will be $115,000,000.

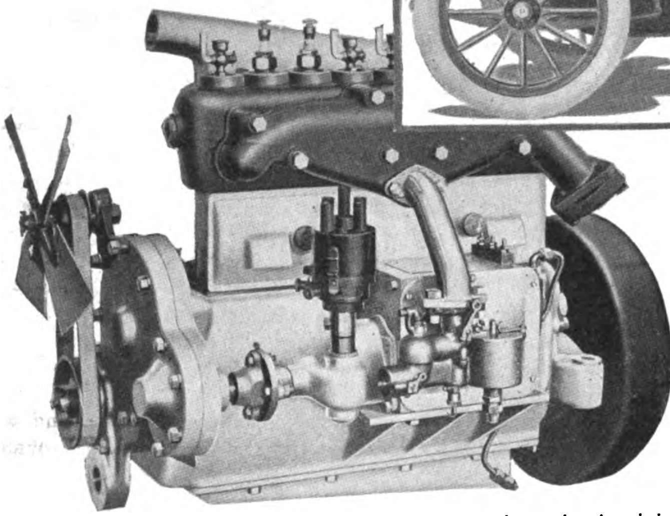
PONTIAC, MICH., June 27—J. Ward Robbins, formerly with the General Motors Co., of Detroit, and Pontiac, will open the first garage in Clarkson, Mich., this week. He will secure the agency for a medium price car.

$495 Partin-Palmer Has Generator

New Streamline Roadster Has Full Equipment, Three-Speed, Gearset and Self-Starter for $75 Extra



New Partin-Palmer two-passenger roadster



Right side of motor, showing generator, unisparker, simple piping and suspension arms

FOUR hundred and ninety-five dollars is the rather astonishingly low price of the new Partin-Palmer runabout with two-passenger body, considering that this figure includes a Gray & Davis lighting system, electric horn, windshield, top, tire case and tools. The car is equipped with a graceful streamline body, has a four-cylinder motor rated at 22 horsepower and it is stated that the machine will travel from 30 to 35 miles on a gallon of gasoline. It is to be known as model 20 and is designed for the 1915 season. It is made by the Partin Mfg. Co., Chicago, Ill.

Left drive and center control are used and another feature is the listing of a Gray & Davis self-starter at $75 additional. Double electric headlight bulbs, controlled from the cowl board are used and the tail light has a small electric bulb.

The motor is a clean-cut design with the four cylinders, which are of the L-head type, cast in a block. The bore is 2.75 inches and the stroke 4 inches. The intake and exhaust manifolds are, however, cast separately. The valves are inclosed and the piping is simple, which not only gives a neat looking motor but allows easy access to the valves. Three-point suspension is used, one point at the front and two at the rear.

Ignition is furnished by an Atwater Kent Unisparker that is supplied with current either from the generator or the storage battery. The Unisparker and generator are both located on the valve side of the motor and are driven from a single lay shaft. The shaft of the Unisparker is vertical and it is driven from the lay shaft by means of a pair of bevel gears.

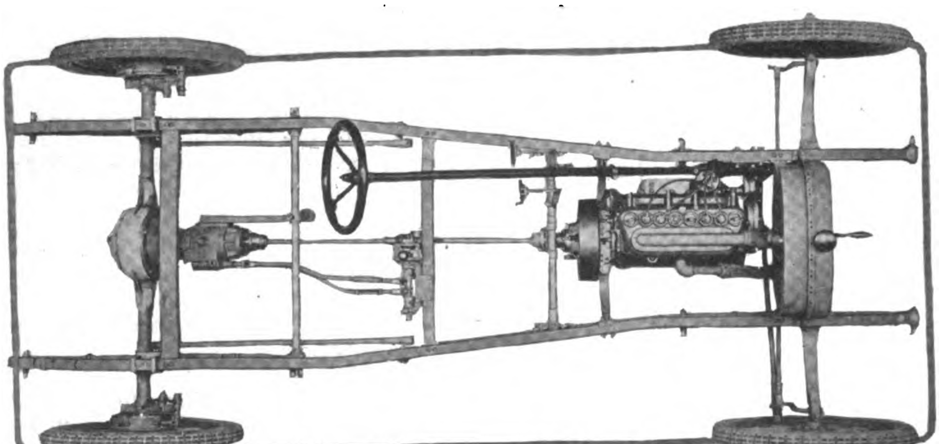
The crankcase is an aluminum casting and carries the crankshaft which is a drop-forging, made from heat treated carbon steel. The camshaft is also a drop forging, made in one piece. All reciprocating parts are carefully balanced to reduce vibration to the minimum.

Lubrication is by a combination splash system in which oil is provided by a plunger pump.

Cooling is effected by the use of a thermo-syphon system in connection with a honey-comb radiator and ball bearing belt driven fan.

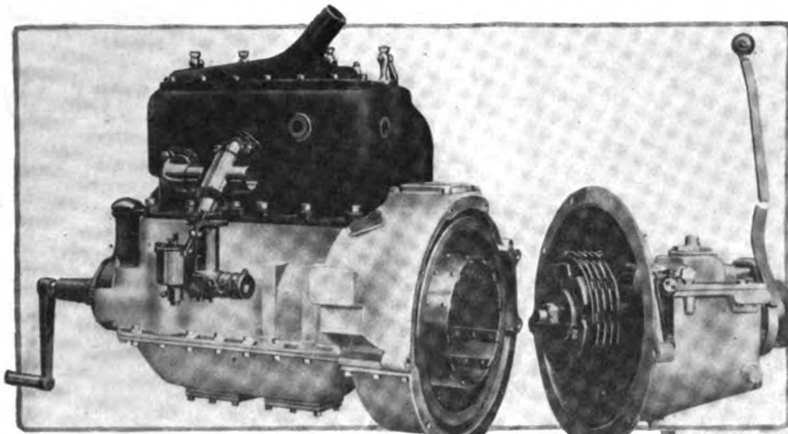
Drive from the motor is taken by a leather-faced cone clutch which is held in engagement by four coil springs. Access to the gearset on the back axle is readily had through removable side covers. Chrome nickel gears are employed and the shafts turn on annular ball bearings. An adjustment is provided for setting the driving pinion into proper mesh with the big bevel gear and there are adjusting nuts on the shifting rods.

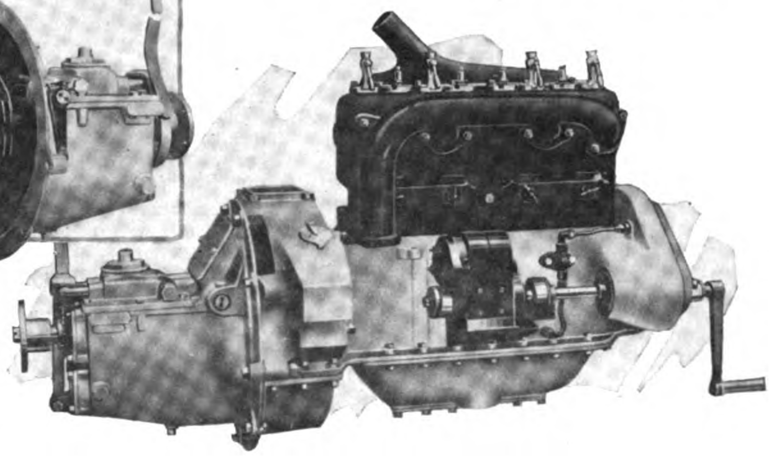
As already stated, the rear axle is a full-floating design the weight being carried entirely on the axle housing and the drive shafts merely turning the wheels. The drive shafts are made from nickel steel and heat treated. Annular ball bearings are supplied at the outer ends of the rear axle, while Hyatt rollers are used on either side of the differential. The end thrust is taken care of by ball bearings.



Plan view of chassis, showing suspension of motor, cone clutch and integral gearset and rear axle

Stewart Has Unit Power Plant





Intake side of motor used in new Stewart truck, showing unit power plant construction, center control and multiple disk clutch. At right, exhaust side

IN bringing out its 1915 model, 30-horsepower, 1500-pound delivery truck, the Stewart Motor Corp., Buffalo, N. Y., has simplified it in many ways, made it lighter yet stronger, and more economical to operate.

To begin with there are 500 less parts and by the use of refinements in the general motor and chassis design 25 per cent. more mileage for the same amount of gasoline and oil is obtained.

A unit power plant with three-point suspension is now used, this construction embracing a four-cylinder motor, inclosed disk clutch and sliding gearset. Left drive and center control are continued. The frame side members have been made perfectly straight so that their strength is a maximum and the fitting of the body is also facilitated by this change. Thermo-syphon cooling has been substituted for pump-circulation and fuel economy and increased power are the result of water-jacketing the intake manifold.

One other change is noted in the cooling system. Last year the circulation of air through the radiator, which is mounted on the dash, was aided by fan spokes in the flywheel, but suction is now produced by a belt-driven fan. A glass windshield has been added to the regular equipment, thus not only giving protection to the driver, but adding to the appearance of the car. Aluminum panels have displaced wood in the body construction. A Westinghouse electric starting and lighting outfit is furnished as extra equipment.

A feature of the new truck is that all important units are quickly and easily removable.

Only one chassis model is manufactured, but it is equipped with many styles of bodies. The price of the chassis is $1,500 and the bodies are extra, varying from $125 to $850.

The motor is a Continental with the cylinders cast in a block and the valves are on the right side. The bore is 3.5 inches and the stroke 5 inches, and it is rated at 30 horsepower. The exhaust manifold is separate and has individual passages leading from the four cylinders. The carbureter is a Zenith and is situated on the left side of the motor, the intake passage being cored through the cylinder casting.

The oiling system is a force-feed, constant-level type. A plunger pump operated by an eccentric cam on the camshaft forces the oil to the various motor parts. Ignition is supplied by a Bosch DU4-2 situated on the valve side of the motor.

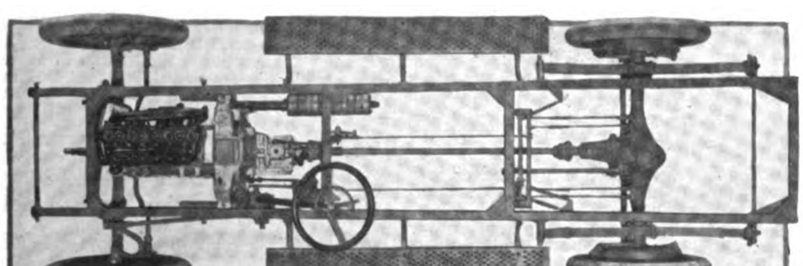
The clutch is a dry plate, multiple-disk type, contained in the flywheel, with one set of steel plates and another set of Raybestos-lined steel plates. There are nine plates in all and the surface is 230 square inches.

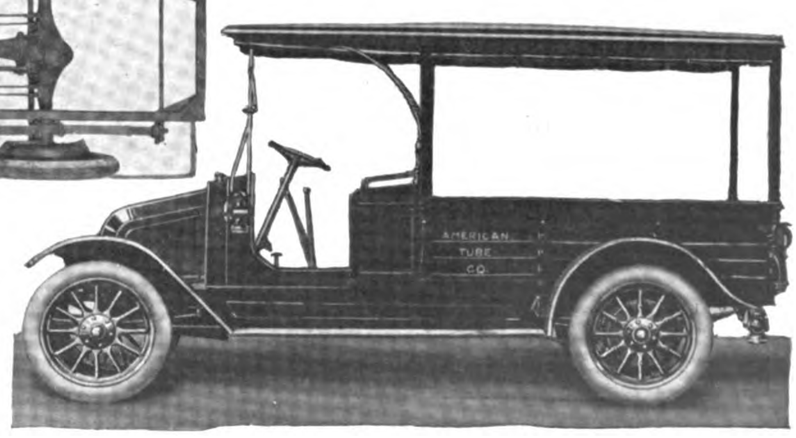
The gearset is a sliding type, affording three speeds forward and one reverse. It bolts directly to the bell-shaped housing that incloses the flywheel and clutch.

There are two universals in the drive shaft and the rear axle is a floating construction of Timken make. The gear ratio is 5.5 to 1. The front axle is also of Timken design.

The steering gear is a worm and sector which permits of bringing a new quarter of the worm wheel in contact with the worm when it becomes worn. A feature of the steering mechanism is a ratchet control on the steering post to prevent slipping due to road shocks and vibrations.

Semi-elliptic springs are used front and rear, and 34 by 4.5-inch pneumatics fitted with Firestone quick-detachable, demountable rims are standard. An extra rim with a carrier is included and also a tool kit, tire pump, jack and repair outfit.





Above—Plan view of chassis used in new Stewart truck, showing unit power plant, left drive and center control and simple construction. The new truck is said to have 500 less parts than the old model. At the right is shown the truck fitted with an open express body. Note housing of radiator in extension of dash cowl

Factory Miscellany

NEW Million-Dollar Factory—Work has begun on the $1,000,000 plant on Thomson avenue, Long Island City, for the American Ever Ready Co., a branch of the National Carbon Co., Cleveland, O., and it is expected to have the building completed and ready for occupancy by February, 1915. The structure will be 200 feet by 300 feet, and eight stories in height. It will be of reinforced concrete throughout with concrete floors, metal doors and window frames and will have over 500,000 square feet of floor space. The plant will give employment to 2,000 persons. The company's output of batteries, lamps, flashlights, speedometers, automobile starters and other automobile supplies amounts to about $5,000,000 per year. The company's plot, which is on the Degnon Terminal Co.'s improvement tract, occupies an entire block, 600 feet front on each Manley and Orton streets and 200 feet on Thomson avenue and Manley street. It is expected the plant will before many years be enlarged to take in the entire block. The plant at Long Island City will be made a distributing center as well as a main factory for the company's goods.

Auto Body Co. Adds—The plant of the Auto Body Co., Lansing, Mich., will be enlarged, permission having been granted for the erection of a three-story brick building.

Blood Bros. Will Enlarge—The plant of the Blood Bros. Machine Co., of Kalamazoo, Mich., will be enlarged, the addition to be used as the assembling plant for the cyclecars which the concern is now making.

Three Crescent Cars Built—The Crescent Motor Car Co., St. Louis, Mo., who about six months ago opened a factory there, has three stock cars ready for delivery. The name of the car has been changed from Crescent to Superior.

American Metal Products Co. Working—The American Metal Products Co., Milwaukee, Wis., organized recently to engage in the manufacture of bronze die castings, has started operations in part of the brass foundry of the defunct Wambold Mfg. Co.

Detroit Tire Plant in Springfield—The Detroit Pneumatic Tire Co. has been organized in Detroit, Mich., and will manufacture tires. The plant is now being erected in Springfield, Ill., but headquarters are for the time being at 915 Ford Bldg., Detroit.

Will Manufacture Rims—The Lookout Bending Co., Chattanooga, Tenn., recently organized, will soon be ready to commence operations near Sulphur Springs, Ga. The factory is now being erected in which automobile wheel rims and spokes will be manufactured. F. S. Baumgartner is president.

216,056 Goodyear Tires in April—During the month of April the Goodyear Tire & Rubber Co., Akron, O., produced a total of 216,056 pneumatic tires. Of this number 186,491 were automobile tires and 29,565 were motorcycle tires. The total number of automobile tires for the fiscal year, to the first of May, was 699,342.

Baltimore Co. Will Move—The Baltimore Hub, Wheel & Manufacturing Co., Baltimore, Md., has leased the Hitchens storage warehouse at Saratoga and Holliday streets, to which it will remove its factory for carriage, wagon and automobile wheels from its present location on Harford avenue, which it sold to the McShane Bell Foundry Co.

Miller Rubber's New Factory—The Miller Rubber Co., in Akron, O., has purchased the factory of the Frantz Body Co., which is located just to the north of the present factory. It is the plan to tear down the old buildings and erect a modern fireproof factory building. It is planned to build a new warehouse in the rear of the present factory building also.

Will Manufacture Springs—Springs for automobiles and other vehicles will be made by the Pallau Steel Co., which has been organized in Mt. Clemens, Mich., with a capital stock of $75,000, of which $60,000 has been subscribed. A. T. Donaldson is president of the new concern; A. J. Pallau, vice-president, and Clifton D. Jackson, secretary-treasurer. Mr. Pallau was during many years an official of the Detroit Steel Products Co.

Continues Ford Belt Manufacture—The C. & B. Hinson Co., Liddell and Grove streets, Cincinnati, O., has recently been purchased by E. P. and M. A. Zachman, who will continue to operate the company under its old firm name of the C. & B. Hinson Co. at 2717-2719 Webster avenue. The above parties will continue to specialize in Ford endless fan belts, which are made of linen and cotton fabric tape, put together by special machinery. They have equipped their factory with machinery that will enable them to not only make a four-ply but also a five-ply belt.

The Automobile Calendar

July 2, 3, 4.......Denver, Colo., 270-Mile Consistency Race.
July 3-4.........Tacoma, Wash., Montamara Festo Races, Tacoma Speedway Assn.
July 3-5.........Denver, Colo., All-Colorado Auto Derby. Denver Motor Club.
July 4...........Utica, N. Y., Hill Climb, Auto Club of Utica.
July 4...........Visalia, Cal., 150-Mile Road Race.
July 4...........Prescott, Ariz., Road Race, Prescott Auto Club.
July 4...........Sioux City, Iowa, 300-Mile Race, Sioux City Auto Club and Speedway Assn.
July 4...........Lyons, France, French Grand Prix.
July 4-5.........Chicago, Ill., Track Meet, Hawthorne Track.
July 13-14.......Seattle, Wash., Track Races, Seattle Speedway Assn.
July 25-26.......Belgium Grand Prix Road Races.
July-August.....French Army Truck Subsidy Trials.
Aug. 1-3.........Galveston, Tex., Beach Races.
Aug. 2-9.........Grenoble, Automobile Club of France's 6-Day Motorcycle and Cyclecar Reliability Contest in French Alps.
Aug. 16..........Le Mans, France, Automobile Club de la Sarthe's Coupé International Light-Car Race, 1 liter, 400 maximum cylinder area, 350-500 kilos weight.
Aug. 17..........Le Mans, France, Auto Club de la Sarthe's Grand Prize de France for 4½ liter cars.
Aug. 21-22.......Chicago, Ill., Elgin Road Races, Chicago Automobile Club.
Aug. 23..........Auvergne, France, Coupé de l'Auto Race.
Aug. 27..........Brooklands Track, England; Annual Automobile Race.
Aug. ....Denver, Colo., 650-mile Run, Colorado Springs to Salt Lake City.
Aug. ....Russia, Road Race, Coupe de l'Empereur, 2,500 miles.
Sept. 6-7.........Brescia, Italy, Auto Club of Italy's 4½-liter Grand Prize.
Sept. 6-7-8.......Newark, N. J., Cyclecar Reliability Tour to Atlantic City.
Sept. 7-14........Indianapolis, Ind., Automobile Show, Indianapolis Automobile Trade Assn.
Sept. 9..........Corona, Cal., Road Race, Corona Auto Assn.
Sept. 10.........Portsmouth, Eng., Autumn Conference, Institute of Metals.
Sept. 10-15.......Berlin, Germany, German 4½-liter race.
Sept. 15-Oct. 11..New York City, Commercial Tercentenary Celebration.
Sept. 26.........Brooklands Track, England, Annual Automobile Race.
Sept. 26-Oct. 6...Berlin, Germany, Automobile Show.
Oct..............Philadelphia, Pa., E. V. A. A. Annual Convention.
Oct. 7-17........New York City Electric Vehicle Show, Grand Central Palace.
Oct. 9-Nov. 2....S. A. E. European Trip.
Oct. 16-26........Paris, France, Automobile Salon.
Oct. 17-24.......Pittsburgh, Pa., Automobile Show, Auto Dealers Assn., Inc.
Oct. 19, 20, 21....Philadelphia, Pa., Elec. Veh. Assn's Convention.
Oct. 19-26........Atlanta, Ga., American Road Congress of the American Highway Assn. and the A. A. A.
Oct. 28-31........Milwaukee, Wis., Convention, Northwestern Road Congress, Auditorium.
November ....El Paso, Tex., Phoenix Road Race, El Paso Auto Club.
Nov. 6-14........London, England; Olympia Show.
Nov. 8-9.........El Paso to Phoenix, Ariz., Automobile Race.
November 8-11..Shreveport, La., Track Meet, Shreveport Auto Club.
November 15.....Paris, France, Kerosene Motor Competition.
Jan. 2-9.........New York City, Annual Automobile Show, Grand Central Palace.
Jan. 23-30.......Chicago, Ill., Automobile Show, First Regiment Armory.

The Week in  the Industry

Motor Men in New Roles

MILLHOFF General Sales Manager—F. C. Millhoff, formerly tire sales manager of the Miller Rubber Co., Akron, O., has been appointed general sales manager.

Lynch General Manager—Leigh Lynch has become general manager of the American Top Co., Jackson, Mich., and Tilbury, Mich.

Booth with Universal Truck—N. Booth, formerly general manager of the Studebaker Corp., Detroit, Mich., is now with the Universal Motor Truck Co., Detroit.

Roark Appointed District Manager—J. F. Roark, formerly with the Cole concern, has been assigned as district manager of the St. Louis, Mo., district for Dodge Bros., of Detroit.

Spencer Gets Promotion—J. E. Spencer, of the Studebaker Corp., has been appointed assistant to First Vice-President A. R. Erskine, of the Studebaker concern, with headquarters in Detroit, Mich.

Willis Leaves National—P. P. Willis has resigned as advertising manager of the National Motor Vehicle Co., Indianapolis, Ind. He became a member of the advertising firm of Thompson-Carroll-Tripp of Cleveland July 1.

Arbogast Cole Manager—E. E. Arbogast has been appointed manager of the Cole Motor Co. of Missouri, St. Louis, to succeed Nelson W. Gotshall, resigned to take active charge of other personal interests. Mr. Arbogast formerly was connected with the Cole company at Indianapolis in both engineering and sales capacity.

Wagner with Century Electric—E. Wagner, an old-timer in the electric vehicle trade, has become associated with the Century Electric Co., of Detroit. He will direct his efforts in building up the efficiency of the sales and service branches in the national field and will organize a department for assisting dealers.

Clifford Sails July 8—J. E. Clifford, for the past 2 years representative of the General Motors Export Co. at the Buick factory at Flint, Mich., will sail from Vancouver July 8 on the steamer "Makura" for Sydney, Australia, to take general management for Australia and New Zealand. Buick business in this territory last year was about 1,000 cars.

Buffalo Electric's New Appointments—W. A. Zimmerman, formerly secretary and general manager of the Mercury Mfg. Co., has been made director of sales and publicity for the Buffalo Electric Vehicle Co., Buffalo, N. Y. F. C. Brown, formerly district manager for the Chase Motor Truck Co., has been made sales manager of the truck department of the same company.

Leaves for International Rubber Congress—Dr. K. J. Thompson, chief chemist of the Federal Rubber Mfg. Co.'s laboratories at Cudahy, Wis., recently left for Europe to attend the rubber auctions in Liverpool, Antwerp, Hamburg and London, also to attend the International Rubber Exhibition and Congress to be held in London June 24 to July 9.

Kiesewetter Houk Advertising Manager—The Geo. W. Houk Co., Buffalo, N. Y., announces the appointment of H. M. Kiesewetter, formerly of the Michelin Tire Co., as advertising manager and manager of its New York branch, located at the northeast corner of Fifty-eighth street and Broadway, from which office all Houk wire wheel business in Greater New York is being handled.

Jarrard on Western Trip—T. E. Jarrard, vice-president of Apperson Bros. Auto Co., Kokomo, Ind., is engaged in an extensive business trip through the West, visiting the largest distributers west of the Mississippi River. His desk at the main offices in Kokomo is being occupied by W. Carl Parker, of the Chicago branch. James Apperson, traveling representative of the company in the Great Lakes district, has assumed Mr. Parker's regular duties in the meantime.

Johnson Remy's Foreign Representative—The Remy Electric Co., Anderson, Ind., has closed negotiations with W. H. Johnson, 60 Haymarket, London, England, who will represent the Remy company in the capacity of manufacturer's agent in Europe. Mr. Johnson will also open a completely equipped service station to take care of all users and dealers of Remy products on the Continent.

Henderson Leaves Baker Co.—O. B. Henderson, sales manager of the pleasure car department of the Baker Motor Vehicle Co., Cleveland, O., on account of personal interests on the Pacific Coast which demand his constant attention will sever his connection with this company. Mr. Henderson leaves the latter part of this month to take up his permanent residence in Los Angeles.

Garage and Dealers' Field

King Co. Entertains Manufacturers—The King Motor Car Co., Detroit, is entertaining during two days at its cottages at Lake Orion, Mich., seventy parts manufacturers and other officials of the King company.

American Distributing Co. Moves—The headquarters of the American Distributing Co., general sales agent for automobile parts manufacturers, have been removed from Jackson, Mich., to the Goldberg Building, Woodward avenue, Detroit.

Bids on Richard Plant Opened—Bids will be opened soon by the Richard Automobile Co., Cleveland, O., for the erection of a large plant just off Broadway near the belt line railroad. The structure will be almost completely enclosed with glass. It is planned to have the plant completed in 3 months.

Michigan Building at Exposition—The Reo Motor Co., Lansing, Mich.; the Paige-Detroit Motor Co., the Fisher Body Co. and the Metal Products Co., all of Detroit, have each contributed $250 toward the fund for the construction of a Michigan building at the Panama exposition. These were the first large contributions received for the purpose.

Montreal's Record Shipment—What is believed to be the record for the number of automobiles taken on a single ship from Montreal will be exported on the Anglo-Egyptian steamer of the New Zealand Shipping Company when she cleared from Montreal on June 20. She took no less than 400 cars, including both runabouts and touring machines.

New Ford Service Bldg.—The Ford Motor Co., of Canada, Ltd., will build a general service building which is now in the course of construction in Montreal, Que. The building is of concrete construction, four stories in height, occupying a lot approximately 160 feet square, which would give a floor space of something over 100,000 square feet. It is expected that it will occupy the new building about the first of October.

Service Station to Be Opened—The Twombly Car Corp. is about to convert its four-floor experimental laboratory, which it has maintained at 258 West Sixty-ninth street for several years, into a service station. The experimental laboratory will be moved to the new Twombly factory at Nutley, N. J., at an early date. This laboratory is solely devoted to the inventing and testing of improvements for Twombly cars.

Westinghouse System on Dorris—The Westinghouse Electric & Manufacturing Co. announces that the Dorris Motor Car Co., St. Louis, Mo., has adopted the Westinghouse electric equipment for starting, lighting and ignition on 1915 cars. This equipment consists of a combination ignition and lighting generator together with a complete complement of switches, fuse boxes, junction boxes, and starting motor with switch and ammeter.

Co-operative Motor Delivery—Merchants of Waukesha, Wis., have decided to give a co-operative motor delivery system a 60-day trial. Charles Hamm, a dealer at Waukesha, who operates a motor truck line, is behind the scheme and has assured the merchants that he can effect a saving of 20 per cent. in their delivery costs. A central distributing station will be established and three deliveries will be made in the morning and two in the afternoon. This will be the first attempt in any Wisconsin city to test the merits of the co-operative system.

Oldsmobile Agent's Three Branch Stores—C. H. Larson, New York City, dealer in Oldsmobiles, has ordered a large number of the small four-cylinder cars from the factory, and in order to sell them he has hit on a plan new to Automobile Row. This is to establish three temporary showrooms in addition to his own in West Fifty-eighth street, where sample cars may be seen and where orders may be taken. One store is at the southwest corner of Fifty-seventh street and Broadway. Another is in the Hudson Terminal Building and the third is to be on a busy and prominent corner in the Bronx.

Recent Incorporations in the Automobile Field

AUTOMOBILES AND PARTS

BOSTON, MASS.—L. M. Cotton; capital, $50,000; to deal in automobiles. Incorporators: F. E. Crowford, A. M. Cussen.

BOSTON, MASS.—Motor Economy Co.; capital, $10,000; to deal in automobile supplies. Incorporators: Philip K. Farrington, Newton, John W. Smith.

BROOKLYN, N. Y.—John P. Agnew; capital, $5,000; to deal in automobiles and supplies. Incorporators: Robert B. Agnew, John P. Agnew, Annie T. Maude.

CHATTANOOGA, TENN. — Forstner-Shackelford Co.; capital, $5,000; automobiles. Incorporators: Ernest W. Forstner, Chas. C. Shackelford, Chas. A. Ryerson.

CHICAGO, ILL.—Danielson Engine Works; capital, $50,000; to manufacture automobile parts and accessories. Incorporators: F. Danielson, E. T. Runyan, R. Williams.

CHICAGO, ILL.—Duryea Motor Sales Co.; capital, $100,000; automobiles. Incorporators: A. P. Cambell, V. H. Stackwell, J. E. Packer.

CHICAGO, ILL.—Flex-Spring Co.; capital, $5,000; to manufacture automobiles and sell automobile parts and accessories. Incorporators: Thomas R. Beman, Albert F. Mecklenburger, Ward B. Sawyer.

CHICAGO, ILL.—R. H. Lyon Co.; capital, $2,500; to deal in and repair automobiles. Incorporators: Franc D. Mayer, Selma G. Mayer, Walter Herschman.

CLEVELAND, O.—Jiffy Jack Co.; capital, $50,000; to manufacture and sell automobile parts and accessories. Incorporators: J. P. Engle, E. K. Harpster, M. F. Thompson, E. A. Edwards, N. B. Wildman.

CLEVELAND, O.—Packard Cleveland Motor Co.; capital, $40,000; to deal in automobiles. Incorporators: J. L. Cannon, C. W. Fuller, W. A. McIlrath, H. E. Werner, E. E. Linden.

COLUMBUS, O.—Swarts Carbureter Co.; capital, $50,000. Incorporators: M. A. Corbett and others.

INDIANAPOLIS, IND.—Comet Cyclecar Co.; capital, $20,000; to manufacture and sell cyclecars. Incorporators: F. P. Mertz, L. F. Mertz, W. H. Ogborn.

GREENSBORO, N. C.—R. G. Sloan Motor Co.; capital, $25,000; to deal in automobiles. Incorporators: R. G. Glenn, F. P. Hobgood, R. G. Sloan.

HAMILTON, ONT.—Wentworth Motors, Ltd., capital, $40,000; to manufacture motor cars and trucks. Incorporators: D. B. Wood, C. W. Heming.

HARTFORD, CONN.—Greenlief Mfg. Co.; capital, $35,000; to manufacture automobile parts. Incorporators: George J. Long, W. H. Greenlief, John R. Hays.

HUBBARD, O.—Hubbard Auto Repair Co.; capital, $2,000; to deal in and repair automobiles. Incorporators: S. D. L. Jackson, H. T. McCarthy, A. H. Howatt, N. S. Logan, J. Boshin.

INDIANAPOLIS, IND.—American Underslung Co.; capital, $50,000; to manufacture and deal in automobiles. Incorporators: O. M. Brown, A. W. Ogborn, E. Duncan.

NEWARK, N. J.—Boaræm-Nicholas Motorcar Co.; capital, $100,000; to deal in automobiles. Incorporators: R. R. Boaræm, Louis B. Thedand, J. Dykers Nichols.

NEW YORK CITY—Cook & MacConnell; capital, $1,500; automobiles. Incorporators: John MacConnell, Eugene T. Scudder, Benj. N. Scudder.

NEW YORK CITY—J. & P. Sales Co.; capital, $5,000; to manufacture motors. Incorporators: Jos. J. Miller, Walter L. Perley, Grace Feeney.

NEW YORK CITY—Physicians Automobile Co.; capital, $70,000. Incorporators: Geo. Maschke, Milton Elkan, Harry Elkan.

NEW YORK CITY—Meder-Staudt Co.; capital, $10,000; to manufacture and deal in engines, motors, etc. Incorporators: Philip F. Meder, Charles Meder, Charles Staudt.

NEW YORK CITY—William Woop Co.; capital, $25,000; to manufacture auto bodies, etc. Incorporators: Fernando Woop, Maurice A. O'Connell, Glenn M. Congdon.

NINEVAH, N. Y.—Ninevah Coach and Car Co.; capital, $15,000. Incorporators: George B. Raymond, Wm. A. Hyer, Frank L. Horton.

ORANGE, N. J.—Coppinger Motorcar Co.; capital, $5,000; to deal in automobiles. Incorporators: F. W. Coppinger, J. R. Monroe, Harry G. Dechant.

PERTH AMBOY, N. J.—New Era Auto Co.; capital, $50,000; automobiles. Incorporators: Alexander Conquest, Richard Henderson, Thomas Conquest, Perth Amboy.

RIPLEY, N. Y.—Burrows Cyclecar Co.; capital, $30,000; to manufacture cyclecars and novelties. Incorporators: J. W. Burrows, R. P. Burrows, Robert Burrows.

ROSSLYN, VA.—Carter Car Sales Co.; capital, $15,000; to deal in automobiles. Incorporators: Oscar A. Reed, W. C. Balderson.

SARANAC LAKE, N. Y.—Gray-Bellows Motor Co.; capital, $5,000. Incorporators: Earl L. Gray, Elbert E. Bellows, Fred T. Tremble.

ST. LOUIS, MO.—Car-Nation Motor Car Co.; capital, $10,000; to deal in automobiles and accessories. Incorporators: Odon Guitar, Frank B. Ottofy, Robert L. Guthrie.

ST. LOUIS, MO.—Champion Motor Car Co.; capital, $50,000; automobiles. Incorporators: A. R. Walton, O. A. Peters, F. D. McMahon.

ST. LOUIS, MO.—Vesper-Buick Auto Co.; capital, $50,000; automobiles. Incorporators: F. W. A. Vesper, Fred Campbell, F. E. A. Brock.

TORONTO, ONT.—Kel-Kee Cyclecar Co.; capital, $40,000; to manufacture power propelled vehicles, etc. Incorporators: J. J. MacLennan, J. N. Black, A. Adams.

WILMINGTON, DEL.—Cycle Car Co.; capital, $100,000; to deal in cyclecars.

GARAGES AND ACCESSORIES

BOSTON, MASS.—Motor Economy Co.; capital, $10,000; to deal in automobile supplies. Incorporators: Philip K. Farrington, John W. Smith.

BROOKLYN, N. Y.—Miller & Van Winkee; capital, $150,000; to manufacture metal springs and auto accessories. Incorporators: Clarence Miller, Edward M. Miller, Gilbert P. Brush.

BROOKLYN, N. Y.—Spencer Garage; capital, $5,000. Incorporators: James O. Spencer, Jr., Anne E. Spencer, Paul M. Weldmann.

BROOKLYN, N. Y.—Standard Garage; capital, $10,000. Incorporators: Domenico Saladino, August Quick, Auguste M. Quick.

BUFFALO, N. Y.—M. & M. Delivery & Garage Co.; capital, $20,000. Incorporators: George Roughhead, Reynold MacDonald, Maud MacDonald.

CHICAGO, ILL.—Alladin Electric Co.; capital, $10,000; to deal in electric and automobile merchandise, supplies, etc. Incorporators: Samuel P. Marmly, Jr., Norman C. Croshaw, Joseph Bonomo.

CLEVELAND, O.—Jiffy Jack Co.; capital, $50,000; to manufacture automobile accessories. Incorporators: J. P. Engle and others.

COLUMBUS, O.—Hubbard Auto Repair Co.; capital, $2,000; to deal in auto repairs. Incorporators: S. D. L. Jackson, H. T. McCarthy, A. H. Howatt, E. S. Logan, J. Boshim.

COLUMBUS, O.—Swartz Carbureter Co.; capital, $50,000; to make automobile accessories. Incorporators: E. A. Corbett, F. E. Stevens, R. J. Corbett, T. A. Swartz, L. S. Corbett.

DETROIT, MICH.—Johnson Co.; capital, $30,000; to manufacture automobile accessories. Incorporators: Walter R. Johnson, Chester T. Johnson, Irvin Long.

ELYRIA, O.—Cook Taxicab Co.; capital, $2,000; general taxi business. Incorporators: C. B. Cook, H. W. Ingersoll, F. N. Stetson, F. Vandermark, Frank Beebe.

E. ORANGE, N. J.—Reiss Starter Co.; capital, $200,000; to manufacture automobile starters. Incorporators: Charles Reiss, W. B. Riley, A. G. Causland.

JERSEY CITY, N. J.—Mutual Oil Co.; capital, $125,000; to deal in oils and other supplies for motor vehicles. Incorporator: E. B. Ryder.

JERSEY CITY, N. J.—Pell-Mello Horn Co.; capital, $3,000; to deal in automobile accessories. Incorporators: W. S. Myers, Helen Myers, F. T. Wentworth.

MOUNT VERNON, N. Y.—Jacob Norden Inc.; capital, $10,000; to deal in auto supplies, etc. Incorporators: Max Jaeger, Jacob Norden, Sarah J. Forden.

NEWARK, N. J.—Washington Park Garage Co.; capital, $125,000. Incorporators: Gussie Devine, Arthur Devine, Jr., Paul F. Devine.

NEW YORK CITY—Anthony Benofrio & Co.; capital, $2,000; taxicab and garage business. Incorporators: Giovanina Benofrio, Anthony Benofrio, Jr., Antonio DeFio.

NEW YORK CITY—Equitable Garage; capital, $1,000. Incorporators: Harry Thal, Elizabeth Selnick, Henry Selnick.

NEW ORLEANS, LA.—Acme Automobile Co.; capital, $18,000; to deal in and repair automobiles.

NEW YORK CITY—Motor Gasket Co.; capital, $10,000; to manufacture motor gaskets, auto accessories. Incorporators: Clarence H. Loewenthal, Paul H. Loewenthal, Ralph M. Loewenthal.

NEW YORK CITY—National Auto Repair Co.; capital, $3,000. Incorporators: Edw. N. Grossman, Albert F. Tins, Walter Peppin.

NEW YORK CITY—Safety Taxicab Co.; capital, $1,000. Incorporators: Francis W. Russell, Grace U. Una, Francis Rosenblum.

NEW YORK CITY—Spartan Tire and Rubber Co.; capital, $100,000; to deal in automobile tires. Incorporators: H. L. Graffe, H. Feuchwanger.

PONKA, OKLA.—Ponca City Garage; capital, $10,000. Incorporators: W. H. McFadden, J. B. Hinkle, B. L. Hobbs.

ROCHESTER, N. Y.—Independence Tire & Rubber Co.; capital, $5,000. Incorporators: L. Walter Lissberger, Henry L. Lewis, Frank H. Gross.

ROCHESTER, N. Y.—Fox Taxicab Co.; capital, $6,000. Incorporators: P. Rothenbuescher, C. F. Buehlte, J. T. Fox.

SEATTLE, WASH.—Pacific Rubber & Tire Mfg. Co.; capital, $25,000; to manufacture automobile tires and tubes. Incorporators: B. L. Gates, C. A. Kilbourne and others.

ST. LOUIS, MO.—Airplex Inner Tire Co.; capital, $3,000; to deal in automobile tires, etc. Incorporators: Richard M. Howe, James H. Howe, Stanton Palmer.

YOUNGSTOWN, O.—Auto Gas Service Co.; capital, $10,000; to deal in automobile supplies. Incorporators: J. P. McCombs, S. A. Daniels, W. R. Ludt, M. J. Daniels, A. K. Len.

CHANGE OF NAME AND CAPITAL

CHICAGO, ILL.—Motor Devices Co.; increase of capital from $3,000 to $25,000.

JACKSON, MICH.—E-C Clark Motor Co.; capital increased from $15,000 to $265,000.

JACKSON, MICH.—Lewis Spring & Axle Co.; capital increased from $350,000 to $750,000.

TOLEDO, O.—Universal Machine Co.; capital increased from $125,000 to $200,000.

Accessories for the Automobilist

Mayo Electric Garage Pump—The Mayo Mfg. Co., Chicago, has put on the market a new design of electric garage pump, Fig. 1. The equipment consists of a two-cylinder pump, driven by .25-horsepower electric motor through silent chain drive. The pump is kept cool by a constant flow of water around the water-jacketed cylinder supplied from the water tank located over the electric motor. To eliminate any chance of burning out the electric motor by starting against too heavy a resistance an auxiliary tank is located under the pump. This is fitted with a check valve outlet with a hose which connects with the tire valve. It also is fitted with a pet cock which opens automatically when the starting switch is turned off. Consequently the motor is always started up against the pressure of the empty tank, permitting it to speed up before it encounters the heavy tire pressures. The outfit is mounted on a heavy oak base fitted with castors and the long handle is required for moving it about. Ten feet of electric wire, 12 feet of hose and a gauge are supplied. The oiling system is designed to prevent oil getting into the tire so that strainers or oil separators are not necessary. The outfit sells for $75.

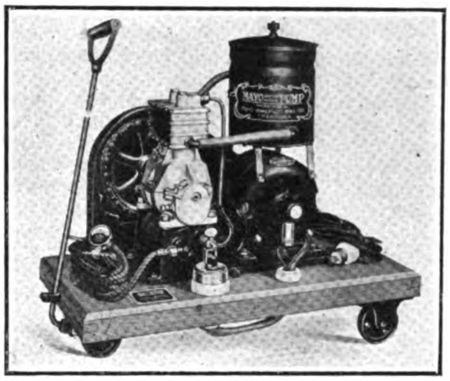

Fig. 1—Mayo electric garage pump

Auto-Comfort Robe.—There is no time that a good robe is more appreciated by the experienced motorist than in the heat of summer, for there is always the possibility of running into rainy weather or experiencing a cold spell, especially in the mountains, that will make a robe almost a necessity.

An interesting all-the-year-round robe is manufactured by L. W. House & Co., Gloversville, N. Y., and illustrated in Fig. 2. As a study of the illustrations will show, this robe can be used in many ways: as a foot warmer, lap robe, or chest protector, and in cold or rainy weather it can be made to completely cover the occupants so that it is not necessary to carry any other wraps.

When the robe is used as a chest protector, the hands, arms and chest as well as the lower part of the body are thoroughly covered and protected from the wind and cold, yet a slight jerk will instantly free each individual.

This robe, which is patented, is manufactured from fur, velour and mackinaw cloth.

In addition spring and summer weight comfort robes for dust protection, as well as warmth on cool evenings, are manufactured by this concern.

St. Louis Battery Charger—To make it possible to charge batteries from an alternating circuit such as is supplied to the ordinary incandescent lamp, the St. Louis Electrical Works, St. Louis, Mo., has announced a mechanical device, Fig. 3, which changes the alternating current into direct at a lower voltage.

Its operation is very simple. The plug provided with the battery charger is screwed into a convenient lamp socket and the current switched on and then the battery is connected.

The advantages claimed for it are that it will charge a dead cell in the proper direction, will not harm the battery by an overcharge, automatically gives the battery a tapered charge, is small and light, will operate on circuits of wide variation of voltage and frequency and does not cost much to run.

It is guaranteed to give satisfactory service and it may be returned if it does not do so.

The price for the 6-volt, 6-ampere size without ammeter to operate from a 100-volt, 60-cycle circuit is $20.

Smooth Cut Grinding Powder—The Smooth Cut Powder Co., Flint, Mich., is manufacturing a grinding and lapping powder for grinding automobile valves, lapping pistons and rings into cylinders and making gas and watertight joints. It contains no emery or metallic substances and does not adhere to the metal so that it can readily be washed off with gasoline or kerosene.

A particular advantage claimed for this compound is that only one grade is required for roughing and finishing. It retails for 40 cents per can.

Automatic Monkey Wrench—The Automatic Wrench Co., Boston, Mass., is manufacturing the Barnsley automatic wrench. This is a quick-acting wrench, which can be quickly adjusted to size and can be used with one hand. It opens automatically, locks automatically and is instantly adjusted. There are no screw adjustments of any kind. There are no teeth and no ratchet. The Barnsley is operated by placing the object to be turned between the jaws and pressing the jaw in until it strikes the object. The patent automatically locking clutch locks it in position. A slight pressure on the clutch and the jaw springs open.

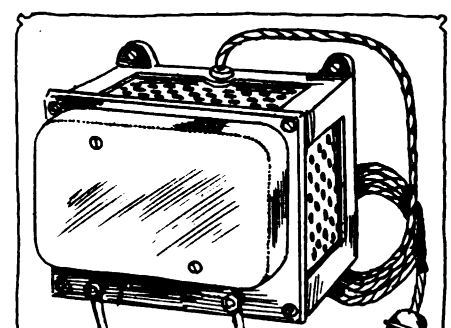

Fig. 3—St. Louis battery charger for charging storage batteries from alternating current lighting circuits

Fig. 2—The Auto-Comfort robe, showing from left to right, the foot pockets, its use as a lap robe, and method of making it into a chest protector

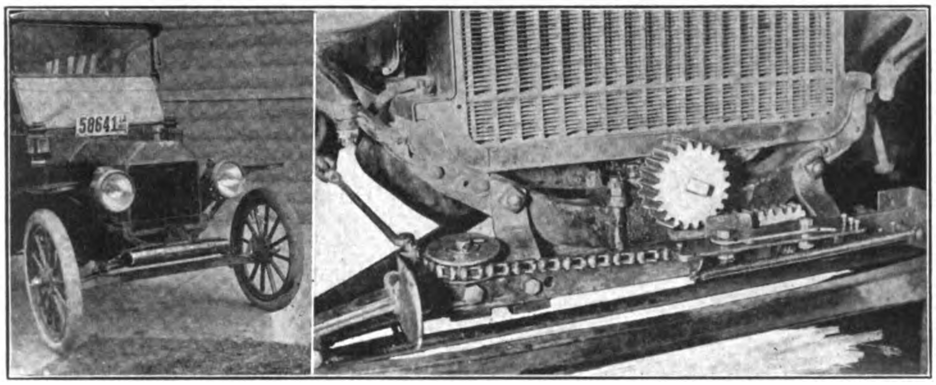

Fig. 4—Two views of Murphy starter, the left one showing its appearance on a Ford, and the right the rack and pinion mechanism which is actuated by a pedal on the foot boards

It is stated that it can be adjusted to one-thousandth of an inch. It is made in four styles, one of which is the S type.

Murphy Starter—For small cars, and especially Fords, a new starter, Fig. 4, is being put upon the market by the Murphy Starter Co., Ida Grove, Ia. It is a mechanical type in which the cranking force is supplied by the foot through a pedal located within easy reach of the driver's feet. Pressure on this lever operates a rack and pinion, the motion being transmitted from one to the other by means of a cable and a chain. The pinion replaces the ordinary starter handle and engages the crankshaft in the same way that the starting handle is engaged. The price of the device for Ford cars is $35 and for larger cars, up to $45.

One-Ton Electric Hoist—The Pawling & Harnischfeger Co., Milwaukee, Wis., is making a 1-ton electric hoist, Fig. 5, that operates on a mono-rail and which is designed to be propelled either by motor or by hand, as desired.

It is stated that it will replace from three to ten men and can be used with great advantage in handling motor and chassis assemblages, etc. It can be quickly installed as it is only necessary to attach the rail to the ceiling.

Another great advantage of the mono-rail system lies in its flexibility. It may be extended indefinitely and it can be made to reach out of the way corners and to cover irregular areas. Different tracks may be connected by means of switches and turntables.

M. P. Motor Tire Pump—The National United Service Co., Detroit, Mich., is marketing a two-cylinder power pump, designed to be connected to the motor car engine. The cylinders are 1⅛ by 1⅝ inches in size. The oil is prevented from getting to the tire by means of a patent air trap. The pump can be mounted by any garageman in any car at small cost, it is stated. Including hose and coupling, the pump costs $25.

Fuller Unit Gearset—Fuller & Sons Mfg. Co., of Kalamazoo, Mich., are now making deliveries of their new Model LV two-speed and reverse, unit power plant, sliding gearset and dry plate multiple disc clutch for cyclecars and similar light vehicles.

The transmission, complete with clutch, weighs only 24½ pounds, and will handle four-cylinder motors 2¾ by 4 and cars weighing up to 1,200 pounds. It has an aluminum case made of the best quality of No. 2 aluminum alloy, hardened 3½ per cent. nickel steel gears, hardened and ground main and countershafts, single row annular ball and Non-Gran phosphor bronze bearings. A drop-forged yoke and hardened and ground yoke bar operate the sliding gear.

The six-facing clutch has the best grade of Raybestos facings which are riveted to saw blade steel discs. The discs are hardened and run with hardened steel pins. A ball thrust bearing with hardened and ground steel plates is used.

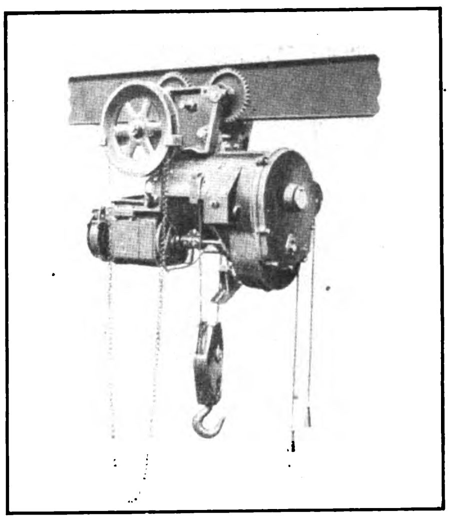

Fig. 5—One-ton electric hoist, which operates on a monorail. The one illustrated is propelled by hand, but the hoist can be motor-driven, if desired

The clutch has large wearing surface, which means long life with no trouble.

The transmission may be taken from the motor by taking out twelve bolts. Clutch and transmission covers may be removed with a screw driver.

With a 2 to 1 gearing on low speed the motor does not have to be raced in order to get into high speed. Also, on average hills this gives a good reduction, which allows a good car speed with a moderate motor speed. This adds much to the comfort of passengers. It also saves wear and tear on the motor and saves gasoline. By having a clutch with large slipping area, a start can be made from either high or low speed under nearly all road conditions. Low speed is used only for starting and in very bad places or on steep hills.

Koklip Mats—F. Cortez Wilson & Co., Chicago, Ill., has recently put on the market a high grade fiber door mat, Fig. 6, that is readily attached to any running board by means of strong tempered steel springs which project underneath and clamp tight. It can be readily removed when desired. Another style with a heavy steel frame all around is also manufactured.

The mats are made in three sizes: 8 by 14, 9 by 16 and 10 by 14 inches, and the price with heavy steel frames is $3.50 each and with clips and spring ends, leaving sides exposed, the price is $2.50.

For preserving the appearance of running boards on demonstrating cars clips and springs for rubber matting are sold for $1.25.

Zone Asbestos Brake Lining—Brake linings by mail is the novel method the Zone Asbestos Brake Lining Co. has adopted for marketing its product. In this way the brake lining goes right from factory to owner and can thus be retailed at a minimum price.

The brake lining is closely woven and is composed of 95 per cent. asbestos. It is stated that it is oil, water, grease and heat proof. Brake linings, complete with rivets, for Ford cars, with postage prepaid, sell for 70 cents, and an idea of the prices of the other linings can be obtained by quoting the 2 by 3/16-in. lining as an example. This sells for 30 cents a foot.

Miller Safety Always Book—A small booklet has recently been issued by the Miller Rubber Co., Akron, O., on the interests of safety, the title of the book being "Safety Always," and the rules to be observed for safety in various cities are given.

Connected with traffic ordinances covering cities in Ohio, New York, Pennsylvania, Indiana, Michigan and Illinois there are special pages devoted to care in driving, rules covering road rights, hints on the prevention of nuisance committed by joy riders and thieves, police traffic signals and the "Twelve Commandments" of driving.

Harwood Cigar Lighter—A combination cigar lighter and cutter for use on motor cars is being marketed by C. F. Harwood, Boston, Mass.; this lighter requiring slight pressure with the thumb for cigar clipping and turning on of the current. The burner then is ready to light the cigar. When the finger is released current is automatically shut off. The lighter, as it is marketed, comes equipped with hook and eye for fastening and 6 feet of cord with plug attachment. It sells for $2.50.

Sturges Shock Absorbers for Fords—The Pacific Leather Works, Oakland, Cal., is marketing a special coil spring type of shock absorber for Ford cars. This consists of a barrel type absorber interposed between the engine spring and the axle. It is constructed with steel drop forgings and the smoothers add 36

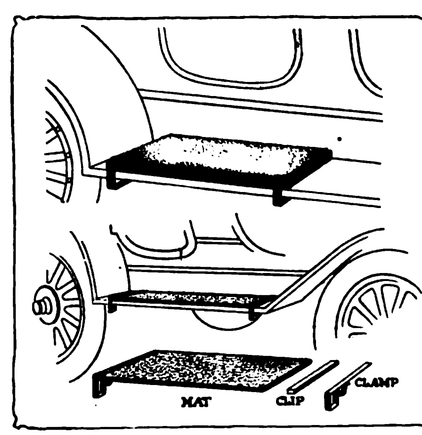

Fig. 6—Koklip mats. The upper view shows a mat with a heavy steel frame running all around it, the middle one shows the mat held by clips, and the lower illustrates the various parts comprising the clips

feet of chrome vanadium ribbon spring to the Ford suspension. It is said to be very easy to apply as no drilling or fitting is necessary. Twenty-five dollars is asked for a set of four.

Abco Lite-Controller—A device, Fig. 7, that serves to prevent an excess of current passing to the lamps whenever the motor is raced on those cars wherein magneto current is used for lighting, has been brought out by the American Battery Co., Chicago, Ill. It is called a Lite-Controller. This device is especially adapted to Ford machines.

In its construction a choke control is employed which generates a back pressure, low in amount at normal speeds but sufficient under high speed to prevent the burning out of the lamps by automatically choking the volume of the current. Under normal operation the device, due to its low electrical resistance absorbs but a nominal amount of current and the brilliancy of the light is not affected.

Means for controlling the current within a considerable range are provided for the reason that some magnetos are stronger than others, and it is not feasible to have the same adjustment for all. When the lever is at the extreme left, or on the first button, the current is entirely off. Normal operation is secured and proper control maintained when the button is at the extreme right. On the second button the maximum checking effect is had and when the magneto current is to be conserved or the headlights dimmed the lever may be put on this button. To meet all magneto conditions three additional steps are provided.

The Abco Lite-Controller is simple in construction, all-metal and is neatly finished. It takes up 3.375 inches on the dash board or cowl and is mounted the same as the ordinary two-point lighting switch which it supplants. The connection posts pass through the dash and to these the connections should be made, one wire running to the magneto and the other to the lights.

J-M Shock Absorber—An inclosed spring type of shock absorber, Fig. 8, that is designed to replace the spring shackles has recently been brought out by the H. W. Johns-Manville Co., New York City. These shock absorbers are to sell at $15 per pair and are made for cars up to 3,500 pounds. For use on Ford cars, the shock absorber will be supplied with a special spring perch to take the place of the Ford spring perch. At a little later date a J-M shock absorber for cars of over 3,500 pounds will be announced.

The construction of this device is extremely simple, employing a unique telescopic, volute compression spring of vanadium steel housed in a cylinder, the upper end of the cylinder being attached to the lower spring eye bolt and the telescopic member of the shock absorber, to which the spring is attached, being fastened to the upper spring eye bolt.

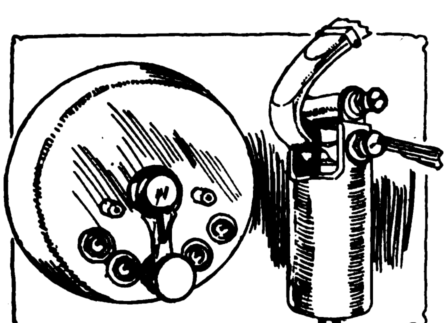

Fig. 7—Left—Abco Lite-controller for regulating the brilliancy of the headlights when the magneto is used as a source of current

Fig. 8—Right—J-M shock absorber for cars up to 3,500 pounds

Gould Storage Battery—Several detail improvements have recently been made in the storage battery manufactured by the Gould Storage Battery Co., 30 East Forty-second street, New York City. The new battery is illustrated in Fig. 9, in two forms.

The plates are of a special type which assures low internal resistance and the active material of the positive plate is said to be harder than that ordinarily used, thus wearing more evenly and making it possible to use a battery with little excess capacity.

A large settling chamber at the bottom of each jar provides for long use without cleaning and thick, rugged separators guard against short circuits. The pillar posts are copper reinforced and the connectors are of copper imbedded in lead so as to reduce the resistance between the cells. The arrangement of the cover is clearly illustrated. Each cell is inclosed by two hard rubber covers and an intermediate layer of sealing compound in adhesive contact with the sides of the jar. Sleeves of corrugated rubber provide some flexibility at the pillar posts, yet make an air-tight joint with the sealing compound.

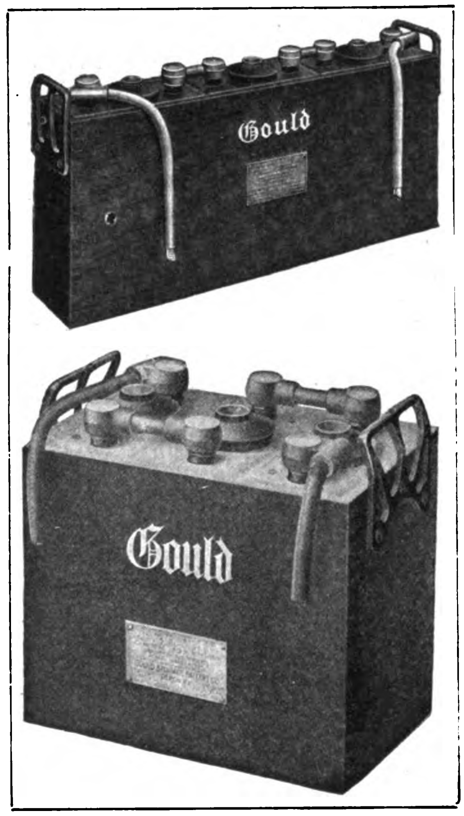

Fig. 9—Two types of storage batteries manufactured by the Gould Storage Battery Co., New York City

Integral with the lower cover is a large expansion chamber communicating with the interior of the cell and provided with a threaded cover. Leakage through the vent is guarded against by the inverted conical shape of the cap, and the removal of the cap provides for inspection and testing of the electrolyte.

The Gould battery boxes are made to the dimensions recently adopted as standard by the S. A. E. and are coated with acid-proof paint. An end-to-end arrangement is available which reduces the thickness to 4.5 inches in the largest size permitting the battery to be suspended between the chassis frame and the running board, concealed by an apron.

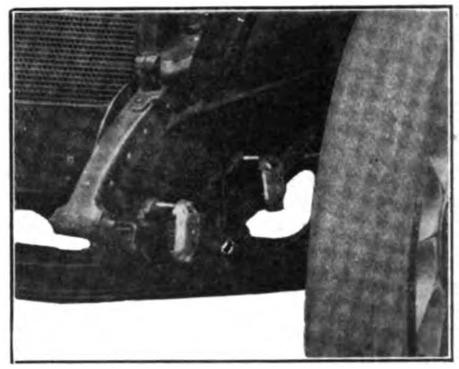

Fig. 10—Brown oil boxes attached to a half-elliptic spring

Brown Oil Boxes—To provide for the proper lubrication of the springs of the car the Brown Trafilog Co., Rose Building, Cleveland, O., has recently brought out a device called an oil box, which is designed to be attached to the springs, as shown in Fig. 10. One box is bolted on each side of each clip, and therefore on a three-quarter elliptic there would be three boxes.

The boxes contain pads which are saturated with oil and this works into the spaces between the leaves of the springs, loosens the rust and stops the squeaks, and also makes the car easier riding, it is stated. If the springs are very rusty the pads should be saturated with one-fourth kerosene, otherwise any ordinary light-weight oil should be used undiluted.

The clamps are attached to the sides of the leaves with the oil holes up and from 6 to 9 inches from the clip. Various sizes are made to correspond with the different sizes of springs.

Icy-Hot Bottles—Increased strength is the feature of the latest bottles manufactured by the Icy-Hot Bottle Co., Cincinnati, O. These bottles are insulated by a vacuum between the outer casing, which is made of metal, and the inner part, which holds the liquid, and is made of glass. The neck of the bottle is held in the metal casing by a rubber ring and at the base of the glass bottle there is a padded spring which absorbs the jars and jolts due to falling over and dropping.

Every Icy-Hot is guaranteed to keep hot liquids hot for 24 hours or cold liquids cold for 3 days, regardless of outside temperatures. Several convenient styles are made for the automobilist. A tourist style sells for $2.50 and $3.50 in pint and quart sizes when finished in nickel plate, and when leather trimmed they cost $1.25 and $2.25 extra. There are many other types, and in addition convenient cases for carrying two or more bottles are made.

Hinson Endless Fan Belt—At the low price of 25 cents the C. & B. Hinson Co., Cincinnati, O., is marketing an endless fabric belt for Ford cars. This belt is made of linen and cotton fabric tape, put together by special machinery. It is wound into a four-ply endless belt, then stitched with six rows of linen thread. It is said to be proof against oil, heat and water and will not stretch, and, furthermore, that it is three times as strong as a leather belt of the same thickness.

Search Sign Lamp—Every motorist knows how hard it is to read signs along the road at night, it generally being necessary to dismount from the car and grope one's way to the sign post and then read the directions by the uncertain light of a match.

To overcome this difficulty a lamp, Fig. 11, that can be clamped to the windshield or any other convenient place has been brought out. It has an adjustable swivel action and thus can be moved in any position and clamped there. A handle on the back facilitates its movement. It is lighted by electricity. The price is $10.

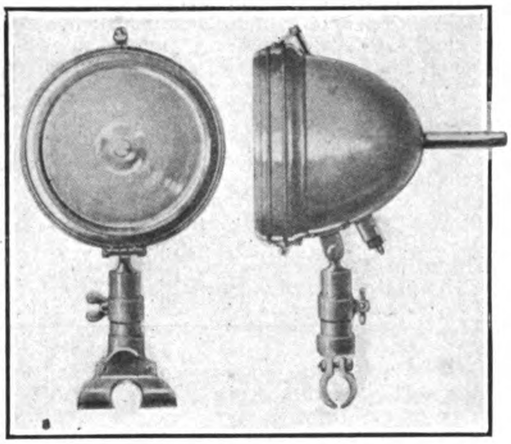

Fig. 11—Search sign lamp, which is for reading signs along the road

Isometric Sketching Paper—A specially ruled paper, Fig. 12, to enable the designer or draftsman to make sketches or drawings in isometric perspective without difficulty and without the necessity of understanding the principles of free hand drawing has been brought out by the N. W. Henley Co., New York City.

Shop details and assembly drawings can be quickly drawn on it and thus a great deal of time can often be saved because one drawing can be made to take the place of three. It also has the advantage that it is easier to understand a drawing in perspective.

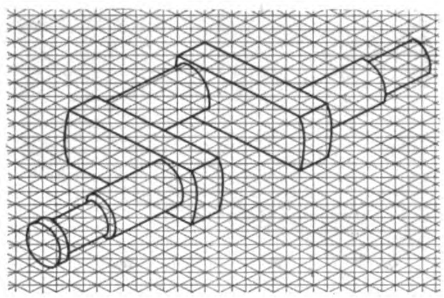

Fig. 12—Isometric sketching paper to enable a draftsman to make drawings in isometric perspective

Houdaille Shock Absorbers—Houdaille shock absorbers, made by Leuaous, Paris, France, and distributed in America by the Benz Automobile Sales Corp., New York, N. Y., operates on a principle identical with that of the recoil absorbing device used on cannons. The compensating suspension is made positive by a rotary paddle piston compressing castor oil and forcing it through by-passes provided for the purpose, the oil thus forced by abnormal pressure through the by-pass automatically deadens the jar. The recoil is eliminated by action of the oil being returned from the compensating reservoir by means of such. These list at $90 per set of four.

Spare Tire Holder—Patent papers have just been issued to Wilbur N. Urskine, Evansville, Ind., on a locking spare tire holder, Fig. 13, and is to be put on the market by him, manufacturing arrangements having been practically completed. The tire holder consists of a Y-shaped standard, which is bolted in an upright position to the running board or to the rear of the car, the ends of the wire taking the tire or demountable rim. A feature of the device is the locking arrangement by which a clamp is placed over the lower portion of the rim and held by a pin to the standard, which in turn carries the padlock, thus preventing theft of the tire.

F. & H. Drip Pan—A drip pan that need never be cleaned and therefore is especially adapted to garages and showrooms is announced by the Foss-Hughes Co., Philadelphia, Pa. This pan is in the form of a wooden retainer which holds a number of sheets of detachable oil-proof paper, as shown in Fig. 14. As each sheet becomes soiled it is removed the same as a sheet is torn off of a pad of paper, and in this way a clean surface is obtained without the necessity of cleaning the pan. The pan sells for $5.

Chicago Dimmer—To eliminate the glare of the headlights, and thus allow the motorist to use his headlights in the city without breaking the law and also to make driving in the country more safe for approaching cars and other vehicles and pedestrians, the Chicago Dimmer Co. has brought out a simple shutter device made of translucent material which can be easily attached to any lamp in 15 minutes by simply unfastening the reflector from the lamp door, inserting the Dimmer back of the glass and fastening the reflector in place again.

The Dimmer is opened and closed by a slight movement of a handle placed within easy reach of the driver and when closed gives a perfectly diffused light. The device has been approved by the Board of Motor Headlight Inspection, Chicago, Ill., and is sold for $7.50, f.o.b. Chicago.

El Arco Radiators—A pointed, V-type radiator for the Ford car is one of the specialties of the El Arco Radiator Co., New York.

Stickalite—Repairs or adjustments at night by the roadside are greatly facilitated when there is a good light to work by and acting on this idea the Premier Electric Co., 4048 Ravenswood avenue, Chicago, Ill., has put on the market an electric lamp with a magnetic base. The lamp is designed to be operated from the ordinary 6-volt circuit and will stick to any iron or steel surface. It weighs 3 ounces and the magnet has a pull of 50 times this amount so there is no possibility of the lamp not staying where it is placed. A sufficient amount of cord is furnished with the lamp and a standard Ediswan socket is provided. The price is $1.

Gray & Davis Book—A Little Journey Through a Great Factory, is the title of an interesting and instructive book that is published, for private distribution by Gray & Davis, Inc., Boston, Mass., manufacturer of starting and lighting systems, and electric lamps for automobiles. The book consists of 40 pages of half-tone pictures of the company's factory and presents in an interesting way the details of electrical instrument manufacture and in addition it shows the care that has been taken in providing a pleasant and healthful place for its employees.

Quick-Tite Patch—A patch, in the form of a roll 15 inches by 3 inches, placed in an air-tight, oil-proof, fibre case with a pair of shears, making a complete repair kit for inner tubes, is made by the Quick-Tite Patch Co., Amsterdam, N. Y.

To use the patch, clean the tube with gasoline in the same manner as when any patch is applied. Then cut off the proper sized patch and clean the prepared side thoroughly and press it into place with the fingers. Place the tube in the shoe and inflate to the required pressure. A permanent repair is the result and the hotter the tire becomes the tighter the patch sticks, it is stated.

The patch and the outfit that goes with it retails for $1.

M & M Bodies—The M & M Co., Cleveland, O., has for sale a limited number of new four-door, streamline bodies, already painted and upholstered. It is stated that it cost $350 to make these bodies and they are offered at $85.

The bodies are painted maroon, dark brown and dark green and are upholstered with genuine first quality leather, it is said. There is room under the front seat to accommodate a large tank and the cowl is arranged for the insertion of electric lights, speedometer, etc.

The AUTOMOBILE

Germany 1, 2 and 3

Mercedes Wins Grand Prix—Takes First Three Places—France Gets Fourth with England Fifth —Boillot Leads but Goes Out in Last Lap

By W. F. Bradley

LYONS, FRANCE, GRAND PRIX RACE COURSE, July 4—*Special Cable*—Germany today won positions one, two and three in the Grand Prix race, the road classic of Europe, defeating a dozen others of the greatest builders of racing machines in Europe and lowering the colors of France, which have floated victorious in French road racing for so many years.

Rarely before, in spite of its historic significance, has the name of Mercedes been higher in the motoring heavens than tonight, for three Mercedes cars flashed winners across the finishing line at the end of the 467.5-mile race over the tortuous 23.3-mile circuit located a few miles out of the city of Lyons.

Lautenschlager, who 8 years ago wrested the Grand Prix race from France in a Mercedes, today was winner, covering the distance in 7 hours, 8 minutes and 18 seconds, a speed of 65.55 miles per hour. His teammates, Wagner, one-time winner of the American Grand Prix race on the Savannah course, and Salzer were second and third. Peugeot was fourth, and the English sunbeam fifth.

The Race

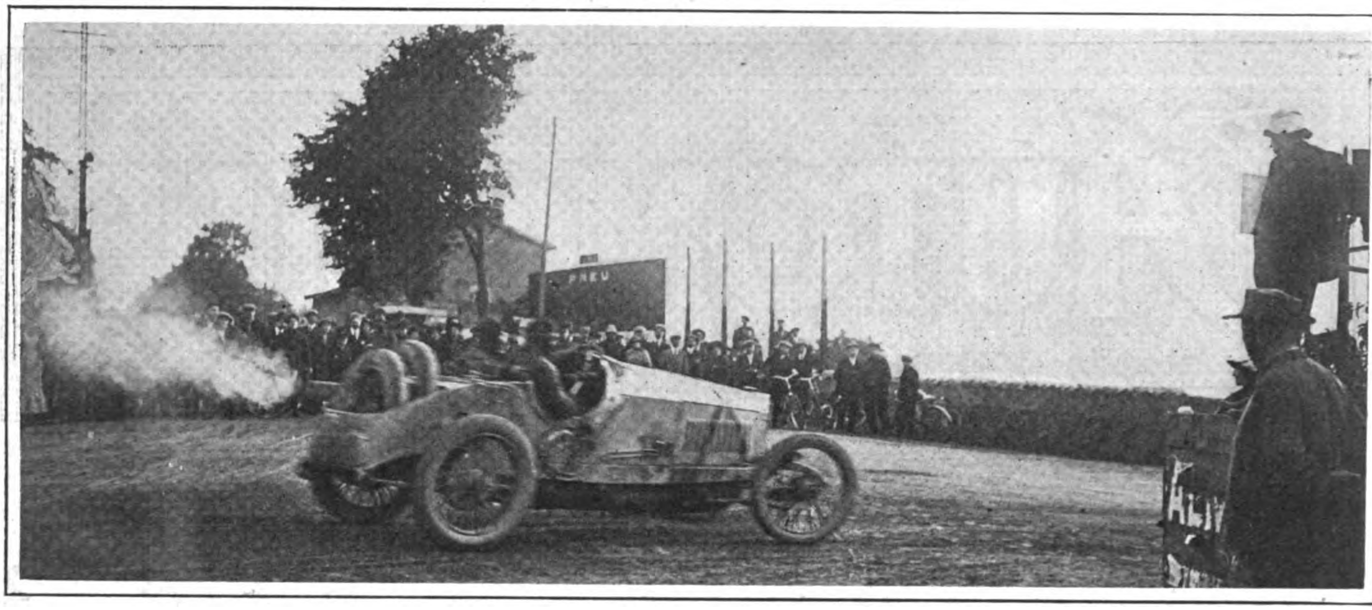
CAR	DRIVER	SPEED
Mercedes	Lautenschlager	65.55
Mercedes	Wagner	65.40
Mercedes	Salzer	64.8
Peugeot	Goux	64.4
Sunbeam	Resta	62.6
Nagant	Esser	61.0
Peugeot	Rigal	60.6
Delage	Duray	59.7
Schneider	Champoiseau	57.7
Opel	Joerns	56.5
Fiat	Fagnano	55.5

LAUTENSCHLAGER and Mechanician in Winning Mercedes

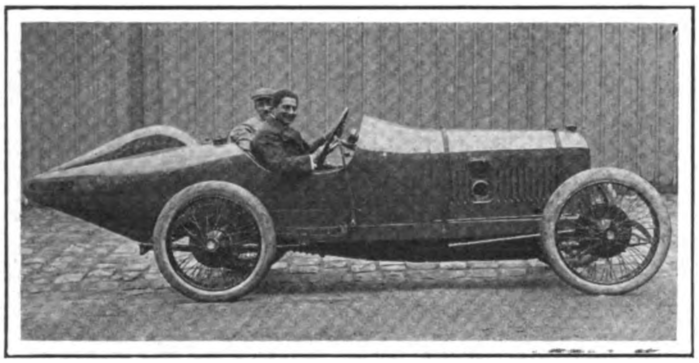
Today has been a clean sweep for the German eagle; in fact, never before has any one maker captured the first three places in so important a racing event.

The best France could do was to have Jules Goux land his Peugeot in fourth place 9.5 minutes back of Lautenschlager and a good 4.5 minutes back of the third Mercedes. It was no case of victory by a few seconds but by a clear margin of several minutes.

But if Mercedes cleared the slate, winning first three places it was not until after the eleventh hour that victory was hers and it was not until a few minutes before the finish that the 300,000 spectators around the course realized that the



Lautenschlager, the winner, sending his Mercedes around the Grand Prix course at top speed



Boillot on 1914 Grand Prix Peugeot

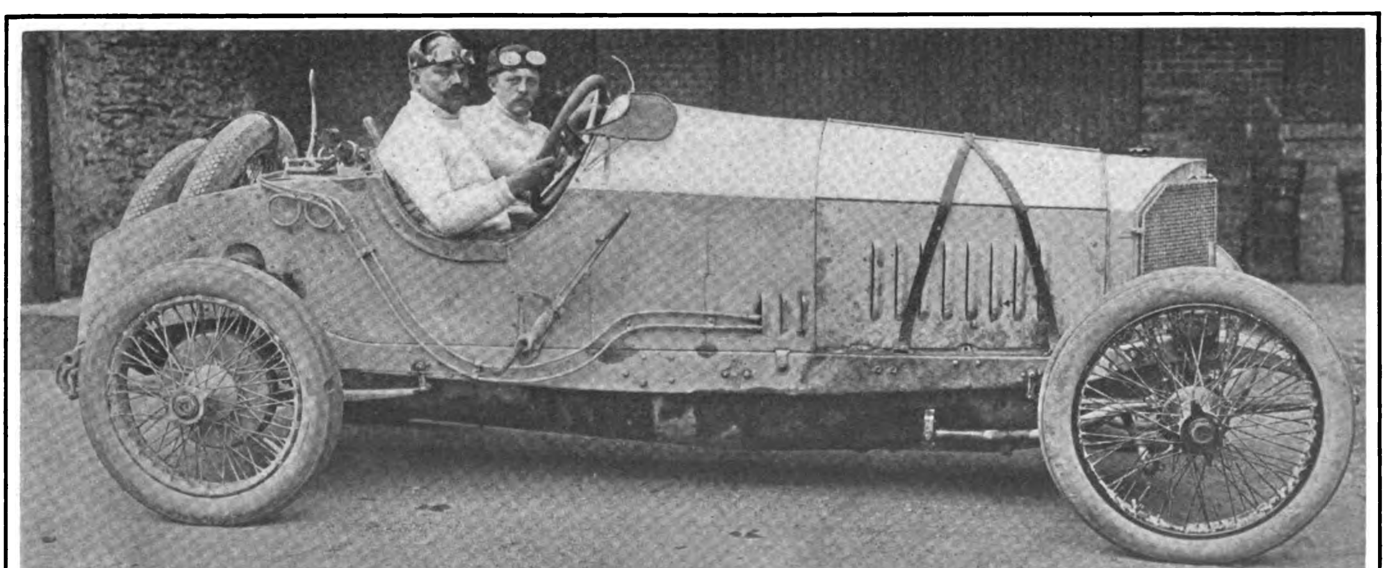
Tricolor of France was lowered and the banner of Germany floating in the zephyrs of victory.

Boillot, winner of the French Grand Prix last year and the year before, was looked upon as the hero today to again carry France to the fore, and his performance justified such expectation, but when half a lap, a short 10 miles from the finish, his Peugeot failed him, the motor broke down, and, heart-broken, he threw up both hands and withdrew.

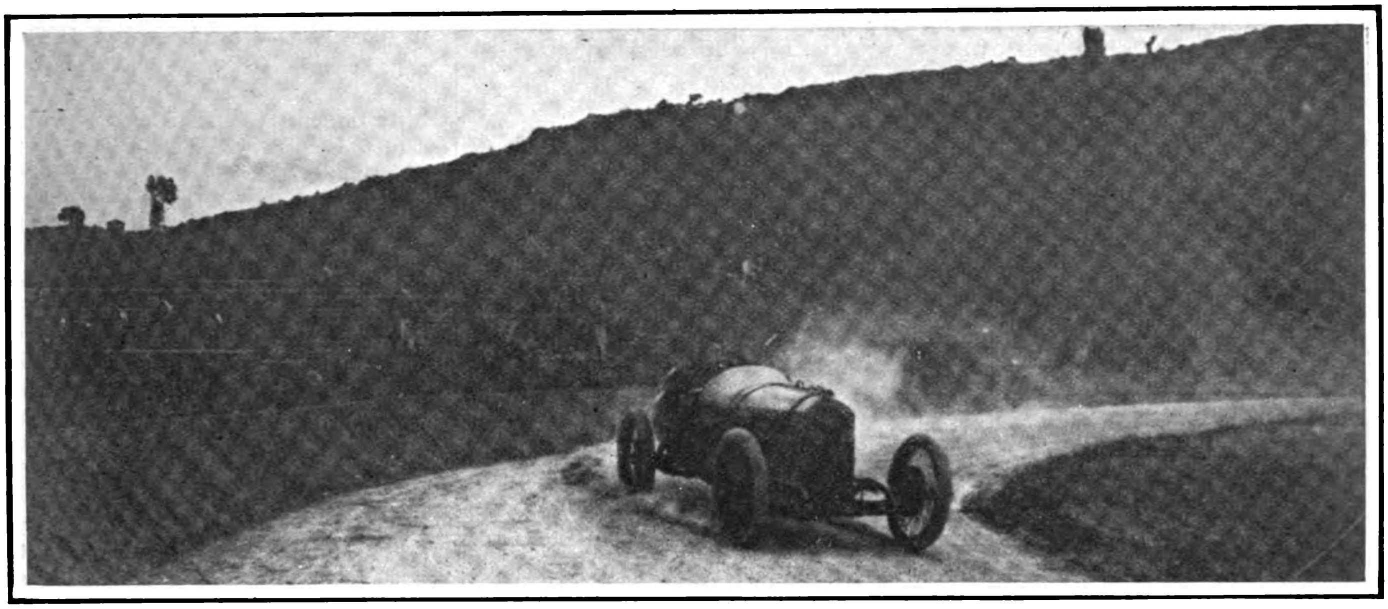
Boillot had fought with the desperation of a demon from start to finish, for not during a single moment was he free from the terrific onslaught of the five Mercedes cars. Every moment they used German wiles and German force to wear out the greatest road driver that France has produced since the days of Thery, who won three Gordon Bennett races in successive years. Boillot, a man of magnificent stature, and incomparable driving ability, fought the Germans off one by one only to fail when nearly through.

From the start Sailer, driving a Mercedes, set out to maintain a gruelling pace that would wear out any ordinary driver. For five laps, or over 110 miles he kept up the pace and led the field with less than 2 minutes lead on Boillot, who was third, and Duray in a Delage, second. Then Sailer dropped out and Boillot leaped into the lead, having passed the Delage in a few minutes.

When the race was half over, at 230 miles, Boillot was 1 minute and 14 seconds ahead of Lautenschlager, and his team-mate Goux had his Peugeot in third place a good minute ahead of Wagner in another Mercedes and Salzer in the third. At this time Pilette, driving the fifth Mercedes, was out, leaving the trio of Lautenschlager, Wagner and Salzer to worry Boillot and Goux.



Lautenschlager, the winner, in a winning Mercedes, photographed just before the beginning of the French Grand Prix on July 4



Boillot taking one of the sharp turns on the winding descent to the grandstands on the French Grand Prix course

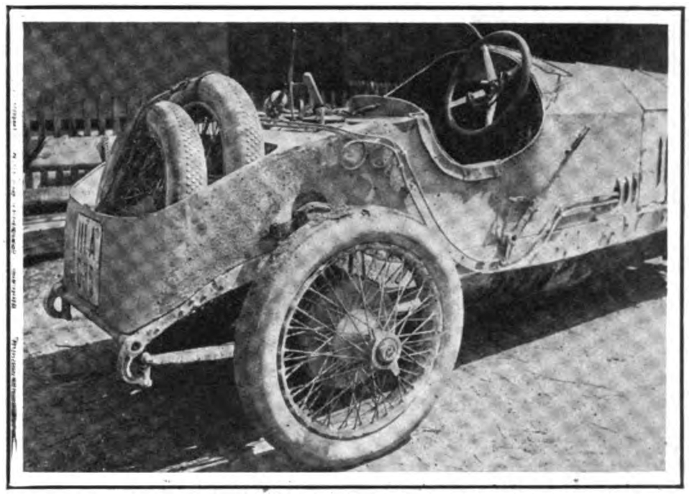
Still Boillot held the lead. Soon after the halfway point, Lautenschlager stopped for gasoline and oil, but instead of Goux stepping into second place as Boillot had hoped his teammate would do, it was the wily Wagner who had passed Goux and was second. A lap later when Wagner had to stop for gasoline and oil, as arranged, it was Lautenschlager who jumped into second position instead of Goux.

There was not a second of letup to the pressure of the German combination. The Mercedes trio fought along lines of a well-laid out plan.

Still Boillot hurled his Peugeot along, maintaining the lead lap after lap until the seventeenth arrived, and but three more had to be covered. For the first time in the race the situation of France became alarmingly critical. Boillot had but 14 seconds' lead on Lautenschlager, Wagner and Salzer were leading Goux, the other hope of France, and Delage, Schneider and other French cars were further to the rear. Peugeot must save the day or France be crestfallen.

From the Peugeot pits was sent out the signal to Boillot to drive still harder: "Drive like hell" was the order. Boillot and Goux responded, but their herculean efforts failed.

When the eighteenth lap was over Lautenschlager had pushed his Mercedes to the fore and had a clear lead of 33 seconds on Boillot.



Location of fuel tank and cradle for tires on Mercedes

Once again the signals flashed from the Peugeot pit to Boillot to drive still harder. Boillot started into the nineteenth in good shape, but soon signals of distress came. His speed was failing, the motor was not up to par.

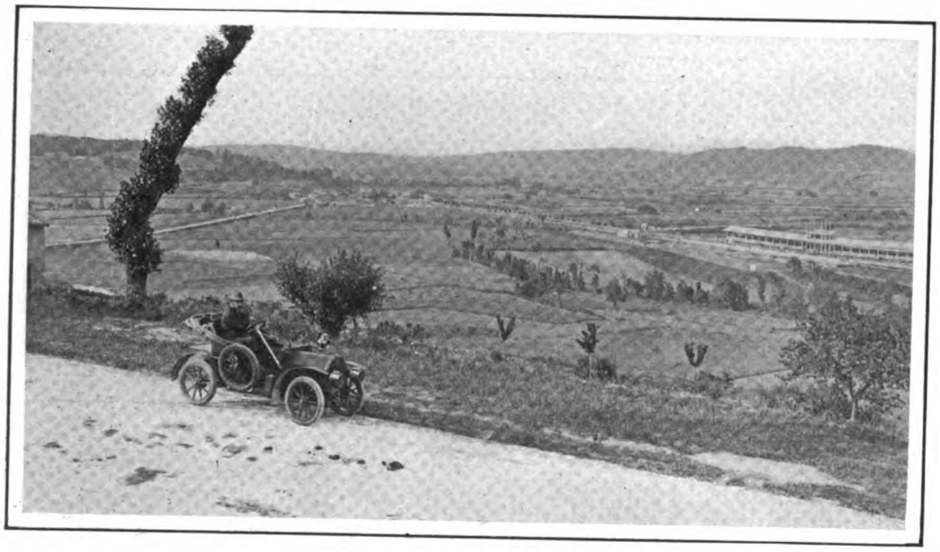
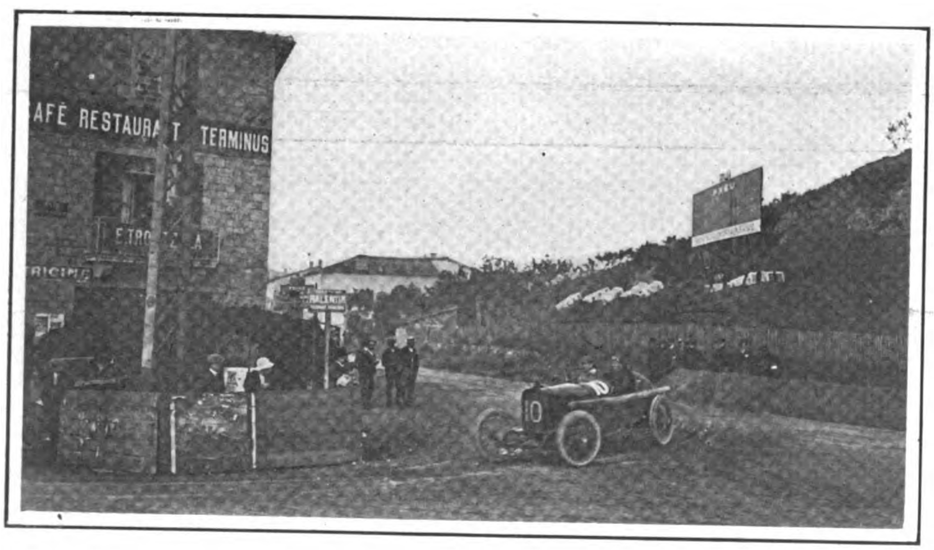
Fagnano in the Flat swinging around Death Corner on the Grand Prix course



View of Grand Prix course near end of third leg, and grandstand stretch



Jean Chassagne on the hairpin turn on the grandstand stretch

Lautenschlager was gaining. He jumped his lead to 77 seconds at the end of the nineteenth lap.

But one hope remained for France: "Would the Germans have tire trouble?" But the tire troubles did not come. Boillot, when half through his twentieth lap, was out. His motor broke down, nobody at this writing knows exactly why. Boillot withdrew to the side of the road and France's last hope was dashed to earth.

At the outset of the race it was evident that there would be a keen struggle between the Mercedes and Peugeot cars, and that the Delages would not be factors, although Duray was piloting one of the fastest of them.

Although victors tonight, the Mercedes team of five met two foemen in Boillot and Goux well worthy of their steel, and had the two Peugeot pilots been backed by three such other teammates as comprised the German team, it is questionable if the world would ever have seen a greater struggle. The Mercedes and Peugeot cars behaved admirably and their relative abilities on the road are well illustrated by the struggle which the grandstand witnessed between Lautenschlager and Goux in the fifteenth lap.

A Neck-and-Neck Race

Lautenschlager and Goux were almost neck and neck on the winding descent opposite the grandstand. Goux was slightly behind, but with his front wheel brakes he could approach the curves at a higher speed than the Mercedes. At Death Corner he was afraid to take the risk. At 150 yards farther on at the second bend he was within arm's length of Lautenschlager, but again he dared not pass him. The same thing happened on the third bend of the course. Finally the two racers reached the straightaway down stretch approaching Sept Chemins hairpin turn. Here Goux opened up the Peugeot to the full, and after running wheel to wheel for a few yards got ahead of Lautenschlager 20 yards before the turn was reached. Goux thus passed in front of the grandstand a couple of seconds ahead of Lautenschlager, but although he was leading in road position, he was still behind the German on elapsed time. It was not long before Lautenschlager again passed the Peugeot.

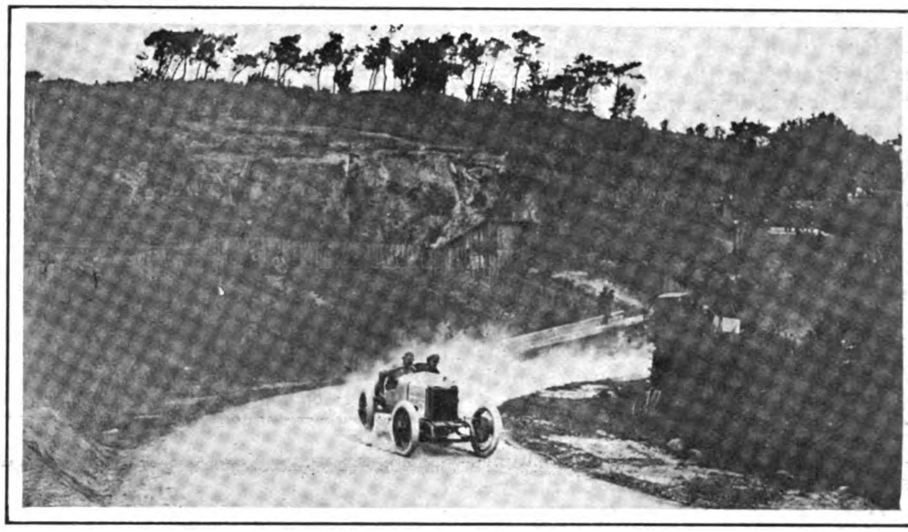
Germany Prevails

The three Germans drove a hounding race like this from start to finish, and by sheer might wore down Boillot and Goux, who were pushed as never before in a road race. The Mercedes drivers with three of them running so strongly could afford to take chances of which Boillot was afraid.

But little better fortune awaited Goux in the other Peugeot. On the last lap but one he lost third position to Salzer, driving the Mercedes, and finally came in fourth, exactly 9.5 minutes back of the winning Lautenschlager.

That but eleven of the thirty-eight cars to start were able to finish proved the gruelling nature of the struggle. Over 300,000 spectators watched the contest which was remarkably free from accidents from start to finish, only two drivers suffering slight injuries. One of these was Sisz, familiar to American readers as having won the first French Grand Prix in a Renault and having competed in American Grand Prize races on the Savannah course in a similar make of car. Today he drove an Alda and raced in hard luck throughout. He changed a radiator early in the race and later was working on a tire by the roadside when he was struck by one of the Opels. His shoulder was dislocated and he was severely bruised. The mechanician brought the car to the pits where it remained.

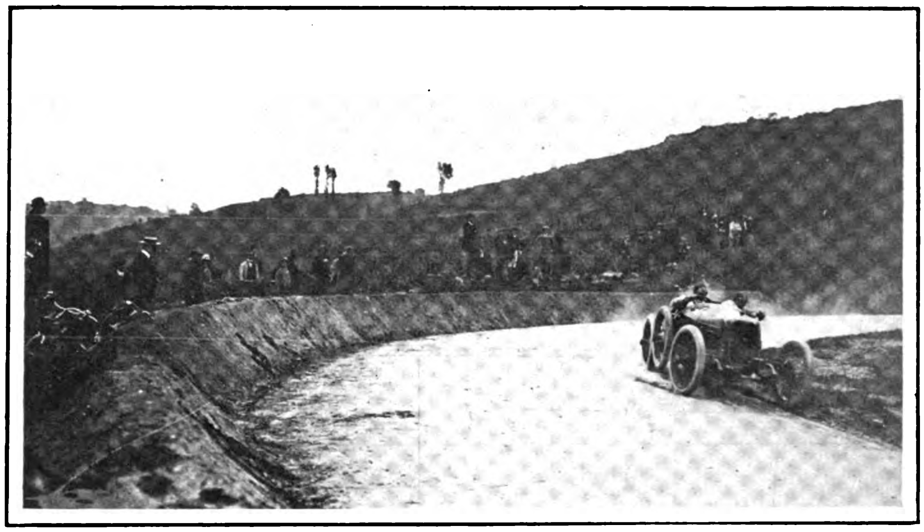
Tabuteau, in another Alda, overturned on a difficult winding stretch of the road, but was not severely injured.



Opel on hairpin turn near the grandstands on French Grand Prix course

Delage Fast in Trials

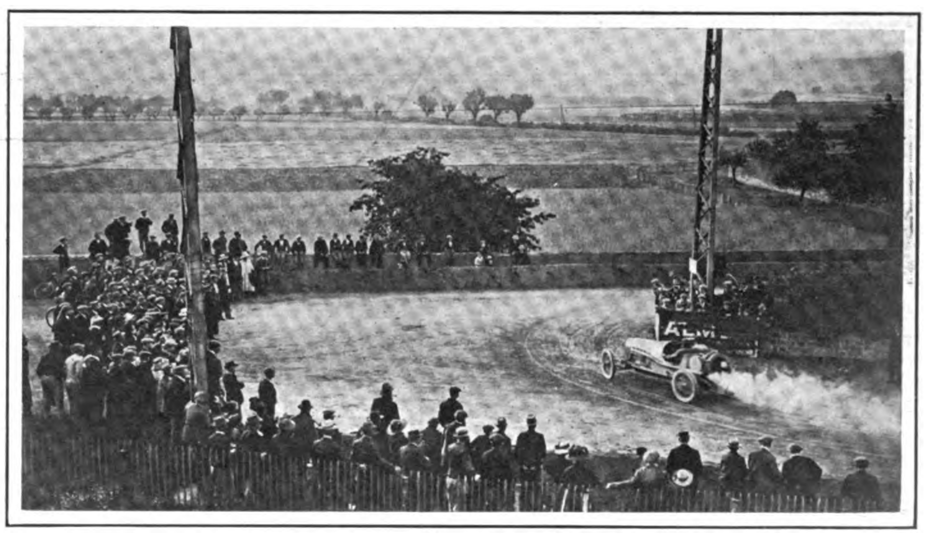
In the trials the Delage cars had shown themselves faster than the Peugeots and quite the equal of the Mercedes. They had been prepared with minute care. The race was scarcely started when it was seen that Bablot, one of the drivers, and the most reckless of the trio, had comparatively little speed. Guyot, one of the other Delage pilots, who recently won fourth place at Indianapolis, could not make more than a commonplace showing.



Bablot on the Delage swinging around the turn near the grandstands

Before the race all three of the Delages had experienced trouble with backfiring into the carbureters, and thinking to obviate this defect, which was supposed to arise from a slightly imperfect seating of the positively operated valves, which are opened and closed by cams, rather than the closing being effected by a spring, a new adjustment was made a few hours before the start of the race. This proved a costly error, for immediately the speed of the engine dropped and the engine power was cut down considerably. Bablot never got better than twelfth place, and Guyot once reached eighth position. Finally both Bablot and Guyot withdrew disheartened, two laps before the finish of the race rather than come in tail-enders.

This was the first occasion in which the Delage in a French race has failed to finish a complete team of three cars.



Scales on the Flat hugging the pole on Death Turn

One English Finisher

England, represented by six cars, three Sunbeams and three Vauxhalls, had but one finisher of the eleven starters, Resta finishing in a Sunbeam in fifth place. The Vauxhall cars are considered the finest racing productions and represent the most up-to-date design, but they were too green for a contest of this nature. The cars and drivers were altogether unprepared for the race, and it was with difficulty that the cars were ready in time to be weighed in, and only 24 hours before the start of the race all three were completely dismounted. Ralph DePalma, the American driver, pilot of one machine, realized before starting that he had little chance of finishing. Hancock, driving one of the Vauxhalls, was more than 2 hours making the first lap, at the end of which he abandoned the race. Watson, one of the other drivers, required about the same time to complete the circuit and withdrew, leaving only DePalma, who struggled hard against fate, covering the first lap in 26:29, as compared with 21:11, the best time for the initial circuit, made by Sailer in the Mercedes. DePalma completed the second circuit in about the same time, was a little faster in the third and fourth, and after he had completed the fifth he pushed his car off to the side of the road.

The three Sunbeam cars made a better showing, and although Resta was but able to get fifth place, the Sunbeam was the third make of car to finish. When five laps, or the first quarter of the race was over, Guinness, driving a Sunbeam, and the winner of the recent Isle of Man road race, was in fourth position, scarcely 2 minutes behind Sailer, the Mercedes that was leading at that point, and ahead of Lautenschlager, Goux and Wagner. Chassagne, driving another Sunbeam, was in twelfth place, and Resta was further back. With the race half over, Guinness withdrew with a broken piston head, having held fourth position from the fifth lap until that time. Chassagne was forced out on the thirteenth lap when running in seventh place, due to a broken bolt on the end of a connecting-rod. The performance of Resta was a consistent one from start to finish. At the end of the first quarter he was below fifteenth place; when the

Champoiseau on Schneider. Note form of bonnet with radiator in front under hood

race was half over he was in eighth place, and at the finish he was fifth with his car working perfectly.

The three new Fiat cars made a favorable impression, and one of them, driven by Fagnano, finished eleventh, 34 minutes back of the leader. Cagno, one of the Fiat drivers, had trouble with pre-ignition from the start of the race, and this trouble also delayed Scales, driving the third Fiat. Fagnano drove a consistent race and was in ninth position at the end of five laps with his teammate, Scales, in eleventh place. At the halfway point Fagnano was seventh.

Felice Nazzaro, an Italian race driver, well known in America, from the days when he piloted Fiat cars, had three of his new Nazzaro machines entered, none of which was ever important factors in the race. Nazzaro, himself piloting one, was forced to abandon the contest early.

Switzerland was represented by two Piccard-Pictets, which are single sleeve motors, built under the Argyll license. Each sleeve has a double movement, a reciprocating one and a part rotating one. The sleeves gave no trouble, but both cars were withdrawn, due to chassis defects.

All Cars Are of Special Design

Participants in Grand Prix Embody Latest European Engineering Developments

LYONS, FRANCE, June 24—Of the thirty-eight cars to start in the Grand Prix race here on July 4, which represent thirteen different European makers, two restrictions have been kept in mind:

First: The piston displacement is 4 1-2 liters, in other words 274.6 cubic inches. This means a four-cylinder motor of approximately 3 13-16 x 6-inch bore and stroke. In reality the majority of the cars entered are 3.7 x 6.3 inches, which in millimeters is 94 x 160. Some of them are 93 x 165. In not a single case is the stroke-bore ratio 2 to 1. It is 1.4 to 1 in Fiat and Vauxhall, 1.83 to 1 in Peugeot and 1.7 to 1 in practically all of the others.

Second: These thirteen manufacturers have had to build to a weight not exceeding 2,425 pounds total. This has meant a careful selection of material, using the best steels and proportioning weight to strength.

Six Nations Represented

For the first time since France has held a Grand Prix, this race is really international, in that France has twelve cars, representing four companies; Germany has eight, representing three companies; England has six, representing two companies; Italy has nine, representing three companies; and Switzerland and Belgium two each representing one firm. Mercedes has five cars entered, and the majority of the other makers three each.

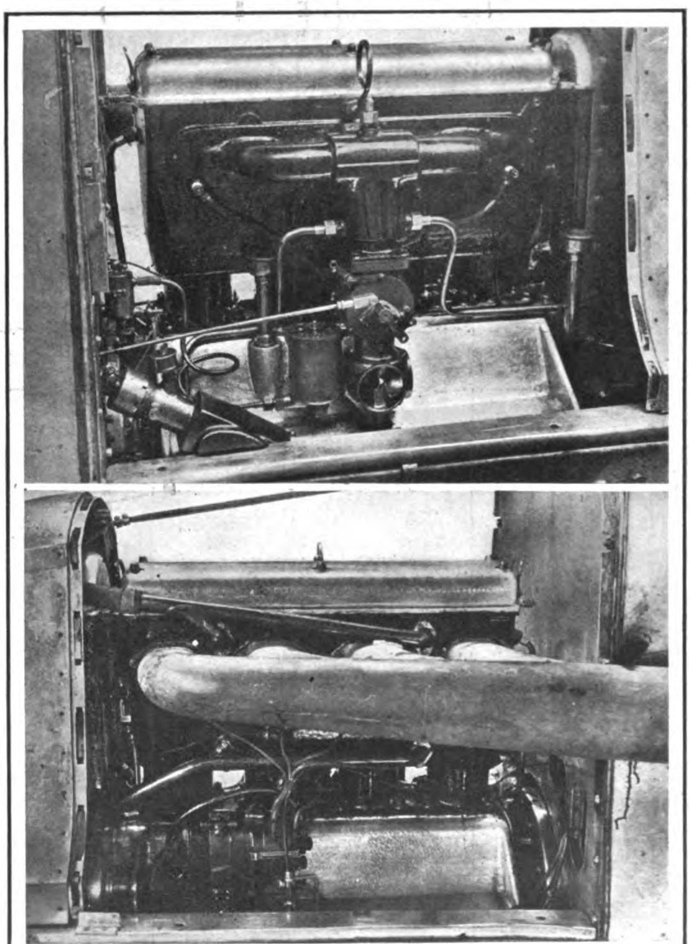
All of the cars without a single exception have been built to meet the requirements of the rules, and it is impossible to find a single car that has been assembled from stock parts and has been entered with the view of cheap publicity. All are the epitome of the best that Europe can provide in design and construction. Their secrets are vigilantly guarded and Mercedes has refused to give any information on its motors.

Four-Cylinder Motors Supreme

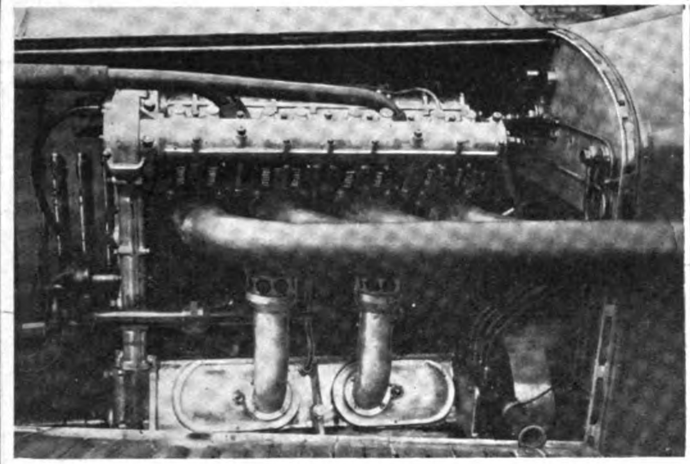
All of the motors are four-cylinder types with the single exception of the Aquila-Italiana, which uses a six, and which may not start in the race.

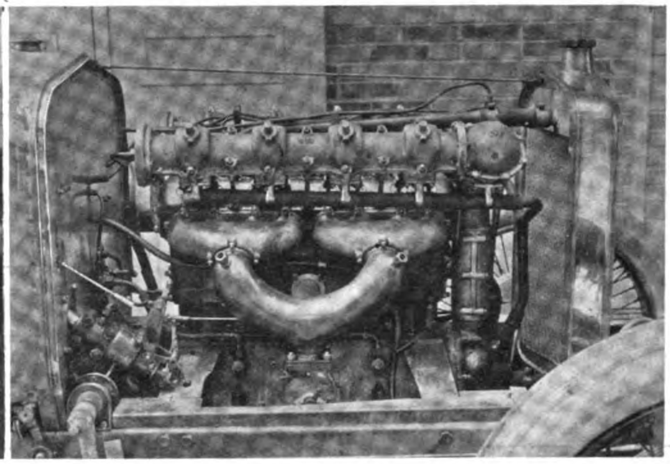
With but the single exception of the Mercedes, block castings are used on all the motors, the Mercedes company using separate forged-steel cylinders to which the water-jacket is welded. Mercedes built two sets of cars for this race, one with six-cylinder motors, the other with four cylinder ones, and after long road tests decided in favor of the fours.

All cars show a decided trend towards the use of ball bearings for the crankshaft, 6 of the 13 makes using them. Six others employ plain bearings and one uses roller. Built-up crankshafts made from two or more pieces are frequently necessary in order to properly fit the ball bearings.



Upper—Intake side of Alda motor. Lower—Exhaust side of Alda motor with sixteen overhead valves





Left—Exhaust side of Peugeot motor. Right—Intake side Delage sixteen-valve motor without valve springs

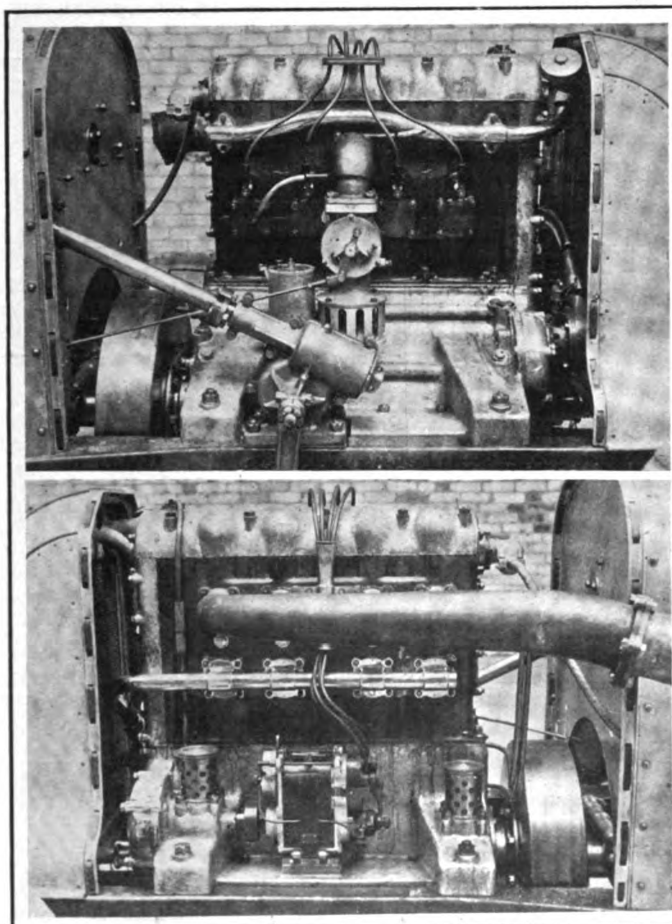
At this date it is impossible to get the exact valve sizes, but in several of the best cars where there are four valves per cylinder the diameters range between 1.7 and 1.8 inches.

Valve Timing Figures

Valve timing is also difficult to obtain and the following may be taken as approximately that of three of the leading makes:

Intake opens 12 degrees after center; intake closes 45 degrees after center; exhaust opens 45 degrees before center; and exhaust closes 18 degrees after center.

Great attention has been given to details of lubrication, and there is a tendency towards the use of a system in which all oil is pumped out of the base chamber, being delivered to the bearings from a tank set elsewhere in the frame. Thus isolated from the heat of the motor the oil cools before being circulated through the bearings.



Upper—Intake side of Schneider motor. Note radiator filler cap under hood Lower—Exhaust side of Schneider motor

Double Magnetos in Vogue

Single and double high-tension magnetos are equally employed. By double ignition is meant one magneto with two distributors, firing two plugs in synchronism in each cylinder. Mercedes has gone further, firing four plugs in synchronism in each cylinder, by means of fitting two double magnetos.

Pump circulation of the water is used in every case, even where stock models use thermo-syphon. Two firms that have carried the radiator on the dash in stock productions have fitted it in front in their racers.

Four-Speed Gearbox Essential

The nature of the 23-mile course has made a four-speed gearbox essential. There are some straightaway stretches of a switchback nature where the limit of speed is the ability of the car to hold the road. Because of this several makers are using a geared up fourth with direct on third. Delage uses 5 forward speeds with fourth and fifth geared up. Nagant uses 5 speeds with fourth direct and fifth geared up.

Every car is shaft driven with a bevel rear axle. In general springs are relied upon to take the drive and the torque.

Brakes have received much attention because of the many curves on the course, Delage, Peugeot, Fiat, and Piccard-Pictet fitting front wheel brakes. Every car in the race has wire wheels, which is ample proof of the merit of these wheels when the tortuous nature of the course is considered.

The keynote of all the motors is the hemispherical type of combustion chamber together with overhead valves and some form of overhead valve mechanism. This design is found on every car in the race, excepting the Piccard-Pictet, which is a single-sleeve type built on the Argyll patents with the sleeve reciprocating and also giving to and fro rotary motion.

Sixteen Valves the Rage

Some of the leading valve arrangements are illustrated on these pages. Of the thirteen different makes of cars, nine are designed with four valves in the head of each cylinder, two intakes and two exhausts, the only two companies of note using but two valves per cylinder being Fiat and Schneider. Where the valves are inclined at 45 degrees or thereabouts, two camshafts are generally used, but where the valves are mounted vertically in the cylinder head, one overhead camshaft suffices.

All entrants have recognized the superiority of the overhead valves and firms which a year ago raced with L or T-head motors have been obliged to come out boldly for the

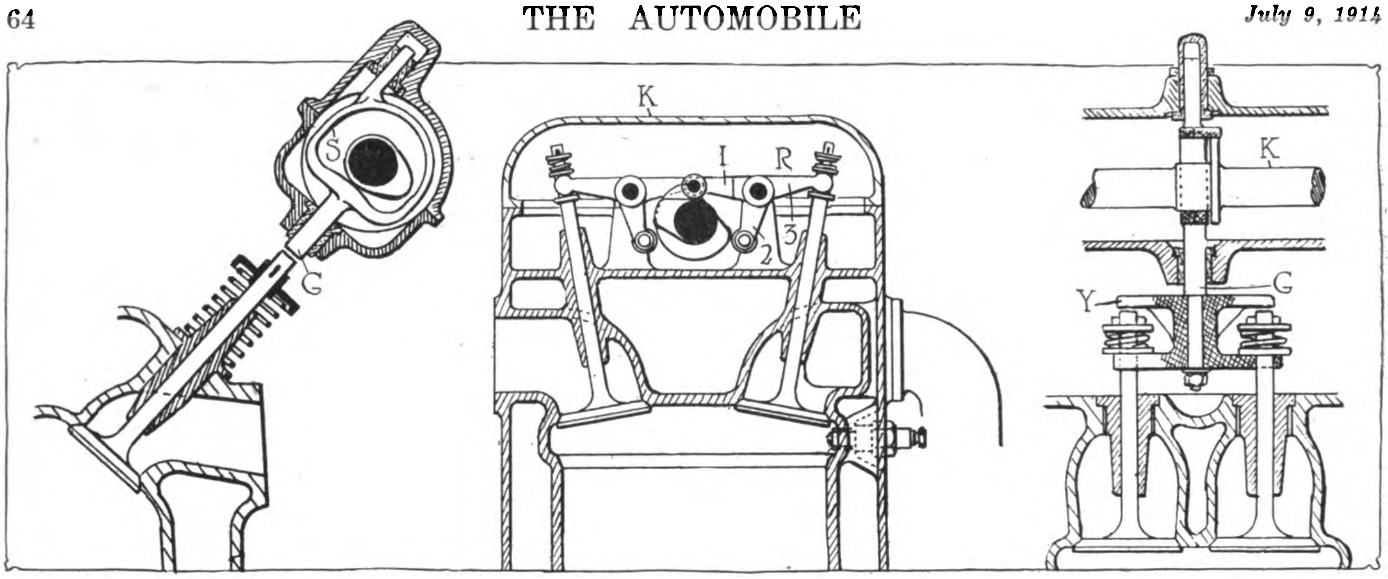


Fig. 1—Left—Peugeot valve arrangement, sixteen inclined valves with direct cam operation for motor head camshaft. Same design is found on Sunbeam, Vauxhall and Nagant. Fig. 2—Center—Schneider, eight valves inclined, double cam. No springs. Fig. 3—Right—Delage, showing pair of valves positively operated without springs

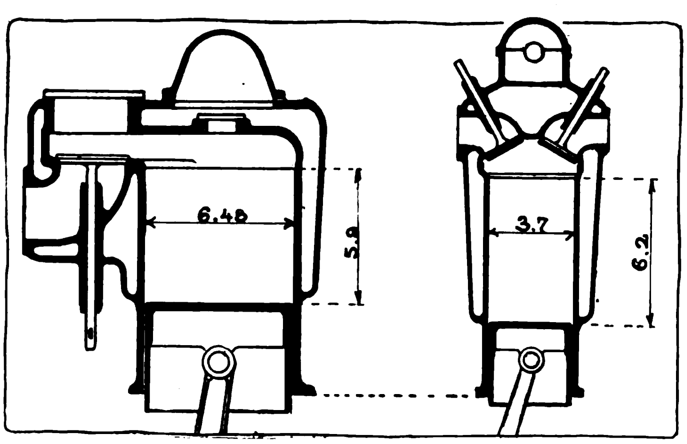
overhead type. Examples are Sunbeam, Vauxhall and Alda.

The ever-increasing question of motor speed has demanded greater attention to valves, and this has been particularly necessary this year with the piston displacement reduced to 274.6 cubic inches. The average crankshaft speed in a race may be put down at 2,600 to 2,700 revolutions per minute. Not a few motors will run at 3,000 revolutions per minute and over, and it is quite the exception to find motors to run below 2,500 revolutions per minute.

Peugeot Valve Scheme

These high speeds have caused prolific valve troubles as well as troubles with the valve-operating gear. Either valves refused to operate correctly above a certain speed, or the heavy springs employed to secure a quick seating of the valve wore away the cam. The type of valve-operating gear which the Peugeot used has found considerable following. This provides practically a direct operating cam, there being two overhead camshafts, each inclosed in an independent aluminum housing and located nearly above the valve stems. The two camshafts are driven by a single train of spur gears. Fig. 1 shows the Peugeot scheme, the cam operating in what may be termed a stirrup S, having a couple of projections to serve as guides. The lower of these guides G is in direct contact with the valve stem. This piece is unusually light and is the only intermediary between the cam and the valve. Peugeot designed its type of valve mechanism and used it in last year's race and has continued it this year. It appears in general design on Sunbeam, Vauxhall, and Nagant.



Left—Winning motor 1906. 778 cubic inches, 1200 r.p.m., 105 horsepower, 90 m.p.h. Right—Winning motor 1914. 274.6 cubic inches, 3000 r.p.m., 130 horsepower, 108 m.p.h.

Delage in his latest type of valve gear has abolished valve springs entirely, each of the sixteen valves being positively opened and positively closed. Figs. 3 and 4 show a section of the cylinder head of the Delage with a valve mounted at approximately 45 degrees and using two camshafts mounted in line with the valve stem. There are sixteen valves and the camshafts are driven by bevel gearing through a vertical shaft and set of bevel gears, all being inclosed in oil-tight aluminum cases. In order to give additional rigidity to the overhead structure the two camshaft housings are united at the rear by an aluminum cross-member.

Valve springs are not used, that is to say, springs are not relied upon primarily to bring the valves back to their seats. The cam operates within the stirrup-shaped member S, with its two projecting stands, one outward and the other G towards the valve stem, where it passes into and is securely attached to a very light double-yoke Y. The valve stems for the two intake or exhaust valves for each cylinder are received in this yoke, and as the yoke has a positive reciprocating motion it opens the valves on the downward movement and closes them on the return. There is a very light coil spring on each valve stem between the arms of the yoke, but this spring is in no way responsible for the return of the valve, but merely serves to secure the final seating of the valve, in view of the clearance which must be left between the push member and the valve stem.

Schneider Without Valve Springs

The Schneider like the Delage has abolished valve springs, making use of double cams, Fig. 2, which give a positive return or closing movement to the valve. There are only two valves per cylinder and these are inclined but 10 degrees from the vertical. They are operated by a single camshaft driven by an inclosed train of spur pinions at the front of the motor. The rocker arm R for each valve has three arms, designated respectively 1, 2 and 3. The double cams operate on arms 1 and 2 to respectively open and close the valve and the arm 3 has a yoke N which spans the valve stem and operates between collars on the stem. The entire valve mechanism is compactly hidden under a single aluminum cover K which completely encases the top of the motor. The spark plugs are located on the side just below the intake valve.

Alda Has Hollow Camshaft

In the Alda motor the sixteen valves are inclined at an angle of approximately 30 degrees to the vertical and are operated by a single hollow camshaft carried in plain bearings in a separate compartment of the cylinder head. There is a separate rocker arm for each valve, this rocker arm having a roller on the inner end where it bears on the cam and another on the outer end where it bears on the valve stem. An aluminum cover extending the full length of the motor incloses the entire valve mechanism. The camshaft is driven by a train of spur pinions in front.

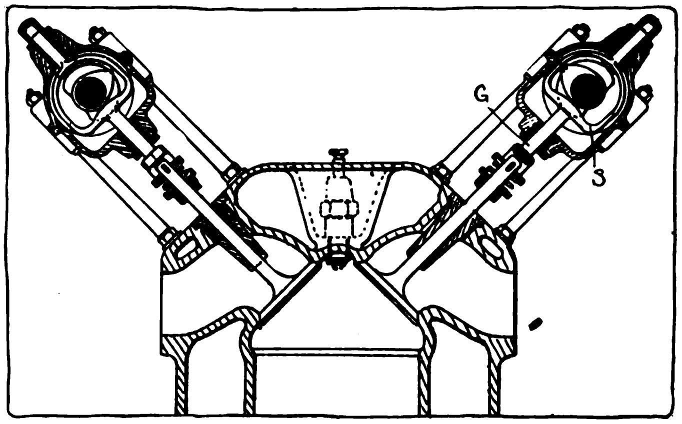


Fig. 4—Delage arrangement with sixteen inclined overhead valves operated by cams.

Opel's Overhead Valves

The overhead valve mechanism of the Opel with its sixteen inclined valves is much similar to that on the Alda, excepting that the valve springs are not inclosed, although the camshaft is encased in a compact compartment. The valves, Fig. 5, are inclined approximately 35 degrees from the vertical, and there is a rocker arm for each valve, the rocker arm having a roller on its inner end and an adjusting screw on the outer end where it bears on the valve stem. The camshaft is driven from the rear by a vertical shaft with double gearing.

Fiat's High-Speed Début

This is the first year that Fiat has come out with a small high-speed racing motor, having heretofore been an exponent of large type power plants. Double intakes and exhausts are used in each cylinder and these are mounted at approximately 40 degrees from the vertical and are operated by a single camshaft, Fig. 7, mounted centrally in a compartment over the cylinder head. There is a separate rocker arm for each valve and the camshaft actuates these rocker arms through vertical push rods, or plungers P with rollers on their lower end contacting with the cams. Each rocker arm carries an adjustment on its inner end and an arch-shaped outer end for contacting with the valve stem. Camshaft is supported in a hollow of the cylinder head which takes a steel covering, this cover carrying the plungers for the rocker arms.

The Silent Mercedes

Evidently the Mercedes men are sworn to absolute silence for it is impossible to get from them any statement regarding their cars. In general the motors used in all five are alike, and are similar to the aviation type used a year ago. They use separate steel cylinders which are forgings, not castings, and are turned from the solid stock. To these the aluminum jackets are autogenously welded. There are sixteen overhead valves, four per cylinder, operated through rocker arms from a single camshaft. Two Bosch double magnetos are used, thus giving four synchronized sparks per cylinder. The cylinders are 93 x 165 mm. which is 3.6 by 6.4 inches bore and stroke. The crankshaft is carried on five plain bearings, the gearset gives four speeds with direct and fourth, and a cone clutch is used.

The cars have that type of streamline body developed a year ago and use a V-type radiator. The spare wire wheels are carried in a rear compartment instead of being strapped on, the streamline effect of the body being carried out in this.

The new Peugeot racers have more external changes than internal features, as the engineers responsible for them have been content to carry out last year's design with reduction in cylinder size to meet the new rules. No essential modifications have been made in the motor, and the gearbox and the rear axle are the same with the exception of ratio. Externally the cars are much lower than formerly owing to the front springs being under the axle.

Latest Peugeot Design

From the question of streamline body design these cars are the finest entered in the race. The radiator is narrow and of W-cross section although this cannot be noticed by the casual observer as the wire guard is set in the radiator frame, and its V-form might be mistaken for the radiator itself.

The bonnet, with the usual hand-hole for reaching the carbureter is continued rearward by a scuttle dash nearly up to the height of the steering wheel. A streamline tail is used which entirely encases the gasoline tank and the spare wheels. There is a hump on the top of the tail and a similar one on the base of it to accommodate the wheels. The whole of the rear portion of the body back of the tank forms a hinged cover with an eyebolt set in the extremity so that the mechanism can open the lid, thus exposing the tires while the car is being brought to a standstill. Even the under pan has received close attention and narrows as it extends rearward so that it just encases the driveshaft and forms a continuation of the tail broken only enough to allow the passage of the axle.

Braking is done on all four wheels, there being internal expanding bands operating in ribbed drums. In addition the usual brake is carried on the rear of the gearbox.

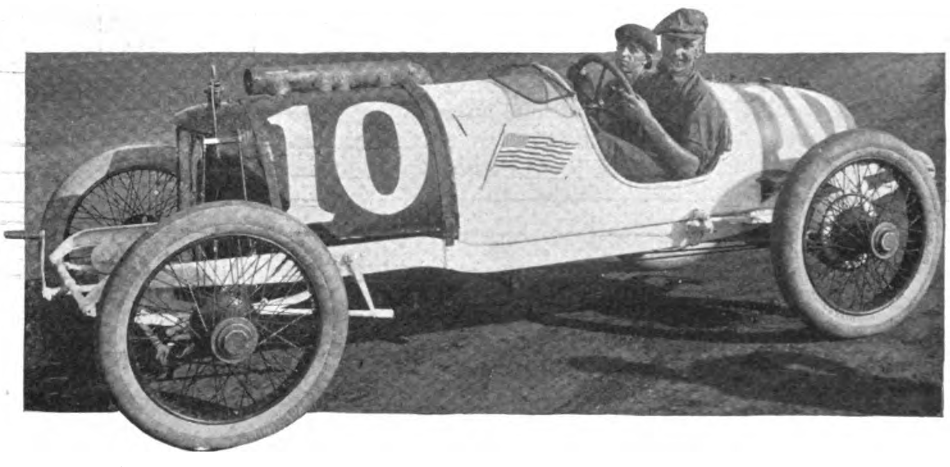
Gray Fox	Wilcox	63.8
Braender Bull Dog	Chandler	Running at Finish
White	Shrunk	Running at Finish
Chalmers	Wetmore	Running at Finish



Rickenbacher, in the Duesenberg, who won the Sioux City 300-mile race

SIOUX CITY, IA., July 4—The State of Iowa has made good today. Rickenbacher, driving an Iowa car, the Duesenberg, today won the 300-mile race on the Speedway at this city, averaging 78.6 miles per hour, and leading Spencer Wishart in a Mercer by the narrow margin of 48 seconds for the three centuries on the new 2-mile dirt oval, otherwise known as the Sioux City Speedway.

Although but seventeen of the twenty-two cars came to the starting line, today's race was one of the greatest interest, and until the 200-mile point was reached it was anybody's race. Rickenbacher, the winner, was not in the lead until at 180 miles, at which point the race had practically settled down, and it was apparent that the remaining 100 miles would be a duel between Rickenbacher and Wishart.

Frequent Position Changes

Rarely in a speedway race has there been such change of positions in the first 200 miles. Burman, driving a Peugeot, which Jules Goux piloted at the recent Indianapolis meet, jumped to the front at the opening of the race and held the lead until 33 miles, when Wishart put his Mercedes to the fore, and Rickenbacher was working up into third place. At 80 miles Wishart and Rickenbacher were practically tied for first place, and they ran neck-and-neck to the 100-mile post.

At 120 miles Tom Alley, driving another Duesenberg, was leading with Wishart second and Rickenbacher third.

At 140 miles there was another shift in position, Wishart taking the lead with Rickenbacher second and Alley third.

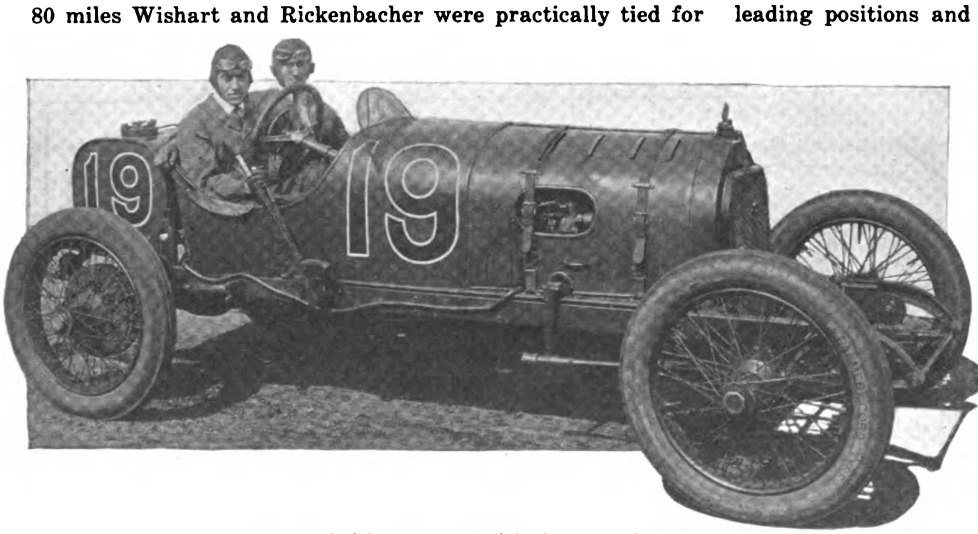
There was still another shift at 160 miles, when Knipper, driving the Thomas Delage which won at Indianapolis, was in first position with Patschke in the Marmon second, Rickenbacher third and Wishart fourth.

Rickenbacher Takes Lead

When 20 miles more were covered, there was still another shift, Rickenbacher getting into the lead. At 200 miles the Delage was disposed of through a cracked jacket, the Marmon was delayed by carbureter trouble, and Rickenbacher had a slight lead on Wishart.

Although seventeen cars started, seven actually finished the race, and three others running at that time were flagged off.

Today has been a sad one for the foreign cars, six of which were entered and handled by American pilots, and only one of which finished. The day's results are in strong contrast with May 30 at Indianapolis when foreigners carried off the four leading positions and America was content with fifth place.



Spencer Wishart, who finished second in the Mercer

In today's race of three Peugeots, two Sunbeams and the Thomas-Delage entry, only one, the Delage, finished. All of the others went out through mechanical troubles. Burman's Peugeot was out at 160 miles with broken crankcase, connecting-rod and piston. Stringer, in another Peugeot, was out at 172 miles with a broken connecting-rod. Mulford, driving the third Peugeot, was out at 30 miles with a broken oil tank. Both Sunbeams were out before the finish, Grant at 262 miles with a broken universal, and Babcock at 200 miles with water troubles.

Knipper, although in the lead at 160 miles, met his fate at 196 miles, when the jacket of No. 4 cylinder was cracked and he had to stop every 10 miles thereafter to take on water.

But there were more upsets in favorites today than those that fell to the lot of the foreigners. Oldfield, the American hero at Indianapolis, was out at 146 miles, with a cracked cylinder. There were one or two local entries, notably the White and Chalmers, which had serious trouble early in the race, the White with bearings, and the Chalmers with valve and carbureter difficulties.

Duesenberg driven by Alley and Mulford, which took third place

The race started at 11 o'clock. There had been three cars which had failed to qualify by averaging 70 miles an hour—the two Chevrolets and the Moon. The Metropol was out with a broken crankshaft and the Stafford with a broken crankcase.

At the outset it looked as if the race would be a runaway for Burman in the Peugeot. He made his bid right at the outset. Being in the first row of starters he soon jumped away from Anderson and Mason and swung by the tape for the first time with a fairly comfortable lead. The second time around saw this increased to almost a half mile, for as he crossed the tape the closest to him was Anderson in the Stutz, who also had opened up on the others, leading Wishart by a few car lengths, while trailing were Mulford, Shrunk, Oldfield, Knipper, Patschke, Stringer, Mason, Grant, Wilcox, Babcock, Alley and Chandler, strung out for a mile. At this point Mason had to stop.

Burman Takes Lead

Burman, once out in front, settled down to a steady grind, while Wishart became runner-up, leading Mulford by about 100 yards. Anderson, Oldfield and Patschke were in the next group, while the others were well spread out, with Chandler bringing up the rear. Burman had the satisfaction of leading at the first 20-mile post, but Wishart had been sticking to his task and he was gradually eating up the distance that separated him from Burman. The Peugeot driver apparently was not getting as much speed out of his mount as he had at the outset. It was noted that there was a miss on the Peugeot that slowed it, and the Mercer took advantage of this and Wishart caught his man when Burman stopped in the thirty-second mile to change a tire and to make a carbureter adjustment.

Wishart was the leader at 40 miles with Stringer runner-up and Rickenbacher in third place. Grant was fourth and Patschke fifth. The Mercer star also led at 60 miles, but Rickenbacher had gone to second and Anderson to third. There were only 17 seconds between first and second, however. At 80 miles Wishart and Rickenbacher were tied and Alley in the other Duesenberg was third, with Anderson fourth. The same order prevailed at 100 miles, with Wishart being just 1 second to the good.

Tom Alley, who has been Ralph DePalma's mechanic for several years and who was given his first chance as a driver when No. 12 Duesenberg was turned over to him, had the joy of leading this field at 120 miles, with Wishart second and Rickenbacher third. Wishart got to the front again, however, at 140 miles, with Rickenbacher still sticking to him and Alley back in third place. The next 20 miles, though, saw a general shaking up among the leaders. Knipper, in the Delage, who had been running fourth for 40 miles, went into the lead, with Patschke second, Rickenbacher third and Wishart fourth.

At 180 miles Rickenbacher climbed out in front, and

The Sioux City Speedway before the start of the 300-mile race, held July 4, showing arrangement of the grandstands

once there he never relinquished his advantage. Knipper was back to second, but at 200 miles Wishart had ousted him, and from there on to the end it was a duel between the Rickenbacher-Duesenberg and the Wishart-Mercer. The two pulled away from their rivals and each was waiting for something to happen to the other fellow. Rickenbacher's knowledge of the track, where he has raced for the last 2 years, stood him in great stead and the way he took the turns picked up many seconds for him. Both men were in the same lap when Starter Fred Wagner took his collection of flags across the track. Rickenbacher got the checkered bunting first, then had to go two more laps to play safe on the scoring.

Duesenberg Gets Third

With the two leaders out of the way, the balance of the field settled down to fight for the rest of the prize money. No. 12 Duesenberg, the Anderson-Stutz and the Patschke-Marmon were running so closely that any one of them might have landed third, but the Duesenberg was the one to gain the position, and back of it were the Stutz and Marmon in the order named. Then there was a long wait until Knipper and Wilcox could finish. They were far in the rear and back of them were the White and the Chalmers, all striving to finish because there were ten prizes. The officials waited on Knipper and Wilcox, but the other three were so far behind that in kindness to both the drivers and the spectators the officials flagged them.

The ten prizes were awarded as follows: Rickenbacher, $10,000; Wishart, $5,000; Alley-Mulford, $2,500; Patschke, $1,750; Anderson, $1,500; Knipper, $1,100; Wilcox, $900; Chandler, $800; Shrunk, $750; Wetmore, $700.

That Rickenbacher should have won this gruelling grind is not surprising when one reviews his record. He has driven in more races on the Sioux City track than any other man; he has broken several records there, including the 50-mile mark; he had a car that is surprisingly fast and built for just this sort of work, while his knowledge of the speedway gave him a great advantage. In addition, Rickenbacher had comparatively little trouble, making only two stops in the 300 miles. His first one was at 144 miles when he lost 35 seconds changing a tire; again at 254 miles he stopped at the pits.

While there were no accidents during the race, still there were several drivers injured by being struck by flying clods of dirt. It seems to be a peculiarity of this track, and Referee Kneedler, realizing it, forced every pilot to equip his car with a wire screen, placed at the steering wheel.

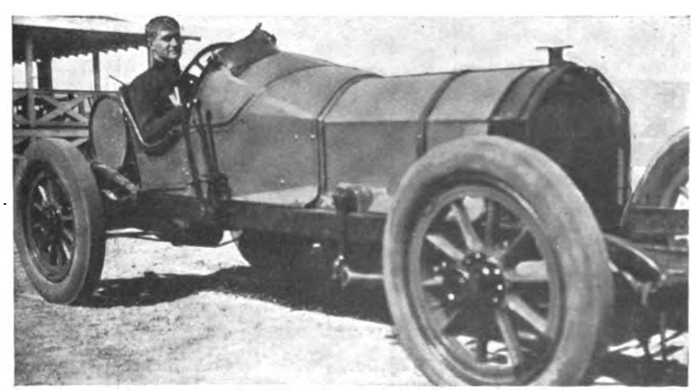
The two Duesenbergs that came in first and third have 4.4 by 6-inch motors, the piston displacement being 360.5 cubic inches. The wheelbase is 106 inches. Rudge-Whitworth wire wheels with Riverside tires were used. Thirty-three by 4.5-inch tires were used on the front and 35 by 5 on the rear. Ignition was supplied by a Bosch and the spark plugs were K. L. Gs. The carbureter was a Schebler and the gear ratio is 2.6 to 1. Oilzum oil was used.

The car to finish second, which was Spencer Wishart's Mercer, was equipped with a 4.8 by 6.2-inch motor having a displacement of 445 cubic inches. Both magneto and plugs were Bosch made and a Rayfield carbureter was fitted. The wheelbase is 112 inches, the gear ratio 2.5 to 1. Rudge-Whitworth wheels with Palmer tires, 35 by 5 inches all around were employed. Castor oil was used for lubrication.

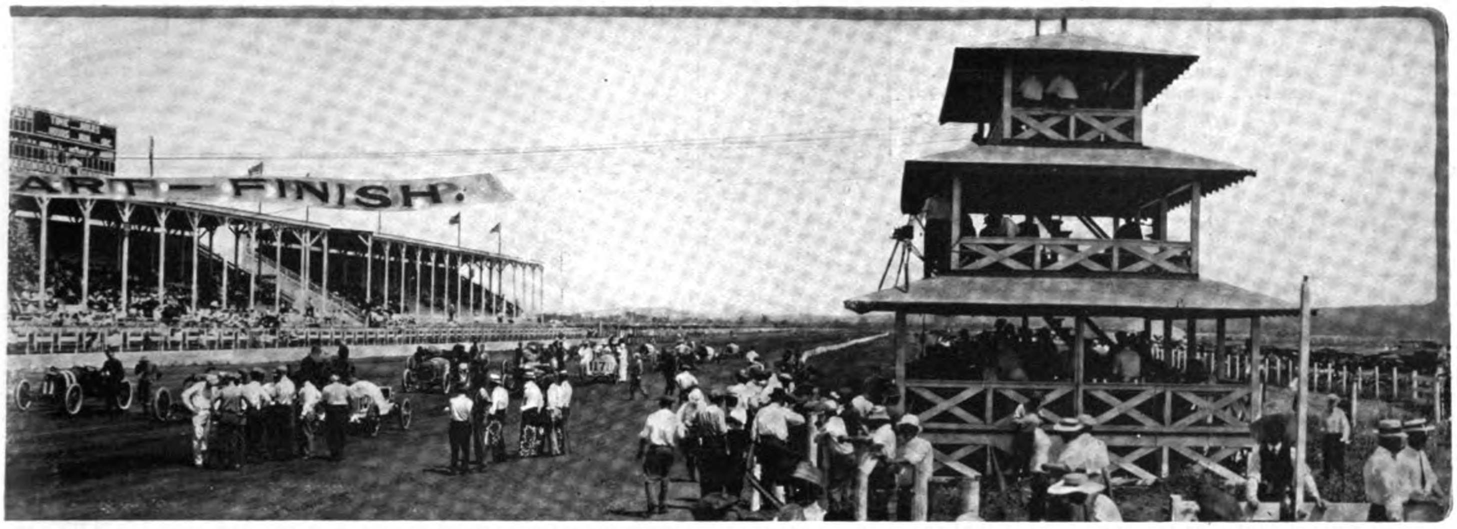
Complete specifications of all the cars will be found on page 104.

The track, though, stood up wonderfully. It had been predicted that it would be cut to pieces before 200 miles, but outside of a few rough spots on the turns it looked as good at the finish as it did at the start. It had been so well oiled that there was no dust and the speed of the big oval was shown by the fact that Rickenbacher averaged 78.6 miles per hour for the 300 miles.

So encouraged are they by the results of their efforts that they have decided to have a real speedway before another year is past. They propose to either resurface the present track or let the present gumbo stay and bank the turns so they will permit of greater speed. To get the flyers they intend hanging up a $50,000 purse and to retain the same day they had this year—the national holiday. At the present time they are handicapped by lack of really good transportation between the City of Sioux City and the track, which is located just over the state line in Union County, S. D.



Patschke in the Marmon, who was awarded fourth prize



at the start and finish line. The officials propose to resurface the present track and to hang up a $50,000 purse for 1915

Right Rear Tires Most Trouble

SIOUX CITY, IA., July 4—If right rear tires could have been eliminated from today's race the winning pace of 78.6 miles per hour would have been considerably exceeded. Every car that changed a tire changed the right rear, and five of the drivers had to change two right rears.

Next to tire troubles there came many examples of general breaking of car parts, which seemed to prove that after a racing car has been through two or three gruelling tests it must be rebuilt to give satisfaction. For example, Knipper, driving the winning Delage from Indianapolis, cracked a waterjacket after he had driven 200 miles. Oldfield, driving a Stutz, was out with a cracked cylinder at 144 miles. Burman, in one of the Indianapolis Peugeots was out at 160 miles with a broken crankcase, connecting-rod and piston, undoubtedly due to the seizing of a bearing. Stringer, driving another Peugeot, broke a connecting-rod at 172 miles. Mulford, in a third Peugeot, was out at less than 30 miles with a broken oil tank and other oiling trouble. Grant's Sunbeam, which behaved so admirably at Indianapolis, was out at 262 miles with a broken universal. One of the Masons broke a drive-shaft at 4 miles, and Babcock, driving the other Sunbeam, had a hose connection burst at 200 miles.

Many of these troubles can be traced directly to the severe punishment that the cars have previously received.

Rickenbacher made two stops during the race with a total loss of time of 1 minute and 3 seconds. He changed the right rear at 144 miles, doing the work in 35 seconds, and at 254 miles he stopped for gasoline and oil, consuming 28 seconds in taking these on. Spencer Wishart made three stops with his Mercer. At 150 miles he took on gasoline and oil in 40 seconds; at 196 miles he took 8 minutes changing a broken valve spring and at 260 miles he blew a right rear and took 50 seconds for the replacement.

Tom Alley, who brought No. 12 Duesenberg into third place, had a narrow escape from severe injury when he made his first stop at the end of the 78th lap. The car was filled with water and oil and as soon as the pit man started to fill the tank with gasoline the car caught fire and a merry blaze continued for about 15 seconds and was extinguished with three Pyrene extinguishers.

While Mulford held the wheel he made but one stop, at 208 miles, for oil and water and to change a right rear tire which had blown out.

Short Stops at Pits

Anderson stopped twice during the race, having a total delay of 3 minutes and 9 seconds. First he took on gasoline and oil and at 224 miles changed the right rear, and replenished with gasoline. He had no mechanical troubles.

Patschke had a total loss of 4 minutes at the pits with his Marmon, having to make four stops. At 12 miles he took on gasoline and oil. At 178 he changed a right rear. At 256 he stopped for carbureter adjustment and to take on water, and at 294 miles he was compelled to stop again for water.

Knipper, driving the Delage which won the Indianapolis race, had eleven stops, totaling 19 minutes and 15 seconds. His trouble started at 198 miles, when No. 4 cylinder cracked, allowing the water to run out. He decided to continue and stop frequently to add water. After changing the right rear tire and changing a spark plug in No. 4 cylinder, he was started after a delay of 10 minutes. He stopped for water at 214, 222, 232, 242, 252, 260, 268, 270 and 280 miles.

Wilcox drove the Gray Fox the last 10 miles without oil, doing this to finish in seventh place, although he had sufficient leeway to finish seventh and stop for oil. His first stop was made at 100 miles for oil and water; his second was at 116 miles for gasoline, oil and water. He made a long stop a few laps later to change 3 valves and later had push-rod trouble, causing 3 delays at the pits. A push-rod broke at 238 miles, and there was more valve trouble at 260 miles.

Five stops had to be made by Chandler in the Braender Bull Dog, the total time being 1 hour 39 minutes 3 seconds. The longest was at 80 miles, when the oil line broke, and after being repaired it gave much trouble, necessitating stops at 100, 122 and 130 miles. At each of these the line was

Stutz and Maxwell Star at Tacoma

Former Wins 250 and Latter 200-Mile Event—100-Mile Race Won by Frantz Special

TACOMA, WASH., July 4—*Special Telegram*—The 2-day racing on the 2-mile Tacoma Speedway yesterday and to-day evolved three popular winners in the three races scheduled for the Montamara speed carnival, Cooper in a Stutz winning the 250-mile event, Hughes in a Maxwell the 200-mile one, and Parsons in a Frantz the 100-mile race.

Earl Cooper, driving a Stutz, won the 250-mile race to-day for the Montamarathon trophy, averaging 73.44 miles per hour and defeating his nearest challenger Ruckstall, in a Mercer, by 12 miles. Cooper's time was 3:24:34 4-5 seconds. There were five other finishers, the Ruckstall Mercer, second, averaging 70.57 miles per hour. Klein, driving the King, third, averaging 69.89; Parsons, driving the Frantz, with an average of 66.57; and Taylor in an Alco, fifth, averaging 64.8. Nine other cars started, making a total of fourteen, and of these only one was running at the finish, this being the Hupmobile, which was flagged off when the race was called.

Cooper Breaks Records

Cooper, the meteor of the speed constellation who in 1913 won the American championship through his consistent driving on the coast, never before shone so brightly as he did to-day in the race for the Montamarathon trophy. Lying back he shot the Stutz to the front after covering 84 miles and was never headed thereafter. His victory was decisive.

With Cooper so far in front, interest in the race centered in the battle for second place between Ruckstall, the Mercer pilot; Klein, the King driver; and Dingley, at the wheel of the Ono. Until Dingley's car was wrecked at 248 miles he had a slight advantage on the other two contenders as he was leading them by half a lap. With the Ono eliminated, the fight for second money narrowed down to a last lap spurt between the Mercer and King, and the Mercer got the decision by 2 minutes.

Six cars that were nominated failed to appear when the field was sent away at 2 o'clock—the Romano, Chalmers, P. C. Special, Hudson, Italia and de Alene's Marmon. With the exception of the Marmon, which was wrecked in the Potlatch race of yesterday, no reason was given for the withdrawal of these entries.

Maxwells Dangerous Contenders

Seven of the starters suffered mechanical trouble. All three Maxwells were eliminated before Cooper got the checkered flag, although two of them were in dangerous positions for the greater part of the race. Hughes, one of the Maxwell team, was overcome with the heat and was relieved by Carlson who completed 103 laps before he was forced to withdraw his mount with a broken valve spring. Tetzlaff's Maxwell was a contender for 90 laps when it suffered a broken steering gear. Teddy crawled up to the pits with his mechanician, Benedict, astride the hood and holding the parts together.

Brock's Ray also looked dangerous and showed a world of speed until it was eliminated on the eighty-fourth lap with a broken frame. The two Fiats, driven by Verbeck and Sorrell, were the first to give up the chase, Sorrell driving but three laps and Verbeck withdrawing after making thirteen circuits of the course.

Intercity Trophy Race 100 Miles

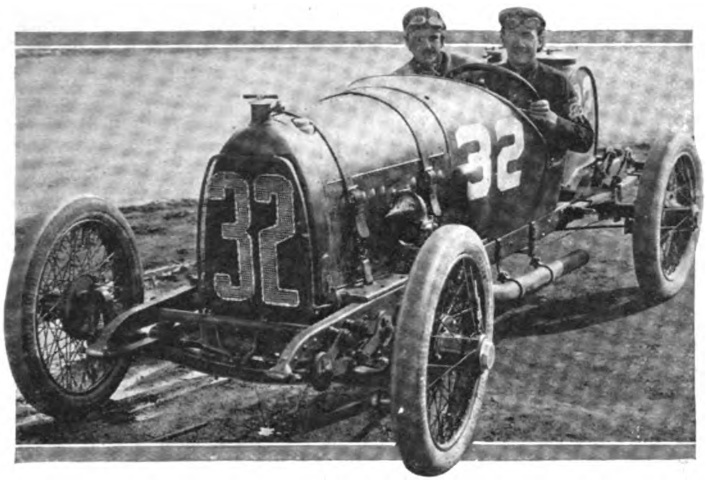
Position	Car	Driver	Time	M.P.H.
1	Frantz,	Parsons	1:21:29 2-5	73.6
2	Ray,	Brock	1:31:22 2-5	65.72
3	Lozier,	Latta	1:32:33 1-5	64 8
4	Studebaker,	Staley	1:39:37 2-5	60.23
5	Chevrolet,	Croston	———	——
6	Hupmobile,	Smyley	———	——
	Mercer,	Thomas, out on 34th lap with burned-out bearing.		
	Romano,	Barnes, out on 31st lap with broken air line.		
	P. C. Special,	Terrien, out on 13th lap, engine trouble.		
	Hudson,	Schneider, out on 9th lap with broken crankcase.		
	National,	McGoldrick, out on 7th lap with burned-out clutch.		

Potlatch Trophy Race 200 Miles

Position	Car	Driver	Time	M.P.H.
1	Maxwell,	Hughes	2:41:32 2-5	74.28
2	King,	Klein	2:41:36 4-5	74.25
3	Stutz,	Cooper	2:44:01 2-5	73.26
4	Ono,	Dingley	2:50:13 3-5	71.81
5	Mercer,	Ruckstall	———	——
6	Frantz,	Parsons	———	——
	Marmon,	DeAlene, out on 73rd lap, car wrecked		
	Chalmers,	Kennedy, out on 33rd lap with broken spring hanger.		
	Mercer,	Pullen, out on 24th lap with broken rear axle shaft.		
	Maxwell,	Tetzlaff, out on 17th lap with broken valve spring.		
	Ray,	Brock, out on 11th lap with bent rear axle.		
	Maxwell,	Carlson, out, engine trouble.		
	Fiat,	Verbeck, out, engine trouble.		
	Italia,	Welch, out with two cracked cylinders.		

Yesterday, the festival opened with two curtain-raiser events, one at 100 miles for cars of 450 cubic inches and under, in what was known as the Inter-City Century. This was won by Parsons driving a Frantz, who drove the Century in 1 hour, 21 minutes, 29 2-5 seconds, averaging 73.6 miles per hour for the distance. By his victory Parsons repeated his triumph of last year and got permanent possession of the Perpetual Challenge Trophy presented by the Tacoma Automobile Club, as well as $750 in cash.

In this race there were eleven starters, four of which finished the distance, two others were running at the finish, and five withdrew for mechanical troubles during the race.



Hughes at wheel of his Maxwell

Brock, in the Ray, was second, almost 10 minutes behind the victor. Latta, driving a Lozier 100 miles without a single stop for tires or fuel, was a close third. Staley, in a Studebaker, was fourth, and Croston's Chevrolet was fifth. The Chevrolet also completed the entire century without a stop. The only other car to finish was Smyley's Hupmobile, which took sixth money.

The Intercity race was a battle between Parsons and Brock which reached its height in the last 40 miles. Near the finish the Ray suffered from rear axle trouble.

Hughes Wins Potlatch

The major event on yesterday's program was for the Golden Potlatch trophy for cars not exceeding 600 cubic inches, the distance being 200 miles. Hughey Hughes in a Maxwell was winner, after a sensational struggle with Arthur Klein in the King, and finally won by the scant margin of 4 2-5 seconds. Hughes' time was 2 hours 41 minutes 32 2-5 seconds, and Kleins' time 2 hours 41 minutes 36 4-5 seconds.

Montamarathon Trophy Race 250 Miles

Position	Car	Driver	Time	M.P.H.
1	Stutz,	Cooper	3:24:34 4-5	73.44
2	Mercer,	Ruckstall	3:32:33 4-5	70.57
3	King,	Klein	3:34:22 1-5	69.89
4	Frantz,	Parsons	3:45:20 1-5	66.57
5	Alco,	Taylor	4:17:12	64.8
	Hupmobile,	Smyley, running when race was called.		
	Ono,	Dingley, out on 124th lap when car overturned.		
	Maxwell,	Hughes-Carlson, out on 103rd lap with broken valve spring.		
	Maxwell,	Tetzlaff, out on 90th lap with broken steering gear.		
	Ray,	Brock, out on 84th lap with broken frame.		
	Mercer,	Pullen, out on 27th lap with broken axle shaft.		
	Fiat,	Verbeck, withdrew after completing 13 laps.		
	Fiat,	Sorrell, out on 3rd lap with broken air line.		
	Maxwell,	Carlson, out, engine trouble.		

Hughes averaged 74.28 miles per hour. By his victory Hughes gets possession of the Challenge Trophy and $1500.

Hughes took the race by a garrison finish. The triumphant Maxwell shattered Earl Cooper's record of 71.07 miles an hour established in the 1913 event.

At the finish, Cooper was almost as close to Klein as the King driver was to Hughes and was a close third. Dingley's Ono was fourth, Ruckstall's Mercer fifth and Parsons' Frantz sixth.

Until it was eliminated on the seventy-third lap, de Alene's Marmon was showing the way to the field. It went to the front at the end of the twenty-third lap and was in front for 100 miles, having an advantage of two laps when it blew a tire and rolled over in the ditch. Cooper then assumed the role of pacemaker and was not overtaken until the ninety-eighth lap when Hughes thundered by the Stutz. On the ninety-ninth lap, seconds only separated the Maxwell, Stutz and King. When almost on top of Hughes, Cooper blew a rear tire and this misfortune gave the Maxwell the race and the King second money.

Ed. Pullen, winner of the 1914 grand prize, failed to finish, but to him go the honors for driving the fastest lap. Pullen sent the Mercer around the 2-mile course in 1 minute 22 2-5 seconds, an average speed of 87 miles per hour.

35,000 People at the Races

Speed fans of the northwest turned out in throngs to witness the races. Twenty thousand people were attracted to the speedway yesterday and the holiday crowd that packed the stands today numbered 35,000.

Two accidents marred the 2 days of exciting sport. In today's race, Bert Dingley at the wheel of the Ono and his mechanician, Swanson, were injured when on the next to the last lap, the car plunged from the course and threw its occupants 60 feet before overturning in a ditch. Both were severely injured and it was announced tonight that Dingley is not expected to survive.

In the Potlatch trophy event of yesterday, de Alene, the Marmon driver, and his helper, Scanlon, were hurt.

A brush between Hughes and Carlson in Maxwells

Development of Automobile Trade Abroad

Good Sale for Low-Priced Cars—Latest Consular Report Gives Suggestions to Exporters—Our Cars Popular

THE Department of Commerce and Labor has issued the third special consular report in the form of a supplement to that issued last year and which appeared in THE AUTOMOBILE for May 1. The first of these publications appeared in this magazine in August 22, 1912.

American exporters of automobiles have made an excellent start in many foreign markets and as a rule occupy a good position wherever there is an extensive sale of cars.

Fourteen consuls general, comprising the local supervising officers in the district of Europe, covering all of Europe except European Russia, the Balkan States, and Greece, have rendered to the U. S. headquarters a series of statements showing what has been done in their respective countries to extend the American export trade in automobiles.

These reports are of great interest as they give exceptional value to the American manufacturer who wishes to obtain accurate information relative to the conditions of trade and other requirements of contemplated fields for the exploitation of his product.

Cyclecar in United Kingdom

In the United Kingdom, one of the chief foreign markets for low-priced American automobiles, the most prominent feature of the trade at present is the development of the cyclecar, which is considered an important competitor of the less expensive automobile. It is shown that Europeans in general will buy low-priced cars if the cars are properly exploited, regardless of local conditions. It is essential that the exporter show a real economy in operation of his car, because of the higher price of gasoline in Europe. Attention to this item has already yielded large results to the Americans who are now putting large numbers of cars on the Continent.

There is a wide sale of American cars in England. The excellence of the construction of the American car has been widely and generously acknowledged. While there are some British cars selling at about the same or even slightly lower prices, the introduction of the low-priced car was due to American initiative, and American manufacturers have not spared expense in judicious advertising and in demonstrating the real value of their product. As a result, the low-priced British cars are not as widely known as those of American manufacture.

It is characteristic of the English buyer to purchase an automobile which he expects to use for a long time, so that durability is one of the considerations that influence him most strongly. The slightest deterioration in the quality of a single American make which is sold to any extent abroad will not only affect the particular manufacturer disastrously but will cause definite injury to the prestige of all American manufacturers selling automobiles in foreign countries.

There is only one point that the American car lacks and that is finish. There are a large number of English automobilists who are willing to make an additional outlay of $100 to $250 for an American car if they can obtain a car that satisfies their requirements in the way of finish. Such purchasers are now either buying British cars, at an extra cost of perhaps 25 to 50 per cent., or else are adapting a British body to an American chassis.

British Make 200 Types of Machines

The sixty firms in Great Britain manufacturing automobiles offer to the public nearly 200 types of machines. The total output is now probably well over 20,000, although exact figures are not easily obtainable. It is calculated that two-thirds of the home demand is supplied by the British automobile manufacturers. German and Italian cars are increasing their hold in England, but French imports have dropped almost $2,500,000 in the last 4 years.

Official records show that in November, 1912, there were registered in France 76,771 automobiles, an increase of 12,562 since the same date in 1911. The value of the automobiles imported into France from this country in 1911 and 1912 was respectively $416,687 and $871,685.

According to official statistics, the value of the automobiles imported into France from the rest of the world in the 3 years, 1909, 1910 and 1911, was respectively $1,453,483, $1,677,556 and $2,235,230. In 1912 the imports amounted to $2,738,035. The increase in 1911 was due almost wholly to the increased popularity of the moderate-priced American car.

Belgium Makes Many Bodies

It is estimated that there are more than 17,000 automobiles in use in Belgium. There are now twenty automobile factories in this country. This country does not seem to offer a very profitable field for the American manufacturer. The manufacture of automobile bodywork is an important industry in Belgium. The total annual production of the country is in the neighborhood of 3,650 cars, valued at nearly $6,176,000.

Spain Buys Small Cars

In this country cars of European manufacture, of 15 to 20 horsepower, Spanish rating, with closed bodies holding four people, and costing from $3,000 to $6,000 seem to be most in demand. There is at present absolutely no demand for medium or high-priced cars of American manufacture. There is a certain prejudice in the Spanish mind against being known as the owner of a cheap car, although the sale of American cars of this class is increasing rapidly.

One of the causes for the small market in cheap American cars is the big profit exacted by the local agent from purchasers which brings the selling price to almost double that asked by the agent in the United States.

Although France dominates the Spanish market the U. S. is becoming a keen competitor. As showing that there is a better market in Spain for the lower-priced automobile the import figures for the years 1910 and 1911 provide an interesting contrast. In the first of these years the total number of cars exported was 393 at a value of $739,230. For the following year the number of cars reached 612, but the actual value represented a decrease, the figure being $565,422. Imports from France into Spain during 1911 totalled $392,973, while those from the United States represented $68,723. The figures for 1912 are not yet available.

Russia Is a Growing Market

The Russian market for automobiles is increasing more rapidly than any other country in Europe for the reason that it has been backward up until very recent years and now there is a real demand for automobiles of all classes, particularly of the cheap but strong car.

There is a good market for American cars. Many American manufacturers have already arranged for agencies in the principal cities and are breaking down the prejudice that has existed against American cars for a number of years.

Italy Importing More American Cars

The first 11 months of 1912 showed continued increases in the sales in Naples of low-priced, well-made American automobiles of a good appearance. There are fifteen automobile manufacturers in this country with a total output in 1911 of nearly 5,000 pleasure automobiles and trucks. Although the 1912 output is not completed, from information recently gathered, it would appear that the output will show figures reaching at least 8,000 machines. For the 11 months ending November 30, 1912, there were imported into Italy 227 automobiles of American manufacture, as against 145 for the calendar year 1911, only 25 in 1910, and 7 in 1909. The American cars imported are practically all of the cheaper grades.

Argentina Buying Cars Fast

There have been 10,000 automobiles imported into Argentina since 1900. Demand has created supply, and today every class of automobiles can be obtained for hire. Eighty per cent. of the imports of automobiles for the first 5 years were of French manufacture. In 1911 the value of the American imports into this country were valued at $330,126. During the first 9 months of 1912 no less than 3,067 cars were imported, valued at $3,575,740. The U. S. imports during that period amounted to $392,917.

India

The increase of 37 per cent. in the importation of automobiles into India is one of the interesting features of the trade returns for the official year ended March 31, 1912. Bombay continues to be the principal port of entry; of the year's imports, amounting to $3,255,785, cars to the value of $1,668,099 were received here. The value of the imports from the United States were valued at $195,925, four times the amount of 1910-11. It puts the United States in the second place and shows that our manufacturers are taking a serious interest in the Indian market. Returns covering the 6 months April to September, 1912, show automobile imports amounting to $1,305,111, as against $980,111 for the corresponding period of 1911. While it is acknowledged that American manufacturers are able to sell low-priced cars of good quality in every detail of construction, the Bombay buying public is inclined to think that the American is not yet able to compete with the European manufacturer in the highest-grade models. It is claimed that if American agencies in high-grade cars were established, many sales could be made. The American car sold at prices up to $2,000 has won its way absolutely on its merits and with the assistance of very little advertising.

Prices of Various Foreign Cars

The following list shows the prices of various less expensive cars of Continental and British make with which American cars have to compete:

Description of Car	Horsepower	Price
AUSTRIAN		
Four cylinders, interior-driven coupé, bore 80 mm. (3.1 inches), stroke, 110 mm. (4.33 inches), four-speed gears	16-18	$2,798
GERMAN		
Four-cylinder, inclosed valves, leather clutch, four speeds and reverse, bevel drive, chassis only	12-20 15-25	1,582 2,190
Four cylinders, engines en bloc, inclosed valves, chassis inswept in front and upswept at back, fitted with long springs, chassis only	5-12	973
Same, with torpedo double phaeton	6-16	1,460
Same, limousine or landaulet	8-20	2,190
Four cylinders, engine 75 by 88, thermo-siphon cooling, four speeds and reverse, forced-feed lubrication by pump, multiple-disk clutch, tires 750 by 88 mm. (29.5 by 3.5 inches), chassis	10-16	1,073
FRENCH		
Torpedo two-seater, four speeds, with hood and screen	8	1,022
Same, with interior-driven coupé	8	1,192
Four cylinders, four speeds, worm drive, two-seater, torpedo body.	11	1,679
Same, chassis only	11	1,294
Complete torpedo body or two-seater with dickey seat behind, four speeds, hood and screen	11 14	1,460 1,752
Same, with standard body	16	1,874
Same, with five seats	16	1,995
Four cylinders, tour-seater torpedo, with hood, screen, all lamps, horn, etc.	12	1,606
Four cylinders, engine 65 mm. (2.5 inches) bore, trough lubrication, high-tension magneto, thermo-siphon, cylinders cast in one, chassis price	8-10	1,216
ITALIAN		
Polished chassis, mono-bloc engine, four speeds	15-20	1,776
Four cylinders, Captain fixed wire wheels with detachable rims, dynamo electric installation, auxiliary engine-starting magneto, horn and speedometer, chassis complete	30	2,677
BRITISH		
Two-seater, bore and stroke of engine 69 and 130 mm. (2.7 and 5.1 inches), with hood, wind screen, lamps and horn	10-12	1,095
Same, four-seater	10-12	1,240
Four cylinders, bore and stroke 80 and 140 mm. (3.1 and 5.5 inches), 9-foot wheel base, four speeds forward and reverse, four-seater, worm or bevel drive, with hood, screen, etc.	16	1,703
Four-seater, torpedo model, complete	14	1,124
Two-seater, complete	10	894
Four cylinders, victoria two-seater, hoods, screen, lamps, etc.	12-14	1,168
Four cylinders, five-seater torpedo phaeton, with hood, screen, lamps, etc.	16-20	1,411
Two-seater torpedo body, two cylinders, cape cart hood, wind screen, engine 85 by 85 mm. (3.3 by 3.3 inches), chain drive, two speeds, Dunlop tires	8	803
Four cylinders, four-seater, complete with Dunlop tires	12	1,387
Four cylinders, two-seater, car complete	20	730
Two cylinders, safety three-wheeler, two-seated torpedo	10-14	584
Four cylinders, chassis with tires.	10 13-16	706 1,022
Two-cylinder victoria seating three abreast, engine 102 by 115 mm. (4 by 4.5 inches), cylinders cast en bloc, Dunlop tires, with hood, screen, lamps, etc.	13	1,071
Four cylinders, torpedo two-seater.	12	1,095
Same, four-seater	12	1,183
Two cylinders, two-seated victoria, V-type engine, 85 by 88 mm. (3.3 by 3.4 inches), three speeds, worm drive, complete car	7-8	633
Four cylinders, four-seated double phaeton torpedo, with hood, screen, etc., spare tire and wheel.	11	1,509

Oldfield Bill Again Menaces Inventors

By Gilbert H. Montague

The revised Oldfield bill, House of Representatives 15,989, which was introduced on April 24, 1914, and the hearings on which are now in progress before the House Committee on Patents, of which Mr. Oldfield is chairman, follows closely on the original Oldfield Bill of 2 years ago, in that it virtually abolishes license restrictions by providing that no action for infringement may be brought for their violation, and cuts down, from 17 to 3 years, the patentee's absolute control over his patent, by providing that if after 3 years the patented invention is not put into use, the patentee may be compelled to grant a license to anyone applying therefor.

This bill proposes to deprive the patent owner of the right to sue pirating dealers and manufacturers as contributory infringers and to relegate the patent owner to separate actions for breach of contract against an army of small users whom these pirates instigate to break their agreements. This proposal leaves the patent owner virtually without remedy. Even if a thousand such suits were successfully prosecuted the damages would be small in each, uncollectible in most and less than the expense of litigation in all. Meanwhile, the patent owner would be practically helpless before the instigator.

The opponents of this bill declare that no aid which the existing law gives to the merchandising of patented articles can be called unfair. It has been shown repeatedly that the difficulties of merchandising are enormously increased in the instance of novelties. All patented articles are novelties at first and most of them continue to be novelties to most of the public until the 17-year patent period has expired. Considering the natural handicap thus imposed on the selling of patented articles, and the further fact that the patent owner must reap the benefit before the expiration of the 17-year period no aid which the existing law lends can be called unfair.

By the same token license restrictions agreed to by owners when they obtain patented articles, solely upon the condition that they use them only with supplies that are specially prepared for them, is to be countenanced. Mr. H. Ward Leonard, of the Ward Leonard Company, Bronxville, N. Y., maker of electrical apparatus for automobiles, says in this connection: "It certainly is a fact that in some instances a man's market for a good article would be completely destroyed if he could not insure himself in seeing that it was properly used after it left his hands."

The notion that such license restrictions might give patent owners a practical monopoly of the market for unpatentable products used with a patented device, is disposed of by the fact that such a practical monopoly, far from offending the public policy actually promotes the general welfare because the patent owners can attain it only by cheapening the cost of manufacture of the patented article and can continue only so long as their invention is not superseded by subsequent inventions, still further cheapening the cost of manufacture.

Some amendments in the patent law are certainly needed. Few will disagree that some legislation other than that proposed in the Oldfield bill is required. Changes should be made in the equipment and organization of the Patent Office to increase its efficiency and to secure for the public and inventors, whom it serves, the best possible service. By changes of this sort, rather than by the radical innovations proposed in the Oldfield bill, will the patent system of the United States be improved.

Makers Save by Using S. A. E. Standards

Opinions from Representative Makers Indicate That Economy of Time in Design and Manufacture and in Cost of Material Are Salient Features

ECONOMY in every branch of the industry is the direct result of the use of the standards that have been set by the S. A. E., is the consensus of opinion according to the various representative manufacturers. First of all there has been a cash saving in the purchase of raw material because the steel mills make comparatively few steels according to the S. A. E. specifications where heretofore the demands of each individual manufacturer had to be satisfied. A saving in time of delivery has also been effected here, as it is quicker to get a standard article than a special one. Less misunderstanding, fewer mistakes and economy of time in ordering the material have also resulted.

In the drafting room, a great deal of time has also been saved, as now in designing many small parts the draftsman merely refers to the S. A. E. handbook. Reduction in the stock of repair parts is another result as the same size of yoke ends are often used on several models.

Economy in time and trouble to the owner has also been effected. For instance, a spark plug can be purchased at any supply store. But if it were not for the standardization of this part, it probably would be necessary to send to the factory for it.

Expressions of opinion as to the value of the work the S. A. E. Standards Committee has done are given below.

Wheel Rims Most Important

"We have followed very closely the work of the Standards committee of the Society of Automobile Engineers and this work has been of great value to our company. If there is any one thing that is more valuable than the others, it is, perhaps, the standardization of truck wheel rims. The writer would consider this to be of great value to the wheel builder, tire maker, manufacturer of trucks, as well as the user. It is not necessary for the wheel builder to carry special stock for each different order of wheels; it is not necessary for the truck manufacturer to carry special wheels for different makes of tires and the customer can very easily purchase any type of tire that he might fancy and be assured that it would properly fit the wheels on his truck.

"The standardization of carbureter fittings, magneto bases, brake clevises, etc., are of very great value to the manufacturer as well, and we feel that the work of the Standardization committee has been of great value and should be carried out farther."—C. B. Rose, Chief Engineer, Velie Motor Vehicle Co.

Advantage Is Unquestioned

"The advantage of the automobile industry of the standardization of parts, as worked out by the S. A. E., can hardly be questioned. It is equivalent to having a large force of the best engineers in the country working out details in your factory. This advantage begins first with the designing engineer and saves him considerable annoyance and time. In the drafting room it saves a number of special drawings and the time required in working out these details. As making parts in large quantities cheapens production, the purchasing department finds that it is much easier and cheaper to buy parts which have been standardized by the Society of Automobile Engineers.

"Also time of delivery is very materially shortened, which often prevents costly and wasteful delays. In the machine shop standard tools can be used for making these parts. This materially reduces the tool room force. There is a saving on the assembling and erecting floors, as standardization has a tendency to reduce a large number of small parts of different types to a fewer number of the same type. The stock keeping and cost departments can also be run more cheaply."—W. G. Wall, Chief Engineer, National Motor Vehicle Co.

Packard Uses Standards

"In designing new parts, we are working to the S. A. E. standards wherever possible. For instance, we have changed all our bolt heads, nuts, lock washers and what you might call standard parts to the S. A. E. standard, with the exception of threads. The Packard company, realizing the necessity for a fine thread on automobile work, standardized a set of fine threads at a very early date before the A. L. A. M. took the matter up. This means that our service departments all over the country are stocked up with our standard threaded parts and we could not make a change at this point without making it necessary to carry in stock an entirely duplicate set of parts.

"We have, however, adopted S. A. E. standards in a great many places where it would not affect our interchangeability list. Among other things, we have adopted the S. A. E. carbureter fittings.

"While we will not benefit from S. A. E. standards as much as people that buy a lot of their material finished, we know that such standards are a move in the right direction and we will gradually work into these standards wherever it does not affect our interchangeability to too great an extent.

"We know that it does simplify work, as draftsmen are always prone to invent something unless they are absolutely held down to a standard.

"We know it has saved us something, but as we had our parts pretty well standardized before this move, we have not saved as much as other companies probably have. We know of no way to get at even an approximate figure of just how much we have saved.

"We certainly favor standardization along sound lines to a degree that will not hamper the individuality of the engineer. There is no use in discussing this point, however, as I believe that practically the entire Society is agreed on this point."—J. G. Vincent, Chief Engineer, Packard Motor Car Co.

Room for More Work

"S. A. E. standards have been of most assistance to us in widening the market for readily available material and parts. The fact that certain materials are carried in stock by supply houses and by more than one supply house elimnates the uncertainty of delivery as well as reducing the cost. I find supply houses willing to carry in stock standard parts when they would not before carry similar parts or material at all, before standardization.

"I regret, however, that there are not more standards directly benefiting the electric vehicle and hope the trend of society in this respect will result in work of value to electric vehicle manufacturers. This is not to say that there are not already some standards which are of great value to both the gas and electric types of vehicles. I believe, however, that there is room for a great deal more standardization and I think that more work along this line is going to be speedily accomplished."—H. H. KENNEDY, Chief Engineer, The Waverley Co.

Saves Trouble—Pierce-Arrow

"The true value of the work of the Standards committee of the S. A. E. combined with the work of the technical branch of the A. L. A. M. can only be fully appreciated by those automobile manufacturers who were in the business prior to the time of such standards. The Pierce-Arrow Motor Car Co. had to design from the very first special screws, nuts, bolts, etc. With a finer thread than the U. S. standard, difficulty was experienced in purchasing special taps and dies, gauges, etc. All these had to be made by us. The tapping hole for spark plug was always a source of misunderstanding and annoyance. The Pierce-Arrow Co. adopted the metric as that was about the only standard at that time. Other manufacturers used a gas thread and there were quite a number of other sizes in vogue. It was difficult to get a correct metric thread from the American spark plug manufacturers.

"In regard to specifications for materials, the Pierce company had to formulate its own steel, cast iron, bronze and aluminum specifications. Frequently these conflicted with the steel manufacturers and foundries, endless correspondence resulted, frequently a compromise had to be accepted, as few of the large producers cared to cater to individual requirements unless the tonnage involved was very great. Where a steel mill consented to work to special specifications, they charged excessively, and frequently we were delayed in manufacturing by the material not being delivered on time. This led to purchasing some of the alloy steels abroad and we frequently could get more prompt shipments from the foreign houses. Most of the drop forge companies had never heard of heat treatment as applied to forgings.

"Now the S. A. E. standards are recognized. We scarcely ever need go outside the S. A. E. material specifications to find the grade of material we desire to use, and we have the assurance that these can be supplied promptly by a dozen different houses.

The S. A. E. standard threads for nuts, bolts, etc., are a great boon, especially in case of any equipment purchased from outside sources. Spark plugs can be had anywhere that will be a fairly good fit in the cylinders. The S. A. E. limits on ball and roller bearings are already tending towards a better product at no additional cost."—D. FERGUSSON, Mechanical Engineer, The Pierce-Arrow Motor Car Co.

Timken Uses Three Standards

"The S. A. E. Standards which affect our work peculiarly are only three at the present time, namely, the finish of brake lever eyes, the finish of pinion shaft for the universal joint flange and the dimension of splines for shaft fits.

"Regarding the latter, this company had already adopted its own standard before the S. A. E. adopted theirs. We shall, however, on new work adopt the S. A. E. standard for this class of work in every case.

"On the matter of pinion shaft finishes, the adoption of the S. A. E. has been of very considerable benefit to us. One of the most annoying things in connection with axle construction is the different finishes on pinion shafts which individual motor car manufacturers have in the past insisted upon. Within the last year or more our policy has been to urge, and insist upon—as far as possible—the use of the S. A. E. Standard taper sizes, and we are pleased to say we have gotten very nearly all of our customers over to this construction.

"In the matter of brake lever eye sizes there has in the past years been a great deal of confusion, but it is growing constantly less because of the adoption of S. A. E. standards by motor car manufacturers. We throw all of our influence in that direction and the adoption by the car builder of S. A. E. Standards has enabled us to reduce the number of parts to manufacture and to carry in stock, in the way of brake levers particularly. We are heartily in accord with this work of the Society, and while it is a difficult matter to figure out in dollars and cents the actual saving to us, it is very easy to notice the saving in confusion and complication of parts going through the plant, and we sincerely hope that this standardizing activity of the Society will continue.

"It really has been of unquestionably very great advantage to us and we would welcome a reasonable extension of standards to other parts of our axles, as experience and occasion will make possible."—H. W. ALDEN, Chief Engineer, The Timken-Detroit Axle Co., Detroit, Mich.

"The work of the Standards committee of the Society of Automobile Engineers to the Cunningham factory has certainly leveled off a lot of knotty points, both from the standpoint of design and manufacturing.

"We have followed the policy of adopting S. A. E. standards at every point where we have been able to work them in. Manufacturing conditions in some instances have delayed the adoption of some of these standards, but we work them in as fast as possible.

"One of the great advantages from the manufacturing standpoint is that we are able to write our specifications, calling for certain material, and simply note that it is to be of S. A. E. standard. This is then indicated on the orders of our purchasing department, and when the goods arrive they are invariably found to be what we want. Without the S. A. E. standards many goods would necessitate considerable description, which might be misinterpreted by our purchasing department, and in turn by the concerns from whom we buy, with the result that many errors would creep in, as they actually did in days before the S. A. E. standards were made, and no end of trouble was the result.

"We most heartily recommend the work of the Standards committee, and certainly trust that the good work will go on for there are many other features about automobiles which could be taken up by the committee without in the least curtailing originality of design."—V. E. LACY, James Cunningham, Son & Co., Rochester, N. Y.

Facilitates Work in Drafting Room

"The standards recommended by the committee have been of assistance because of the fact that manufacturers of carbureters, spark plugs and small fittings are making their products to conform to the standard. Also the metal standards, having to do with composition and heat treatments of steel as well as bearing metals greatly facilitate work in the drafting room and purchasing department. We are also much interested in the standardization of motor mounting dimensions and transmission flanges and our newer models conform to the standards recommended as closely as possible.

"The work of the society has been of great value to the manufacturer who has taken advantage of it and should receive the hearty support of all people engaged in this line of work."—PITTSBURGH MODEL ENGINE Co., Pittsburgh, Pa.

Benefit to Industry—Lozier

"The value of standardizing certain parts entering into the construction of motor cars, both from the stand-

(*Continued on page 77*)

Proposes Standardization of Car Sizes

The Automobile Engineers' Forum

Such a Plan Would Render Possible Thorough Standardization of All Parts, Would Reduce Manufacturing Cost and Selling Price and Facilitate Repairs and Replacement

DETROIT, MICH.—Editor THE AUTOMOBILE:—President Leland's address before the Society of Automobile Engineers is to be admired for its sentiments, but I beg to take exception to his quotation from Bailey, in which he says:

"He most lives who thinks most,
Feels the noblest, acts the best."

This statement, as with everything else in the world, depends on conditions. For instance, there are many inventors or so-called inventors who have thought a lifetime on a subject and never accomplished anything, for the simple reason that they had not been thinking along the proper lines.

The Public Neglected?

Here is, to my mind, another practical illustration:

The S. A. E. has begun to create standards that to all intents and purposes assist the manufacturers, but the public and user, the main issue, have been entirely eliminated. Their thoughts have been all on the saving in manufacture and in doing so have confined their thoughts to the standardizing of parts instead of cars, with the result that there have been two thoughts most of the time when one would have produced greater benefits.

Standardize Car Sizes

You will notice I said standardizing cars instead of parts. At present there are about ten grades of cars, according to price. To be plain, we will say there are $500, $750, $1,000, $1,200, $1,500, $1,800, $2,000, $2,500, $3,000, $3,500, $4,000 cars. There are more, of course, but this is by way of illustration, and these cars all have different weights, different models, to the number probably of 100, these then have parts to the number of 4,000, and the S. A. E. has begun to standardize these parts, which to me is like having 4,000 beans and ten peas mixed up and starting to pick out the beans. What I would suggest is to pick out the ten peas from the beans, or in other words to set a standard of weight for cars. A 500-pound car, a 750-pound car, 1,000-pound car, a 1,500-pound car, an 1,800-pound car, a 2,400-pound car or chassis—from these six sizes a man can get any kind of a car he wants; each of these shall be standard length of wheelbase for each weight; each will have a standard engine support, standard cross members, standard radiator setting or support.

Standard Wheel Sizes

Having decided the weight of chassis in designing we know we could have standard size wheels for this chassis; therefore we would have standard size tires, for example: a 500-pound car would have 28 by 2 1-2; a 750-pound car would have 28 by 3; a 1,000-pound, 30 by 3; a 1,500-pound, 32 by 3½; 2,000-pound, 34 by 4; 2,500-pound, 36 by 4½. We would then have six standard tire sizes instead of forty-six according to a catalog I have at hand, and, mind you, the tire companies are in a position to give you much better service than you are now getting; competition will be more uniform and manufacturers can offer no excuses for putting on any but the proper size tire. While we are on the tire question let us take up the rim question. A great source of unnecessary weight and expense to both maker and user alike is the demountable rim, which should be abandoned as well as the old solid clincher. The quick detachable is a good, simple and efficient arrangement and cannot be improved upon, provided you have a good mechanically operated air pump.

Ordering Parts by Car Size

Having standard wheels we may now have standard hubs and bearings as well as standard spindles and axles so that it would be only necessary to go to a first-class supply house and ask for a front bearing for a 1,500-pound car or a front left hand steering knuckle for a 1,000-pound car. We could have standard springs, standard shackles, standard front axles, of which about six sizes would take care of every car made; the design could differ for the different ideas of different makers but their dimensions would have to be standard. We could have properly designed brake runners that would fit one and all standard brakes, shoes, etc.; the same principle applies to all; why not standardize them?

Standardize Fuel Feed

We have now three methods of feeding gasoline to carbureter, gravity, vacuum and pressure, and three or four places to put them. Why not standardize these? Make one size for each of the different size cars, one place to put it and have pressure feed. This is the best when properly applied. We can now put our carbureter as near the cylinders as necessary and instead of a standard flange for the carbureter we might standardize the intake, whether it be cast in the cylinder block or not. This would give standard gas pipe connections and fittings and standard throttle connections on steering gear and accelerator. We could also standardize a place for the steering column and have manufacturers mark their product to fit the car in place of making the car to fit their products.

Dropping Fads and Fancies

Automobile designers in the past have had too many fads and fancies; they think they must change something or they are not doing anything. They want to do now what foreign makers have done to a certain extent—to find out what really and positively is best, like the ideal car which was discussed at the meeting of the S. A. E. On some subjects there is a chance for endless argument; these must be taken up in a scientific manner and if properly thought out will be of inestimable value.

I have here only touched on a subject of gigantic proportions. The details I have mentioned form the foundation of my reasoning and it is only through discussion and criticism, and I might add, tests, that the Ideal car shall ever become a reality. In the same manner we might treat the horsepower of chassis; for a 500-pound chassis we could use a 10-horsepower engine; for 750 pounds, a 15-horsepower; 1,000, a 20-horsepower; 1,500 pounds, a 24-horsepower; 2,000 pounds, a 30-horsepower; 2,500, a 40-horsepower. This would equalize racing, making it easier to judge the merits of cars and place cars in the proper class. It is only through an organization such as the S. A. E. that this work can be accomplished, after which, I believe, the industry will be on a better manufacturing and commercial basis.—WILLIS A. SWAN.

Thinks Brakes on Cars and Trucks Are Often Inefficient

WILKES-BARRE, PA.—Editor THE AUTOMOBILE:—It pleases us to note that you are giving attention to the question of brakes on automobiles as mentioned in your editorial June 18 issue of THE AUTOMOBILE.

We have been laying a great deal of emphasis on the question of reliable brakes in our advertising the last 2 years, and, in this portion of axle equipment, have always considered safety as the first and foremost consideration. Our brake equipment for motor trucks has been developed here in the mountains, and we believe that we have the most efficient brake as the result of this, of any equipment on the market.

Some of our customers have been inclined to think that we demand more of the brake than we should, but we believe that is not true as it will only be a question of time when the city fathers will exercise and take steps towards an examination and testing of brake equipment on automobiles and trucks especially in the congested districts. It is surprising to see what a large number of equipments are in operation in various parts and dangerous parts of the cities with brake equipments that will hardly stop the truck in its length without load, to say nothing of what would happen if the truck were called upon to stop suddenly with its full load. All of our brake equipment is designed to safely handle a truck with its full rated load, and lock the wheels without difficulty.

We believe that you are doing a lot of good for the motor truck industry in particular if you continue to lay emphasis on this subject of Safety First in brake equipment.—THE SHELDON AXLE CO.

Makers Save by Using S. A. E. Standards

(*Continued from page 75*)

point of production and economical purchase of material, has been proven by the extensive adoption among automobile manufacturers of the various standards evolved by the Society of Automobile Engineers.

"The Lozier Motor Co. has been specifying S. A. E. standards for some time, covering such parts as lock washers, yoke ends, spark plug threads, shaft tapers, copper tube fittings, bolts, nuts, screws, studs, etc., and contemplates the adoption of further S. A. E. standards as soon as they may be advantageously worked in.

"The use of such standards not only enables the manufacturer to obtain prompt deliveries on a stock article, thus eliminating the long delays consequent on a special parts proposition, but also tends towards rapidity and economy in production. Also the matter of standardization from a service standpoint is a most important item.

"From our own experience we believe the work of the Standards committee of the Society of Automobile Engineers has resulted in much good to the industry generally, and their continued efforts along these lines should prove beneficial to all concerned."—J. G. PERRIN, Chief Engineer, Lozier Motor Co., Detroit, Mich.

S. A. E. Standards—Best Practice

"The value of the work of the Standards committee of the Society of Automobile Engineers is imperative to every manufacturer of automobiles. The greatest value in the work of the Society of Automobile Engineers' Standards committee is the fact that they have created standards for parts, which represent the best accepted practice for the particular kind of work which these parts have to perform, the design of which is accepted by all of the engineers of the automobile industry.

"The creating of the S. A. E. standard of bolts, nuts and lock washers, yoke ends and I-rod ends has placed every manufacturer of automobiles in a position to purchase these articles from practically any manufacturer of screw machine parts, and a great many of the manufacturers carry these parts in stock for immediate delivery at a very small increase in price over the less desirable article which they replace.

"The recommendations made by this committee have caused the steel manufacturers to produce and carry in stock alloy steels in special sizes and shapes to meet the requirements of work these particular parts have to perform in the construction of automobiles.

"The above, to my mind, represents the greatest advancement in automobile manufacturing and has been of great benefit to the engineers of the various factories in their ability to obtain material which is best suited for their requirements."—R. S. FEND, Chief Engineer, Woods Motor Vehicle Co., Chicago, Ill.

Standards of Value—Cadillac

"We are heartily in favor of standardizing the various parts that go to make up an automobile, and we know that standards thus far established have been helpful.

"Perhaps the reason that we have not used more of the S. A. E. standards up to date is because we were manufacturing automobiles many years before the S. A. E. was active in formulating standards, and our management was not entirely satisfied with the then existing standards, or rather lack of standards. Therefore we established some systems known as Cadillac standards, that seemed to meet our requirements much better than anything available at that time. And because of establishing certain standards which have been incorporated and are interchangeable in our various machines, we have been quite reluctant to adopt some of the S. A. E. standards until we might be designing something entirely different from our previous construction, so that we could afford to ignore our past standards, in which case we give careful consideration to the S. A. E. standards and adopt them as far as possible.

"We believe that eventually the S. A. E. standards will be of great value to the automobile industry."—E. E. SWEET, Consulting Engineer, Cadillac Motor Car Co., Detroit, Mich.

Interchangeability of Parts Increased

"We use S. A. E. standards on all yoke and rod assemblies and on all bolts and nuts with the exception of such bolts as are used in aluminum. We find the standards of the S. A. E. satisfactory in every respect and will continue to enlarge on our use of them.

"We think the Standards committee is entitled to a great deal of credit for the work they have done and we trust that they will pursue the subject in the future with the same amount of vigor that has been displayed in the past as we feel sure that nothing but good will come of it."—W. J. PECK, Chief Engineer, Bartholomew Co.

Center Steer on Buffalo Electrics

Motor Acts as Brake in New Five-Seater—Cantilever Rear Spring Used

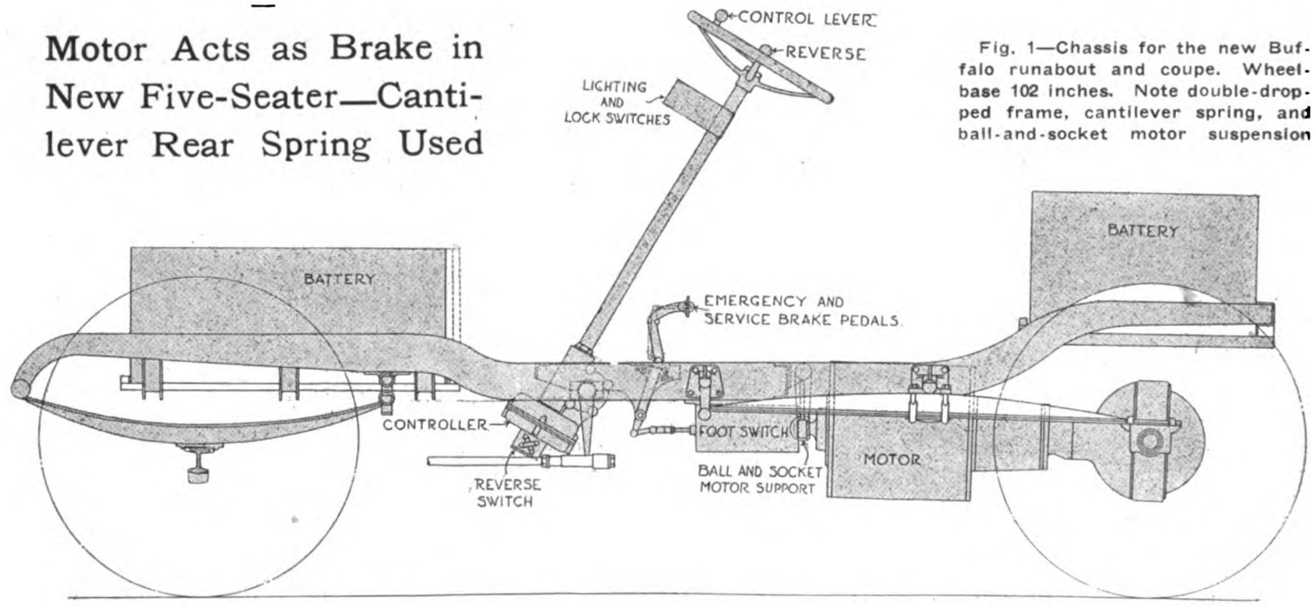

Fig. 1—Chassis for the new Buffalo runabout and coupe. Wheelbase 102 inches. Note double-dropped frame, cantilever spring, and ball-and-socket motor suspension

THE Buffalo Electric Vehicle Co. comes forward this year with a model that not only differs in many important features from the Buffalo electrics of previous years but one which possesses characteristics that distinguish it from the general field,

Most pronounced of these radical changes is the introduction of a central contiol system, that is, the central position of the steering wheel and brake pedals, the driver occupying a seat strictly in the middle of the floor. The vehicle seats five, two swivel seats being in front with sufficient space between them to allow an unobstructed view for the driver, while the remaining two seats are located at each side and slightly to the rear of the driver, Fig. 2.

Other changes over last year's models are the use of cantilever springs at the rear, a double-dropped frame, and a ball and socket front end support for the motor. The body has also been entirely redesigned to streamline principles and as shown in Figs. 6 and 7 the result is highly satisfactory. The method of regulating the motor by means of a lever on the steering wheel in addition to a foot controller operated in conjunction with the service brake pedal is retained.

Motor Acts as Brake

The motor used is again of Diehl manufacture but it is a special design so wound that the driving speed of the car is largely automatic irrespective of the grade over which the vehicle is traveling. This feature is obtained by using the motor as a brake on down grades, the braking effort being controlled automatically by the speed at which the car attempts to run. The current generated at this time by the motor in its capacity of a generator passes as charge into the battery. In this way a considerable extension of mileage per battery charge is obtained. The winding is shunt and the control is arranged so that the armature is never broken while changing speeds, the variation being effected only through resistances inserted in the fields.

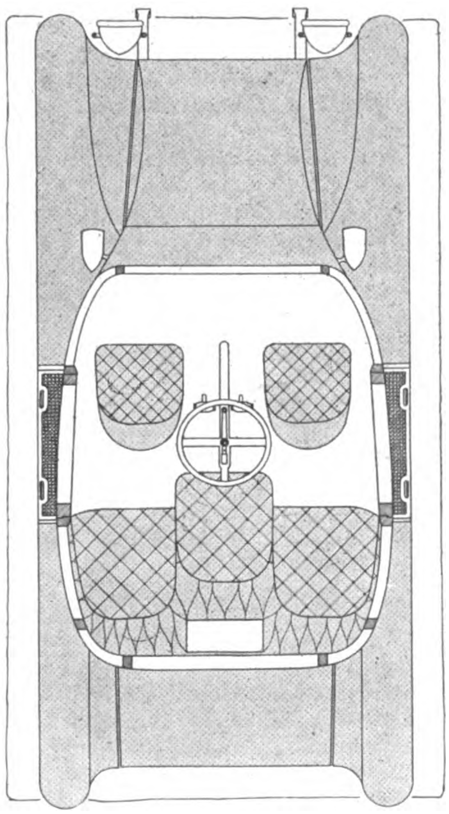

Fig. 2—Plan of the latest Buffalo electric, showing streamline body and central position of driver's seat

The controller is of the circular type and is remarkably compact. It occupies a position at the base of the steering column and operates by a radial brush arm actuated directly through the steering column by a short lever, Fig. 4, on the handwheel. Immediately beneath it and attached to the base is a reversing switch of the sliding contact type. This switch is operated by a knob in the center of the steering wheel. By means of a key at the top of the reverse switch rod sliding into a keyway in the boss of the control lever it is impossible to use the reversing switch except when the control lever is in the neutral position. The small size of the reversing switch is possible by the method of reversing the motor on the field instead of on the armature. The current passing around the field of a shunt wound motor being small the copper parts of the switch can of course be made correspondingly light.

Pedal Control Continued

In addition to the hand controlling device the Buffalo Co. still make use of the pedal operated switch which is capable of controlling the car within speeds of 9 to 20 miles per hour. The foot switch is located under the floor, Fig. 1, and is connected by linkage to the emergency brake pedal. It is a three-point regulating switch affording all necessary resistance for starting, stopping, and speeds up to 9 miles per hour. It will thus be seen that the car can be started by the pedal without the hands being used for other purposes than steering.

A distinct departure from ordinary practice in electric design is the support of the motor on a single point at the front end in place of the double-trunnion suspension used last year. The new suspension consists of a bronze ball in a steel socket hung from a cross member. No universals are used and therefore the torque is taken directly by the drive shaft casing which connects the motor solidly with the rear axle housing. The axle used is of Timken manufacture with the new curved bevel differential by which it is claimed extreme quietness of running is obtained. There is no other reduction that the differential, which has a ratio of 5.13 to 1 with the motor shaft. Both brakes act on 14 by 2.25-inch drums on the rear axle.

Several interesting details of body design are noticeable in the new coupé, besides the seating arrangement. All angles have been removed from the outline which is streamline as much as possible. The hood over the battery is hinged where it meets the curved cowl, but the joint is practically invisible by the employment of specially designed concealed hinges, Fig. 5. By the construction of this hinge a close butt joint is always made when the hood is lowered, but to make it absolutely impossible for moisture to work into the battery compartment a curved gutter shown in the illustration is provided to carry off water to the side and through underneath. The battery space this year is large enough to accommodate any make of standard battery, including the Edison. There is no particular battery specified. When the Edison is used 70 A4 cells are carried, being disposed 40 in front and 30 behind. In the plan, Fig. 2, it will be seen how the rear battery space is

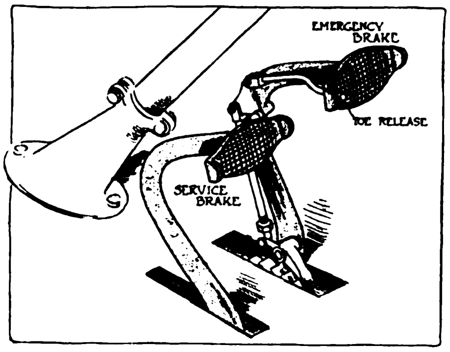

Fig. 3—Brake pedals at the foot of the steering column. The service brake also operates a control switch

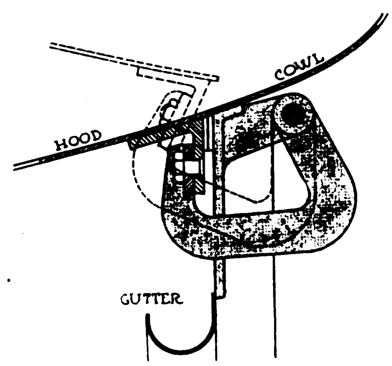

Fig. 5—Special concealed hinge for hood over battery. A gutter is provided to collect any moisture passing through the joint

much lessened externally by placing several of the cells in the center tray between the rear seats. When lead cells are installed the battery consists of 42 15-plate cells with a capacity of 140 hours.

A double-rain vision shield is fitted and sashless windows in felt runways are used. The door window is operated by a mechanical lifter. The door is 26 inches wide and on opening it a step light is automatically turned on. The double-dropped frame lowers the floor about 3 inches and makes for easier entrance.

In the coupé the front seats are of the swivel type but in the runabout model which also seats five,

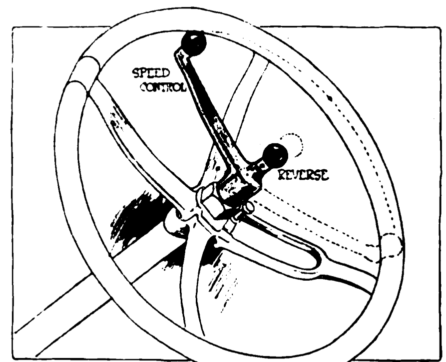

Fig. 4—Showing simplicity of control mechanism on steering wheel. A swing wheel is used for ease of entrance

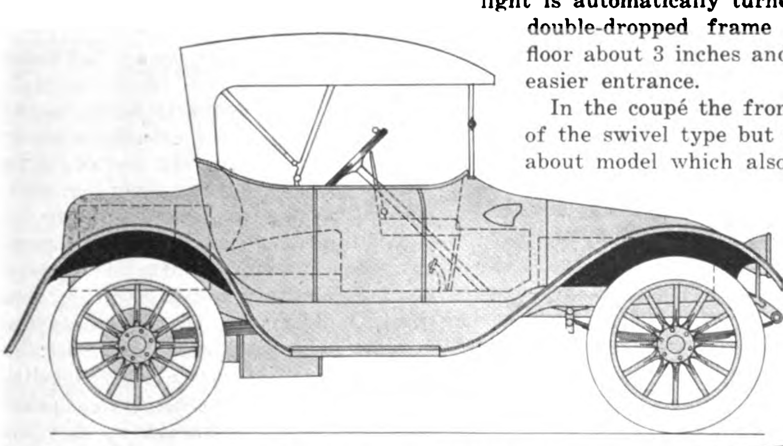
hinged seats which fold under the cowl are fitted. In both models the lighting switch is mounted conveniently on the steering column as is also a lock switch which cuts off the entire current and prevents the car from being started. An instrument board containing an ammeter, voltmeter and clock is located in the center of the dash. The space at either side is handy for luggage. Between the rear seats of the coupé there is further accommodation for packages, so that the interior can be left unencumbered. For the comfort of the driver the pedals are made adjustable through a range of several inches, the change being easily effected by a telescopic link just under the pedal. The bodywork is designed and made at the Buffalo Electric factory, including the hoods which are in hammered aluminum fitting flush without beading against the cowl.

In actual road tests made with the new vehicle the economical result of 63 watts per ton-mile has been obtained.

Preparations are in progress for increasing the factory facilities. At present only two models are on the market though the coupé can be fitted with a folding landaulet back if desired. The price of the coupé is $3,200. The price of the runabout is not yet fixed but it will probably be in the neighborhood of $2,600.



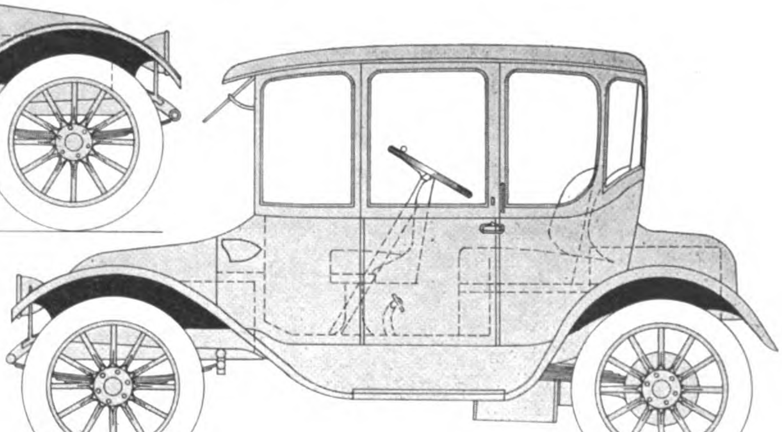


Fig. 6—The new Buffalo electric runabout is built on the same chassis as the coupé. Note low, speedy appearance obtained by smooth exterior lines and the adoption of the double-dropped frame

Fig. 7—Side view of the latest Buffalo coupé, showing arrangement of seats and the use of the interior space behind the central driving seat to accommodate part of the battery

Economy Is the Truck Tire Issue

Light Loads, Low Speeds and Tires of Good Materials and Solid Construction Mean Satisfaction for Owner and Maker

From a Paper Read at the Summer Session of the Society of Automobile Engineers at Cape May by James E. Hale, Experimental Engineer, Goodyear Tire & Rubber Co.

TAKEN in a broad sense undoubtedly economy of truck operation is the real issue. It follows, therefore, that if an economical tire could be evolved an ideal solution would be at hand.

Solid tires in service under certain operating conditions give certain results in the performance of their functions. These results are dependent on the tires themselves and on the conditions under which the tires are used; consequently we may propose an equation which indicates a balancing condition as follows:

The results of service performance, which may be termed "commercial properties"	$=f$	Operating conditions	&	Tire details or physical properties of the tires	&	Selling cost

Expanding the terms in parenthesis by itemizing the features pertinent to this discussion we have:

Cost per tire-mile Durability (Total Mileage) Resiliency (Power Consumption) Cushioning-effect Reliability Service cost Tractive grip	$=f$	Loading Speed Spring-suspension Road surfaces Topography Weather Driver	&	Structure Diameter Width Shape cross-section Tread rubber Toughness Attrition-resistance Plasticity Scheme of attachment Weight	&	Selling cost

The commercial properties, representing as they do the results of service performance, are of particular interest as they are a measure of the satisfaction received. Cost per tire-mile, durability, tractive grip, service cost, and power consumption are all capable of being expressed by exact numerical values. Cushioning effect and reliability are indefinite but none the less important.

The operating conditions, loading, driver, and to some extent, choice of road surfaces are under the control of the truck owner. The spring suspension is wholly and the loading to some extent under the control of the truck designer. Topography, weather, and in part the road surfaces must be accepted as they are. Of the operating conditions, loading and speeding alone

Haleisms on Truck Tires

1—**The value of the finished tire is largely in the materials which enter into its fabrication.**

2—**A tire which runs its mileage guarantee without developing any distressing symptoms is satisfactory.**

3—**A tire that exceeds its mileage guarantee will get the business in the future.**

4—**A tire that fails to give the mileage guaranteed gets a black eye.**

5—**Service helps to sell tires.**

6—**Extremes of heat or cold have a detrimental effect on the rubber and increase cost per ton mile.**

7—**The lighter the load and the slower the speed the lower the cost per ton mile.**

8—**Resiliency will presently occupy a decidedly more prominent position in the list than it has in the past.**

9—**Truck operators should recognize the possibility of greater economy from the use of efficient tires, just as does the electric truck owner.**

10—**The resiliency of the tire is largely dependent on the compounding of the tread rubber.**

may be expressed in numerical values.

The items under tire details pertain to the physical properties of the tires themselves and are self-explanatory.

In this discussion it may be noticed that cost or money value is mentioned only in connection with the commercial properties of the tires. Of course the item of cost is present on the other side of the equation in the various subdivisions of the tire details.

Value Is in Materials

Without being specific as to the precise relation between cost and tire details, let it suffice to say that the value of the finished product is largely in the materials which enter into its fabrication.

This equation is explained as representing a balancing condition. Of course this is true enough if we have been careful to include all the component subdivisions relative to the main parentheses of the equation. It will shortly be pointed out that practically all the terms on both sides are variables between rather wide limits and that broadly speaking the whole situation centers about what we do not know and what we want to know about the effect produced on the "commercial properties" by changes or alterations of the various "tire details" or "operating conditions."

To take an example, we might accumulate data upon a certain tire of average physical properties and which had been in service under average "operating conditions" (Chicago for instance) and for commercial properties we would find the cost per tire-mile to be ¼c. The mileage given, 10,000, the power consumption, 9/10 horsepower-hour per ton-mile per tire, the tractive grip represented by an average coefficient of friction of .40, a service cost of 1¾ hours interruption of service in changing tires, and the cushioning in its effectiveness to reduce destructive vibration while not capable of definite expression in figures is nevertheless a very important and definite quantity.

Cost per Ton Mile Increased

Now, if we change any of the variables on the right-hand side of the equation this will naturally result in a change in one or more of the commercial properties. Assuming for instance that the speed (that is the average speed at which the truck is driven) be diminished, we will find the cost per tire-mile decreased, the durability increased, the resiliency altered, the cushioning effect increased, the reliability increased, the tractive grip probably increased and the service cost unaltered. On the other hand suppose we change one of the physical properties of the tire, say stiffen the compound. The cost per tire-mile would probably be reduced, the total mileage probably increased, the cushioning qualities decreased, the reliability unaltered, the tractive grip diminished, the service cost unaltered, and the power consumption decreased or increased according to road surfaces.

The Feature Tire

ALTHOUGH THE CIRCUMSTANCES ARE FAMILIAR TO EVERYBODY, LET US ENTER HERE AS A MATTER OF RECORD AND COMPARISON THE EXISTING SCHEME OF JUDGING THE SATISFACTION OBTAINED FROM THE SERVICE OF SOLID TIRES. IN A FEW CASES, NOTABLY AMONG THE LARGE OWNERS, COST OF TIRE-MILE RECEIVES CONSIDERABLE ATTENTION, BUT IN GENERAL IT MAY BE SAID THAT A TIRE WHICH RUNS ITS MILEAGE GUARANTEE WITHOUT DEVELOPING ANY DISTRESSING SYMPTOMS IS SATISFACTORY, A TIRE THAT EXCEEDS THE MILEAGE GUARANTEE GETS THE BUSINESS IN THE FUTURE, AND A TIRE THAT FAILS TO GIVE THE MILEAGE GETS A BLACK EYE. ALSO IT OFTEN HAPPENS THAT SERVICE HELPS TO SELL A TIRE.

The "commercial properties" should be discussed more or less in detail since they represent the satisfaction obtained from the use of the tire, and also the possibilities of choosing the best possible combination of component operative conditions and tire details to fulfill the requirements of the "economical tire." In what follows it should be borne in mind that economy of truck operation taken as a whole determines for our discussion the actual values of the commercial properties of the "economical tire."

Cut Tire-Mile Cost

Obviously it is desirable to have the cost per tire-mile as small as possible consistent with the complete qualifications for economical truck operation. This is one of the most important of the commercial properties in the matter of economy and it happens that it is dependent on practically all of the subdivisions of the operative conditions and physical properties of the tires. The better the road surfaces and more nearly level the country, the lower the cost per tire-mile. Likewise the tires will show up better under a careful driver than a careless one.

Factors in Wear

As for weather, extremes of heat and cold have a detrimental effect on the rubber, consequently increasing the cost per tire-mile. Spring suspension is mentioned as one of the operating conditions. This may seem a little farfetched, yet we know that the efficiency of the springs in performing their functions has a very decided effect on the life of a tire.

Considering now the load on the tire and the speed at which the truck is operated, *all will agree that the lighter the load and the slower the speed*, the lower the cost per tire-mile, but returning to our fundamental idea of economical operation of the truck there is undoubtedly one combination of load and speed (assuming tire equipment of specific "physical properties") which will give a maximum effect in the matter of truck operating economy, yet the cost per tire-mile will be greater than were the speed to be slower and the load less. Again by simply altering one of the tire details, say stiffening the compound, an entirely new set of relations will be established, with the result that the economical load and speed will differ from those of the preceding case. Change the structure, diameter, width or shape separately or collectively and our economical load and speed have to be sought anew and also a new cost per tire-mile.

Tire Durability

Strictly speaking durability is a property which is closely allied to that of cost per tire-mile and there is a strong temptation to believe that they are inversely proportional.

The principal exceptions to this are to be found in the details of the tires themselves. Thus it is perfectly possible to compound the tread rubber to give a very low cost per tire-mile and at the same time produce a tire which would give but small total mileage. The same idea could apply in the case of the structure of the tire under certain circumstances. Apparently the predominant attitude of the wideawake truck owners is decidedly favoring the choice of tires which run long mileages. The importance of uninterrupted operating schedules is undoubtedly largely responsible for this condition; moreover it is probably true that many owners would feel justified in sacrificing, if necessary, a slight saving in tire cost if it came to the point of choosing between the two properties.

Resiliency in Future

Resiliency will presently occupy a very decidedly more prominent position in the list than it has in the past. The requirements of electric vehicle practice have for some time demanded the most efficient tires possible; some manufacturers even make the other commercial properties secondary to this one. Surely gas truck operators should recognize the possibility of greater economy from the use of efficient tires just as does the electric truck operator.

AN EXAMPLE WILL EMPHASIZE THIS POINT. IT IS VERY EASY TO PICK OUT FROM AMONG THE BRANDS AND TYPES OF TIRES ON THE MARKET THOSE WHICH WILL ABSORB 25 TO 40 PER CENT. MORE ENERGY THAN THE MOST EFFICIENT; CONSEQUENTLY IF A 3-TON TRUCK CONSUMES SAY FROM $400 TO $500 WORTH OF GASOLINE A YEAR, A VERY CONSIDERABLE CASH SAVING COULD BE MADE BY USING MORE EFFICIENT TIRES. AS THE RUBBER IS "LIVELY" OR "DEAD" (BY VIRTUE OF THE NATURE OF THE COMPOUNDING) SO WILL IT BE EFFICIENT OR INEFFICIENT WHEN MEASURED FOR POWER CONSUMPTION. THE STIFFNESS OR PLASTICITY OF THE COMPOUND ALSO PLAYS AN IMPORTANT PART IN THE DETERMINATION OF EFFICIENT PERFORMANCE.

EFFICIENCY IS VERY DEPENDENT ON THE CHARACTER OF ROAD SURFACE OVER WHICH THE VEHICLE IS OPERATED, PARTICULARLY AS TO THE DISTINCTION BETWEEN ROUGH AND SMOOTH ROAD SURFACES. OTHER THINGS BEING EQUAL THE SOFT TREAD RUBBER WILL GIVE GREATER EFFICIENCY ON THE ROUGHER ROADS.

From the foregoing it will be seen that the resiliency of the tire is largely dependent on the compounding of the tread rubber. To what extent it is dependent on the other physical properties of the tire is somewhat uncertain, but surely not to any marked extent. The efficiency varies slightly with extremes of heat and cold; also with different loads and speeds.

Cushioning Effect

The invention and especially the perpetuation of the India rubber tire were possible because of the benefit derived from the cushioning properties of the rubber as a lessener of uncomfortable and destructive vibrations. How many times has it been remarked that automobiles are possible because of the pneumatic tire? It is not true that motor trucks would not be possible without rubber tires? Just think of a 3-ton truck equipped with steel-shod wheels rattling over the average pavement at 8 to 12 miles per hour—and the poor pavement!

Soft-Tread Tires

Of course the plasticity or stiffness of the tread rubber is by far the most important item affecting this commercial property and it goes without saying that a soft yielding compound will protect the mechanism of a vehicle better than a hard stiff one.

The remaining items of tire detail each influence the cushioning effect in minor ways. It is rather unfortunate that up to the present time the tire companies have found no way of making a tread rubber of exceptional cushioning qualities and at the same time of low cost per tire-mile. We find that the softer and more yielding the stock the better its quality must be to give reasonable service, and quality represents price. This fact is also particularly noticeable: Tires made of soft compounds are very much more liable to fail structurally under heavy loading. It might be interesting to remark that there is one critical load for each size tire and for each speed where the cushioning is most pronounced; that is, a lightly loaded tire will bounce and thereby exaggerate vibration; on the other hand a heavily laden tire will show less response in cushioning due to its already highly distorted condition. Tires are similar to springs in this respect.

Factor of Reliability

The reliability of a solid tire in performing its functions needs very little comment. It is listed as one of the commercial properties because it is a property which is of considerable importance to truck operation as a whole. In the case of truck tires this property is practically entirely dependent on the tire details themselves.

The remarks concerning reliability apply equally well as to service cost; in addition there is of course the question of attention on the part of the selling house.

Tire's Tractive Grip

The effectiveness of the traction of a tire is dependent on the coefficient of friction between the tread rubber and the road surface. Consequently compound, width, weather (wet or dry), loading and the character and condition of the road surface are the principal elements affecting traction.

On dry surfaces there is no advantage to be found from the use of a notched or broken tread over the use of a continuous tread, for in either case the grip of the tire is dependent on the simple phenomenon of friction between the rubber and road surface. Wet or greasy pavements are well known to be annoying and often dangerous. The coefficient here is exceedingly low, ranging from .11 to .15 or .20, whereas it would be from .50 to .60 on dry pavement. I believe that under certain conditions the coefficient of friction between the tire and the surface can be greater than 1.00. This seems conceivable in the instance of a soft yielding tread compound on a firm rough surface.

Why Tires Wear

So far nothing has been mentioned about the ways in which tires wear out or fail. This should be outlined briefly as several of the commercial properties are directly dependent on the wearing qualities of the tires. You will notice that the various items under each main subdivision are enumerated as forms of legitimate wear or as forms of abuse. The significance of this is suggestive rather than absolute, the idea being to convey the distinction which one would observe in the case of perfect service.

A—Abrasion of tread rubber, due to
- 1—Tractive effort — Legitimate wear
- 2—Natural wear of rolling friction
- 3—Skidding — Abuse
- 4—Spinning wheels by quick starts
- 5—Sliding with brakes set
- 6—Wheels out of alignment

B—Cutting, chipping, or spreading of read rubber, due to
- 1—Sharp stones, glass, etc. — Legitimate wear
- 2—Poor road surfaces in general
- 3—Car tracks — Abuse
- 4—Use of anti-skid devices

C—Disintegration or deterioration of tread rubber, due to
- 1—Sun and heat — Legitimate wear
- 2—Allowing tires to freeze
- 3—Oil on garage floor — Abuse
- 4—Heating by excessive speeding

D—Failure of the tire structurally, due to — Abuse
- 1—Overloading
- 2—Speeding
- 3—Shocks and impacts from reckless driving over uneven road surfaces

E—Premature failure or wear due to imperfections of manufacture.

The foregoing is an exposition of the relevant elements entering into the determination of the proper tire sizes. This method of elaborating on the situation is apt to leave the inference that the situation is so hopelessly complicated that there is nothing in particular to be done except make the best of it.

On the other hand, I realize that there are many who, although they will not dispute the truth of the facts presented, will be tempted to depreciate their significance, preferring to dispose of the matter by insisting that "tires are tires" and that it is up to the tire companies to produce the goods. Before us is a summary of the items by which the service performance of the tires are judged and an exposition of the factors on which these various items depend, and finally the possibilities to be taken advantage of in the way of attempting to regulate the tire problems toward more satisfactory ends.

You gentlemen know to what extent operating conditions can be controlled and regulated. As for tire details those having a knowledge of tire design and manufacture realize that with proper attention to compounding and fabrication methods a wide variety of constant results is possible. I wish to bring out one point very emphatically, however: While it is possible to alter tire details so that results shall vary through a wide range, it is also true that if these details be altered with the idea of highly perfecting one commercial property, this may be at the sacrifice of some other property or properties of nearly equal importance.

WHAT DOES THE MOTOR TRUCK INDUSTRY WANT AS QUALIFICATIONS FOR A SATISFACTORY MOTOR TRUCK TIRE?

In other words what is the relative importance of the commercial properties?

Are we getting all the cushioning effect desirable consistent with economy of truck operation?

Should not more stress be laid on the property of power consumption for the ultimate benefit of economic truck operation?

How much should we sacrifice in the cost per tire-mile property and the durability to balance the other properties for the good of economical truck operation?

Manifestly all are not of equal importance. For instance if the cushioning effect be highly developed with the idea of decreasing the truck repair expenses by lessening the destructive vibration, this much is certain, the tread rubber will necessarily be of a soft yielding compound in such an idea. But we will find the cost per tire-mile increased and the durability diminished very materially unless we diminish the load which the tires carry, which in turn will raise the ton-mile cost of truck operation. To a slight extent, with the introduction of additional cushioning effect, the resiliency and tractive grip may or may not be altered.

Uniform Cushioning

If the stiffness or plasticity of the tread rubber of the various brands and types of tires be compared, it will be found that there is a wide variation. In spite of this, well-known makes of trucks in any locality, equipped with competing tires which exhibit these marked differences, will be found running side by side.

Surely so important a property as that of cushioning effect should be more or less uniform under similar conditions. I often ask engineers, owners, and drivers whether they want a hard stiff tire which will give almost no cushioning to the truck, or a tire which will protect the truck even if the tire-mile cost is a little higher. Some have never given the idea any thought, some (users particularly) do not care anything about the tire so long as it wears, some are looking for information, and a few have such decided convictions in favor of proper cushioning effect that they will not use solid tires of any description and choose the more expensive pneumatic.

This illustration of the relations between cushioning effect and the plasticity of the tread rubber is typical of a multitude of combinations of properties and conditions which might be portrayed. It would be an endless and wearisome task to enumerate and discuss all these combinations.

At the present time the formalities of truck tire merchandizing are limited to a guaranty of perfection in workmanship and a certain maximum cost per tire-mile. Also, each tire company has its own special list of permissible loads which each size of tire may carry.

Without dwelling on the shortcomings of this happy-go-lucky method of dealing in tires, permit me to call to your attention that in the iron and steel world it is customary to buy and sell material which fulfills the requirements of certain chemical or physical specifications. The art has been perfected to such an extent that the measurement of the elemental subdivisions is now a matter of every-day routine in the up-to-date office, and moreover it is recognized that buying on specifications is the only sane policy—fair to both purchaser and seller. Standardization is not by any means limited to steel; Portland cement, paints, chemicals, electrical apparatus, boilers, etc., are all more or less thoroughly standardized.

The Tire Equation

In outlining the solid tire situation I have proposed an equation representing a balancing condition between the results which the tires give in service on one side, and the details of the tires themselves, the cost of marketing and the conditions under which they are used on the other. By developing this equation in detail I have attempted to emphasize:

1. *The complexity of the solid tire problem due to the innumerable variables into which the whole may be subdivided.*
2. *The importance of recognizing that economy of truck operation in its broadest sense should be the guiding motive behind any solid tire considerations.*
3. *The fact that the performance of solid tires in service has never been given the proper attention in the matter of criticism from the angle of economic truck operation as a whole.*
4. *The logic of recognizing the "commercial properties" and the desirability of discovering their relative importance.*
5. *The limitations encountered in bringing about ideal conditions due to practically positive inability to regulate or control the operating conditions which are included under road surfaces, topography, weather, and driver.*
6. *The facts that the solid tires are still capable of considerable development and that this development is essentially a process of evolution and elimination; also that there are certain practical limitations in the production of the tires themselves which permit the attainment of high degrees of perfection of certain commercial properties only at a sacrifice of others.*

Standard to Attain

In conclusion I simply venture a general summary. The ideal disposition of truck tire standardization would be to prescribe standards of commercial properties to be attained when the tires are in service under standard road surface conditions; the variables under this scheme would be the tire details. However, inasmuch as it would be impracticable, to say nothing of being cumbersome, to test each tire for the values of the commercial properties, to determine whether they come up to standards or not, it would develop that once we have arrived at and defined a satisfactory condition in the matter of service performance, the simplest proposition would be to take cognizance of the physical properties of the tires themselves and standardize them together with the loadings, speed, and spring suspension.

Recent Court Rulings—Woman Driver Loses

By George F. Kaiser

THE fact that a chauffeur made a statement after an accident between a car which he was driving and a horse and buggy, practically admitting that the accident occurred through his fault and saying that he had been discharged 2 days after the accident, could not be held to bind his employer, was decided by Massachusetts Court recently.

A chauffeur was driving along a road; he came to a horse and buggy; the horse became frightened, shied and dragged the buggy over a bush against a stump; the buggy upset and the woman who was driving was thrown out and injured. She sued for her injuries and her husband also sued the motorist for the loss of her services. The Court decided that the accident was not due to the negligent way in which the automobile was being driven and gave judgment for the motorist.—*Gillett vs. Shaw*, 104 *N. E.* (*Massachusetts*) 719.

Dealer Liable for Rented Car

Arkansas Court holds that a person letting an automobile and a chauffeur for hire is liable for the chauffeur's negligence when he causes injury to passengers, when the latter exercise no authority over the chauffeur, except to direct him where they wish to be driven.

A man rented an automobile for himself and his guests in Little Rock, Ark., by telephone. When the car arrived he and his guests entered and told the chauffeur where they wished to be driven. On the way the car ran into an express wagon and the man who had rented it was killed and one of the women passengers was injured. There was some doubt as to whether the accident was caused by the negligence of the express man or the negligence of the chauffeur, but it finally was decided that the chauffeur had been negligent. The dealer proved that the chauffeur was an experienced chauffeur; that he had been in his employ for several years and never had an accident but that he had always been careful and skillful and further that the car cost $3,500 and was in perfect condition at the time of the accident. The dealer won out in the lower Court, the Court holding that his only duty was to furnish a safe automobile and a reliable chauffeur. The other side appealed the case, however, and the higher Court said that he must not only furnish a safe automobile and a careful and reliable chauffeur, but the dealer, or his agents, must use ordinary care for the safety of passengers in order that they may be carried safely to their destination and that as the car was exclusively in charge of the chauffeur, and the passengers had no control over him, except to tell him where to drive, the dealer was liable for damages for the injuries caused by the chauffeur's negligence. —*Forbes vs. Reinman & Wolfert*, 166 *S. W.* (*Arkansas*) 563.

Killed Through Negligence

Pennsylvania Court says that motor car company is liable when one of its cars driven by one of its chauffeurs runs down and kills a man.

A woman brought an action for the death of her husband which was caused by the negligent operation of the dealer's automobile which collided with a delivery wagon driven by the husband. The chauffeur was employed by the company and had as a passenger the company's cashier who was returning after depositing some money in the bank. The Court held that as the chauffeur and cashier were engaged in the company's business at the time of the accident, the company was liable and said that they were engaged in the company's business even though they had gone three or four blocks out of their way for personal reasons on returning from the Bank.—*Witte vs. Mitchell Lewis Motor Company*, 90 *Atlantic* (*Pennsylvania*) 528.

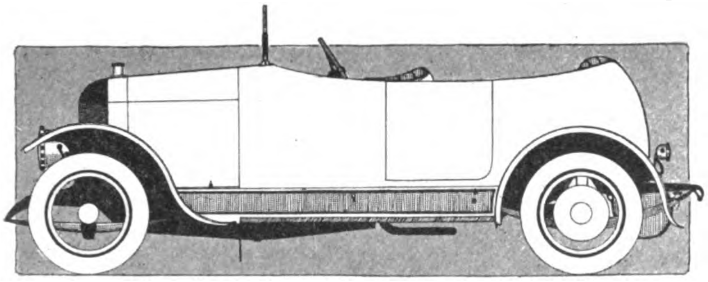

Fig. 1—Ideal car with two-door streamline body

The Rostrum

Ideal Automobile Has Six Cylinders

EDITOR THE AUTOMOBILE:—A few years ago some automobile makers got the idea that the ultimate type of car had been achieved and for one or two reasons they announced that their machines would incorporate no improvements since they were already as nearly perfect as it was possible to build them. This state of affairs did not last long, however, since the ever increasing number of improvements compelled these builders of perfect cars to change their models or get out of the game.

Today we have many different types of motor cars which resemble each other only in the kind of motive power used. By far the larger number of automobiles are propelled by the internal combustion engine and it seems reasonable to assume that this will be the motive power of the future. Dr. Steinmetz thinks the electric will be the most popular car of the future but surely the electric has not as yet reached as high a degree of development as the gasoline car and there would seem to be several obstacles to be overcome before the electric can become the universal car.

Starting with the premise that the internal combustion engine will be the motive power permit me to give my ideas as to what the car of the future will be like.

First, it will have six cylinders because this is the only type of motor which eliminates vibration and vibration spells death to any piece of machinery.

Second, it will have no hood or radiator as these parts are entirely unnecessary to the successful performance of an automobile. The motor will be air-cooled and all moving parts will be inclosed thus rendering the hood useless.

Third, it will have a simple gearset of two speeds only. More speeds on a very light, powerful six are superfluous. Possibly some form of electrical transmission such as the Entz may find favor.

Fourth, it will have some kind of wood plaster body such as has been brought out in France recently. This body will be plated with some metal, probably aluminum. One of the worst features of present day cars is the noisy, easily dented, metal bodies with their coats of perishable paint and varnish. The metal plated plaster body would overcome all these drawbacks. It would be handsome, durable, noiseless, easily cleaned and repaired.

Fifth, the car of the future will be much lighter than anything we have at present.

The present light six craze is only the beginning of automobile improvement and we have hardly begun to realize what the ultimate car must be like. Of course various other parts of the complicated piece of mechanism called an automobile will be constantly improved and no one can predict with much confidence what manner of vehicle our grandsons and great-grandsons will ride in. However, the above ideas are respectfully submitted for what they are worth.

East Canaan, Conn. D. C. CANFIELD.

A True Streamline Car

Editor THE AUTOMOBILE:—Since the word streamline seems to pervade the majority of the late automobile advertisements, it is an opportune time to remark about this wonderful new departure in motor car building.

In the first place there is only one American car made that can be called a true streamline car and the price of it is away beyond the pocketbook of the average buyer, this in no way meaning that this particular car is not worthy of the price asked for it,—but why cannot a good substantial car be built around $2,000, that is strictly up to date and embodying the features of the higher-priced cars?

There are many so-called streamline cars on the market, each and every one a perfectly good car, but the interpretation of the meaning of streamline has been misunderstood or is being withheld to be classed in 1917 or 1918 improvements. The accompanying illustration, Fig. 1, gives a clear idea of the *true* streamline body and I see no reason why this clean cut, luxurious style of body cannot be built into a $2,000 car. The industry is flooded now with cars that look too much alike, and because of the enormous production they will be on the wane before long. For this reason it behooves the manufacturers to develop the best automobile type possible, for this is the only type that will stand the reaction that is bound to come in the industry.

The car here shown is, I think, a fine example of a true streamline car. It has a four-cylinder, long-stroke motor with worm drive. The radiator is of the rounded V-type and the bonnet is quite high, which allows the use of a high-sided body yet in no way spoiling its long, sweeping horizontal lines. The upholstery is put in the car so as to be hardly noticeable, and is very thick and comfortable, the cushions of the seats resting on the floor of the body. The body is of the two-door type with the front seat divided and as a very wide body is used it makes this new feature a real comfort. The windshield is built into the cowl which joins the bonnet in a perfectly straight line. Note that there are no side lights, they being placed in the head lights so as to give the car a perfect streamline. The springs are very long and are half elliptic. Wire wheels are used.

This is a clear example of the undeveloped possibilities of body building and it is time some manufacturer grasped the situation and produced a strictly automobile type of car at a moderate price. He will be able to sell all of his product and then some.

Chicago, Ill. JULIAN F. BRASOR.

Champions Two-Cycle Motor

Editor THE AUTOMOBILE:—I noticed in THE ROSTRUM in THE AUTOMOBILE for June 18, a letter entitled Believes Two Cycle Motor Has a Future. I believe it has a "present" if the tendency in Europe means anything. The two-cycle engine has been adopted by Sulzer Brothers, Switzerland, Krupp of Germany, Carrel Grius, Belgium, Kind of Italy, Vickers of England, all reliable concerns, who have decided that a cylinder can work every stroke instead of loafing half the time, and the funny part of it is they did not make the charge to avoid valves in the combustion space either. It is also evident in the Sulzer case, that no attempt was made to eliminate parts as it has more to it than any four-cycle I ever saw. The writer has a design for an engine with features that go to raise the standard for high speed work as to power, efficiency and control and has several patentable features that will be shown soon. With only a partial test and the simplest form of motor without one change a three-cylinder, 4 by 4-inch motor developed 28 1-2 at 1,250 revolutions per minute and it can throttle to speeds as low as 185. It is a regular bull dog in power.

Cleveland, Ohio. JAMES MCINTOSH.

Reader Condemns Muffler Cutout

Editor THE AUTOMOBILE:—I was sorry to see in The Rostrum for June 25, page 1335, that the use of the muffler cutout was advocated. I have been engaged in the manufacture of automobiles for some years and have also driven them for 8 years and can see no excuse for them for any reason. The cutout is almost always abused in use and the car can be tested out just as well without it. Much of the prejudice against the automobile is due to the abuse of the cutout, and there is a large number of people whose nerves are in such a state that they are completely upset by the noise. Many of the states have a law forbidding its use on motorcycles and restricting its use on other motor vehicles; also, several of the leading makers do not equip their vehicles with them. The average driver of a car is not familiar with horses and in consequence the use of the cutout as a signal is dangerous. As a driver who is familiar with all kinds of traffic and in touch with people who use the roads I can only condemn the use of the cutout from all points of view. Another point which is least considered is the dust nuisance which is much aggravated by the cutout and also by the pipe from the muffler being directed downward.

Rockville, Conn. ALLEN HAMMOND.

—If you had read the article in question a little more carefully you would have noted that the following was said: "The unmuffled sound of a well-running motor is very pleasant to the ears of the average motorist, and this alone is sufficient excuse for its (cutout's) use, provided that the motorist does not use the device in towns or cities where the noise would be a nuisance."

We do not believe that the motorist should use the cutout anywhere that it will cause annoyance, but out in the country it does no harm and gives not only a pleasant sound, but is of some value as a signal.

Mud Pan Hard to Remove

Editor THE AUTOMOBILE:—Many motorists and repairmen will agree with me, that it is not an altogether easy job to remove and replace the dust pan of the car. For instance one manufacturer of cars fastened the pan with 8 machine bolts to the frame, and it took me and another man over an hour to remove and replace same. I would suggest that manufacturers would do away with the pan entirely and just protect the flywheel from the dirt when a leather-faced cone clutch is used.

I have noticed that manufacturers of cars do not pay the necessary attention to the construction of the universal joint. Some makers protect it with a leather cover fastened with a wire, which is quite insufficient for the wire works loose and does not keep the grease in, and every time you want to grease the joint you have to cut the wire and pull the leather back.

Some others have a metal housing which is very good but the plug hole in many cases is so located that it is impossible to reach it with a grease gun, and a grease gun is absolutely necessary to get the grease all over the wearing surfaces of the universal joint. In many cases I have fitted an elbow to bring the plug hole within easy reach. If a universal joint does not get proper attention it will wear rapidly and cause a dull knock and finally break. Manufacturers should not overlook this important feature.

DelMonte, California. FRANK H. LUMPE.

Wants Small, Powerful Car

Editor THE AUTOMOBILE:—In your issue of June 18, in which you gave an account of the Isle of Man race, a car of French design, a D. F. P., with four-cylinder motor 2.8 by 5.1 inches and rated at 15 horsepower, proved that it was fast, good on the hills and well-built.

Will you please tell me the name of the American car that answers the above description best?

Yonkers, N. Y. PROSPECTIVE PURCHASER.

—We know of no American car that resembles to any great degree the car that you mention. The best we can do is give you a list of machines equipped with four-cylinder motors of 3.5-inch bore or less, together with the names and addresses of the manufacturers and the prices of the cars.

Make and Model	Bore	St'ke	Manufacturer	Price
Carnation	3.375	3.75	American Voiturette Co., Detroit, Mich.	$ 495
Cartercar, 7	3.5	5	Carter Co., Pontiac, Mich.	1,250
Continental, 30	3.5	5	Martindale & Millikan, Franklin, Ind.	1,000
Davis, 35	3.5	5	G. W. Davis Carriage Co., Richmond, Ind.	1,335
Detroiter, A	3.5	5	Briggs, Detroiter Co., Detroit, Mich.	900
Grant, 21	2.75	4	Grant Motor Car Co., Detroit, Mich.	495
Hupmobile	3.25	5	Hupp Motor Car Co., Detroit, Mich.	1,050
Marathon, Runner	3.5	5	Marathon Motor Works, Nashville, Tenn.	925
Monarch, 4	3.19	5	Monarch Motor Car Co., Detroit, Mich.	925
Oakland, 36	3.5	5	Oakland Motor Car Co., Pontiac, Mich.	1,200
Partin-Palmer	2.75	4	Partin Mfg. Co., Chicago, Ill.	495
Paterson, 33	3.5	5	W. A. Paterson Co., Flint, Mich.	1,200
Read, 30	3.5	4	Read Motor Car Co., Detroit, Mich.	850
Saxon	2.625	4	Saxon Motor Co., Detroit, Mich.	395
Studebaker, 4	3.5	5	Studebaker Corp., Detroit, Mich.	1,050
Vulcan, 27	3.375	5	Vulcan Mfg. Co., Painsville, Ohio	750

To Attach Hartford Shock Absorbers

Editor THE AUTOMOBILE:—1—Please explain how I could place Truffault-Hartford shock absorbers on my Hupmobile 32? Use sketch showing where to attach them on rear spring.

2—Would you advise installing them on this car? Do you know of a shock absorber that would give better results than the Truffault-Hartford?

Cleveland, Ohio. THOMAS LINLEY.

—1—Drawings showing the method of attachment of these shock absorbers to the Hupmobile 32 are given in Fig. 2. At the left the installation of the shock absorber on the rear of the car is illustrated, and at the right the front shock absorber is shown attached. The front shock absorbers are attached in the ordinary way, that is, lengthwise of the car,

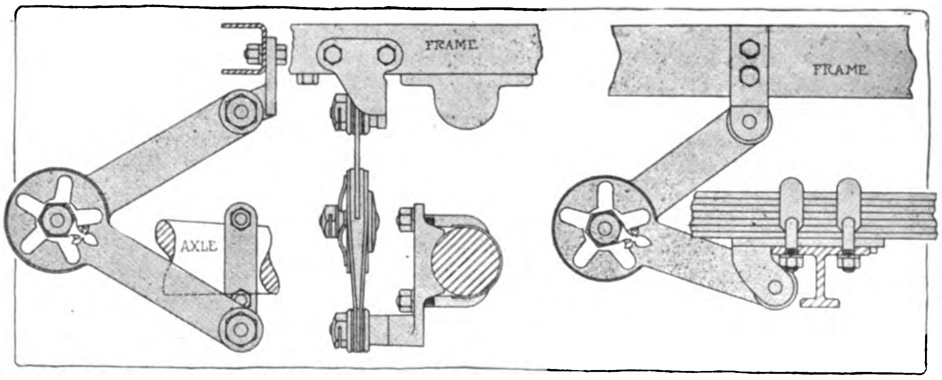

Fig. 2—Method of attaching Hartford shock absorbers to Hupmobile 32. The attachment of the rear pair is shown at the left and the front pair at the right

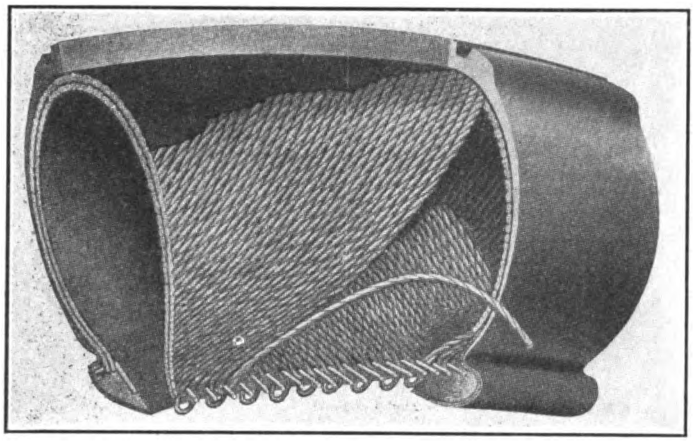

Fig. 3—Construction of Goodrich Silvertown Cord tires

but in the rear they are attached cross-wise because a transverse spring is used in the rear.

It will be noted that in putting on the rear shock absorbers two holes are drilled in each side member of the car frame and that a bracket on the upper arm of the shock absorber is bolted to the frame at this point. The lower arm of the shock absorber is clamped around the axle as indicated.

Likewise, the upper arm of each front absorber is attached to the frame by a bracket held by two bolts while the lower arm is attached to the axle by means of a bracket that goes between the spring and the axle.

While the attachment of these shock absorbers is a simple matter, there is no reason why you should attempt it as this will be attended to by the agent that sells you the shock absorbers.

2—Just as we have stated many times before we cannot advise any of our readers as to what is best and what is not best. In order to give authoritative opinions on such questions as this one you have asked we would have to exhaustively test every automobile and accessory brought out, and obviously this is impossible. Yet it would not be fair to either our readers or the manufacturers if we based conclusions on anything less than the results of long and careful tests. It certainly would not be right to give advice based on our own opinions after seeing these devices in action, or after reading the catalogs or on somebody's unreliable advice.

Cord Tires Take Less Power

Editor THE AUTOMOBILE:—I notice in June 4 issue you mention that cord tires were used in the big race, at Indianapolis. How do they differ from the ordinary tire and how much higher priced are they? Would it be an advantage to use them for country roads?

2—On page 1170 of the same issue you mention a 13 to 37 gear ratio for a Ford. Would not this be much stronger and also give a car more power? Where could I buy it?

Plentywood, Montana. JOE A. KAVON.

—The Cord tires differ from the ordinary tire in that instead of using a fabric of canvas cloth to hold the pressure a cotton cord construction is employed. Fig. 3, shows the construction of the Goodrich Silvertown cord tire.

It is claimed for these tires that they are more resilient, flexible and stronger, and less liable to rim-cutting. The greater flexibility means that less power is required to drive the car and the increased strength augurs more life and less liability to blowouts. It is claimed that a saving of 25 per cent. in fuel is possible.

As will be noted in the figure, the carcass of the tire is made up of a number of individual, long fiber cotton threads thoroughly impregnated with rubber under high pressure; these threads are then woven into a cord which is also impregnated with rubber. The finished cord is then woven over a form, in two layers, each layer of cord being separated by a layer of rubber. Every part of the cord is made and wound into the tire under equal tension by specially designed automatic machinery in such a manner that all internal strains are conveyed throughout, with no slack threads and no overworked parts. Every part of the tire carries its share of the load and all parts work together as a unit.

The cord tire costs about 25 per cent. more.

2—We do not quite understand what you mean by the gear ratio being stronger. There is little difference in the strength of the pinions and gears but this gear ratio will give the car greater speed but less hill-climbing ability.

This gear ratio will have to be made specially. Any first class machine shop should be able to do this work.

Route from Bethlehem, Pa., to Boston

Editor THE AUTOMOBILE:—Will you please tell me what is the best road, scenery considered, from Bethlehem, Pa., to Boston, Mass

South Bethlehem, Pa. E. CIARLO.

—Probably the best way is through New York City. Drive through Easton, Clinton, Whitehouse, Bound Brook, Plainfield, East Orange, Newark, Hoboken to New York City. Then turn north, following Broadway to 207th street, then turn to right and cross the Harlem. Keep straight ahead until Fordham road is reached and follow this into Pelham Parkway, which is a continuation. Follow main road passing through New Rochelle, Larchmont, Mamaroneck, Rye, Portchester, Greenwich, Stamford, Darien, Norwalk, Westport, Southport, Fairfield, Bridgeport, Stratford, Milford, Woodmont, Savin Rock, New Haven, Meriden, Berlin, Hartford, Springfield, Palmer, Worcester, Marlboro, Waltham, Boston.

How to Make a Keyway Quickly

Editor THE AUTOMOBILE:—So few mechanics, not to mention amateurs, know how to cut a keyway properly, that I believe it would be worth while to note these simple operations. After laying out the keyway, Fig. 5, with a scratch awl, rough out the keyway with a cold chisel which should be just a trifle narrower, in width, than the finished keyway. This can be done very quickly with a good sharp cold chisel. The angle at which the chisel should be held is indicated in the figure. The keyway is then finished with a sharp, square cornered file. The points to be most careful about are to file to uniform depth and to maintain a uniform width from one end to the other.

New York City. W. F. SCHAPHORST.

Weight of Car Increases Tire Pressure

Editor THE AUTOMOBILE:—1—Is it easier to pump up a tire with the wheel jacked up when the weight of the car is resting on the wheel?

2—If a gauge shows a certain number of pounds with the wheel jacked up, will it show differently when the weight of the car is resting on the wheel?

Macon, Miss. M. H. HARRISON.

—1—Theoretically it is slightly easier to pump up a tire when the weight is removed but the difference is so small that it is doubtful whether any ordinary gauge would measure it. The extra work required represents the amount of work to lift the weight on that wheel through the distance that the inflated tire lifts the rim off of the ground, this distance being approximately 3 inches. But this is divided up among so many pump strokes that the extra work is not felt, and it is probably just as economical of energy to do it this way as to jack the wheel up.

2—When the weight of the car is placed on the fully inflated tire the pressure increases slightly, but not enough to register on the ordinary gauge. In considering what happens when the tire is let down off the jack it is well to keep in mind that under these conditions the pressure of the air in the tire at any time multiplied by the volume of the air in the tire at the same time is equal to a constant quantity. Therefore if the pressure in the tire when it was up on the jack was 70 pounds and the volume 1,000 cubic inches then when the tire is made to support its part of the weight of the car, the tire bulges slightly, Fig. 4, and this reduces to a slight extent the cross-sectional area of the tire at the bottom and therefore reduces the volume slightly, possibly not more than 1 cubic inch.

Since the volume has been reduced 1-1000 the pressure will be increased the same amount or to 70.07 pounds.

Definition of Piston Displacement

Editor THE AUTOMOBILE:—1—Please explain in your next issue what piston displacement is, how to measure it and

2—What is the displacement of the Chalmers 30?

St. Louis, Mo. A. F. K.

—1—Piston displacement means the actual number of cubic inches displayed by the movement of all the pistons from one end of the stroke to the other. Considering just one piston, it equals the area of the piston head in square inches multiplied by the length of the stroke in inches, and in a four-cylinder motor, for instance, the total displacement would be four times this amount.

The area of the piston head is equal to the bore of the cylinder squared and then multiplied by .7854 and the volume is then given by multiplying this by the stroke. This gives the displacement of one cylinder, and therefore to get the total displacement, it is necessary to multiply by the number of cylinders.

Expressed as a formula:

Piston displacement $= \text{bore}^2 \times .7854 \times \text{stroke} \times \text{number of cylinders}$.

2—The dimensions of this motor are 4 by 4.5 inches and applying the above formula, we have,

Piston Displacement $= 4^2 \times .7854 \times 4.5 \times 4 = 228$

Spark Retarded May Heat Motor

Editor THE AUTOMOBILE:—It has been suggested to me by a reader of your publication to write regarding the heating of my automobile engine. It seems that the motor heats too much and that the thermo-syphon system does not do its work properly or that the heating is caused by another source. I believe my carbureter is adjusted properly, there is no slipping fan belt or loss of compression, but still the engine overheats. As the car has not been run over 3,000 miles, I doubt as to whether carbon could be the cause.

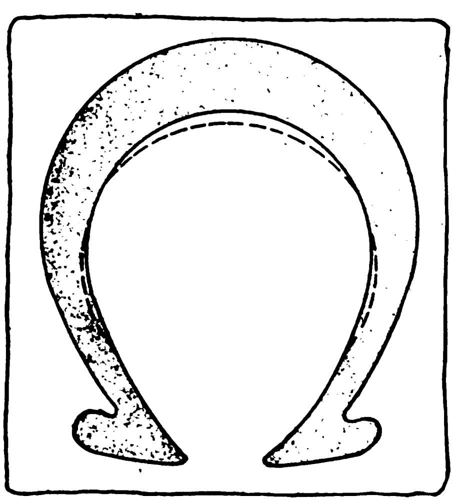

Fig. 4—Section through tire, showing decrease in cross-section when it is carrying the weight of the car

W. F. DEHNERT.
Newark, N. J.

—It is most likely that your trouble is due to driving with the spark retarded too far, although it is impossible to say with certainty that this is so.

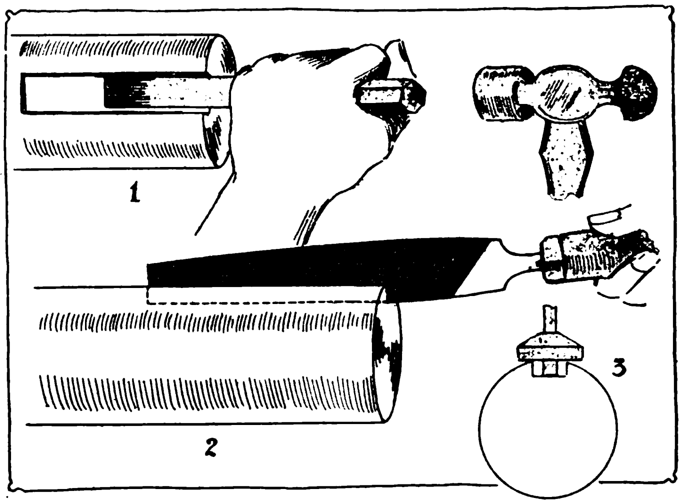

Fig. 5—(1) Method of cutting keyway. (2) Filing it smooth. (3) Measuring depth of keyway

Try driving your car with the spark advanced as far as possible, at all times, without the motor knocking.

There are many other things that might cause your motor to overheat, however; carbonized cylinders, poor water circulation, incorrect timing of motor, dragging brakes or possibly excessive friction. Just as you state, it is not likely that the trouble is caused by carbon but in looking for the cause it is not wise to neglect this possibility for the reason that motor troubles are often caused by the most unexpected circumstances.

Note whether the water is circulating freely, and if not, try to find where the trouble is, whether it is due to dirt, loose pieces of rubber obstructing the passages or what not.

Remember that with a thermo-syphon system, the water will not circulate at all as soon as the level drops below the discharge header in the top of the radiator. Circulation of water in the thermo-syphon system is dependent on the fact that the column of water, considered as such for simplicity, in the pipes and water jackets, is lighter than the column in the radiator because it is warmer and water expands and grows lighter as it is warmed. Therefore, if the level of water drops below the outlet pipe, circulation must stop. Consequently it would be well to note whether you have not been running with the water below this point. Or it is possible that you have a slow leak and that in the course of an afternoon enough water leaks out to lower the level enough to stop the circulation, as described.

If there is dirt in the radiator flush it out thoroughly and if there is any grease in the water wash it with a hot solution of sodium carbonate in water, one handful of carbonate to a pail of water will be sufficient. See that the rubber hose connections are in good condition.

As a last resort, check up the valve-timing by the marks on the flywheel and if there are no marks you had better write to the maker for information on this point.

You do not say whether your water boils or not although it is generally understood that this occurs whenever it is stated that a motor overheats but from your description it seems possible that, while the motor and especially the radiator becomes very hot to the touch, no boiling and therefore, no actual damage occurs, no loss of power is noted and there is no difference in the action of the motor or the performance of the car. If this is the case, there is nothing to worry about. A gasoline motor is designed to operate with the water very near the boiling point, or in other words at about 180 degrees Fahrenheit and although this temperature seems hot to the touch, it does not harm the motor.

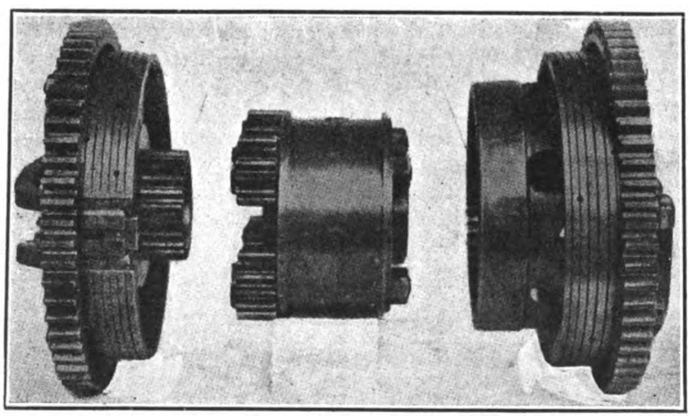
You have given no symptoms of overheating but merely stated that the motor "heats too much" and if the motor does not lose power or knock, there is nothing the matter.

The Engineering Digest

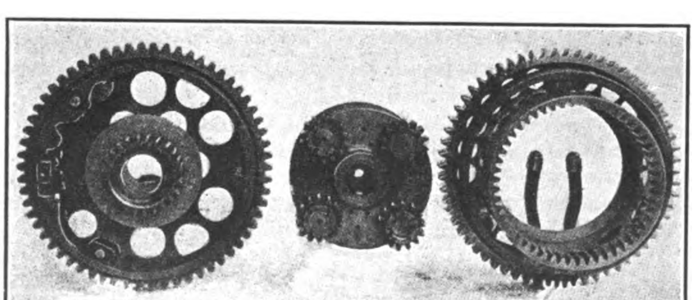
Worm Drive with Planetary Three-Speed Gear Forming a Rear Axle Unit—Tested Several Years

TWO difficulties stand against the adoption of a planetary change-gear for automobiles; first, that the sliding-gear has become almost universally adopted for cars requiring more than two gear-speeds ahead and, secondly, that the arrangement of three or four gear ratios so proportioned that the motor can be utilized fully on all of them is found difficult to make, because the sizes of the planetary gear wheels are somewhat interdependent while the peculiarities in the meshing of an internal gear also limit the choice of dimensions. A third difficulty arises if it is desired to place a planetary gear on the rear axle, as its weight is considerable and forms an unwelcome addition to the unsprung mass of the running-gear of the vehicle. Nevertheless a planetary gear with three forward speeds and reverse has been in operation in several hundreds of cars turned out during the past seven years by Chambers Motors, Ltd., of Belfast, Ireland, and for the past five years it has been located on the rear axle, forming a construction unit with a worm drive and the differential.

With a view to the revision of standard construction data which is now taking place all over in order to exploit all possibilities for building very light cars and cyclecars at a low cost of production, and also with an eye to the simplification, improvement and cheapening of trucks and delivery wagons, the Chambers planetary gear and the substantial details of its construction have become matters of timely interest, rather enhanced by the length of time it has been in practical use, and *Engineering* (London) gives an elaborate description of the latest model, from which the following abbreviated account and illustrations are taken.



Figs. 1 and 2—Two gear-speed members of Chambers gear and differential box with planet pinions



Change Gear Between Vehicle Wheels and Worm

In the general design it is first notable that the change-speed gear comes behind the worm gear in the order of power transmission, so that the speed and driving-pressures of the latter remain unaffected by gear changes. The drive is transmitted from the worm wheel to the drum upon which this wheel is mounted and from this drum through expansion rings to one or the other of the two speed-gear members, one of which comprises the internal-gear ring and the other the central sun gear, and from either of these gears the differential box is driven through the planetary pinions; the wheel shafts finally are driven from the differential box in the usual manner.

Figs. 1 and 2 show the two speed members with their expansion rings and the differential box with the planetary pinions, while the mechanical means employed for assembling these parts within the worm wheel drum and the outer drum, as well as the control parts and the external reverse gear pinions, are distinguishable in the line drawings, Figs. 3 to 7. The grooved pulley-like parts shown in Fig. 1 are actually the outer surfaces of the expansible friction rings, which lie inside the outer drum carrying the worm wheel and are marked *b* in Fig. 5. These friction rings may be expanded either separately or together, this giving the three gear combinations, of which the one caused by clutching both rings is the direct drive. The external teeth on the speed members, which makes them look like large spurwheels, have no share in forward propulsion but come into action for the control of the friction rings and for the operation of the reverse. The drum carrying the worm wheel is for the sake of clearness shown double-cross-hatched in the line drawings. When one speed member is clutched, the other is locked automatically by means of a pivoted catch, referred to later, and on direct drive this special locking mechanism is out of action.

The Gear Ratio

For the first speed, the speed member with the internal gear, and marked *c* in Figs. 3 and 5, is locked, while the friction band of the member with the sun gear, marked *d*, is expanded and driven by the worm gear. For the second speed this is reversed, *d* being locked while *c* is driven.

It is this mutuality in the gear arrangements which is generally resorted to in planetary gears in order to get two different speeds without too many parts and which in turn makes it difficult to get the proportions in the gear ratios what they should be. But with as much effort expended upon planetary gears as has been devoted to sliding-gears this drawback may perhaps be circumvented.

In the present instance the sun wheel has 24 teeth, the internal wheel 52 teeth and each of the planets 14 teeth. These proportions give driving speeds for the vehicle of about 8, 17.5 and 26 miles per hour with the motor running at 1,100 revolutions per minute and the proportions of the worm drive such as they are in the Chambers car. The gear ratios apart from the worm drive may be figured as follows: With the first speed in action, the internal gear is locked, as mentioned, and the sun gear *d* drives the planetary pinions e. One revolution of the internal gear now in the first place produces one revolution of the sun gear by turning the four planetary pinions, as a unit, once around, the sun gear following, and secondly the revolution of the pinions on their own axes causes an additional revolution of the sun wheel determined by the number of teeth, 52 in the internal gear and 24 in the sun wheel, so that the total rotation of the sun wheel becomes 1 plus 52/24 revolutions, making 3.16 revolutions. As one revolution of the internal gear on the first speed is also one revolution of the vehicle wheels, the gear ratio on this speed is thus 3.16. The ratio for the second speed, when it is the sun wheel which drives, becomes by similar reasoning 1 plus 24/52, which is 1.4615. The third speed, being direct, is of course unity, both the internal and the sun gear driving the pinions but in opposite directions, so that they cannot revolve on their axes.

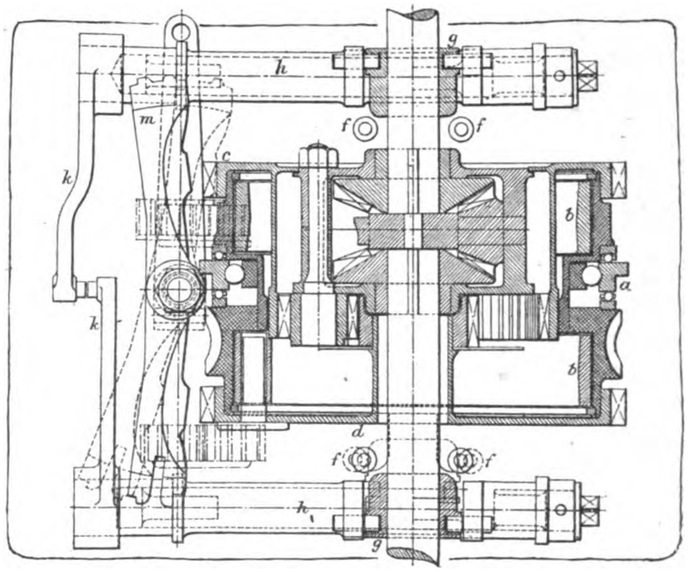


Fig. 5—Horizontal section; locking bar in position for either direct drive or reverse, being out of action

Operation and Control

The operating mechanism is perhaps the most interesting part of the Chambers gear. Each of the expansion rings, Fig. 6, is operated by means of a forked and rotatable clutch lever formed of two similar parts, the ends of which are shaped to carry rollers f and straddle the car axle without touching it. The formation of each part is shown to the right of the friction ring, Fig. 6. The friction rings are expanded when the free ends of the clutch levers are forced apart by a collar which slides on the central wheel shaft, as shown at g in Fig. 5, and the collars—one on each side of the mechanism—are controlled by two hollow rocking-shafts shown at h in Figs. 3 and 5. Each rocking-shaft has two upward-projecting arms which form a fork between the prongs of which the collar rotates, and pins with flat elongated heads are carried by the arms and serve to move the collar along the shaft. Levers shown at k in Figs. 3 and 5 and separately in Fig. 7 are pinned to the hollow shafts and these are connected to the pedals in front of the driver, so that he can move either or both collars. The motion of the rocking-shafts is spring-controlled, the foot pressure forcing them outward against the spring tension. The springs are inside of the hollow shafts, as shown in dotted lines in Fig. 3 and are arranged to be adjusted without dismantling the gear.

The details of the connection between the prongs of the clutch levers and the friction rings are worked out elaborately and are shown in Fig. 8 ou a large scale. The parts marked f are here the ends of the clutch levers. Each of these prongs is formed with a rocking-edge l on its inner face and a feather r on its outer, the feather fitting into a groove in the friction ring. The groove is lined with a hard steel seating. Between the two prongs there is a distance-piece made up of three parts, the inner one of which is wedge-shaped, and this distance-piece forms an adjustment for the friction ring; by slacking the wedge or tightening it the diameter of the ring is altered. The expansion necessary for clutching one of the speed members is obtained, as already explained, by rocking the prongs by means of the collar which forces apart the other ends of the lever arms. By this operation the feathers on the outer sides of the prongs are moved slightly upward and carry the ends of the friction bands with them. The whole arrangement is held together by the flanges on the distance-piece, the pins through the clutch levers and the inward spring of the ring, and the clutch levers are in no

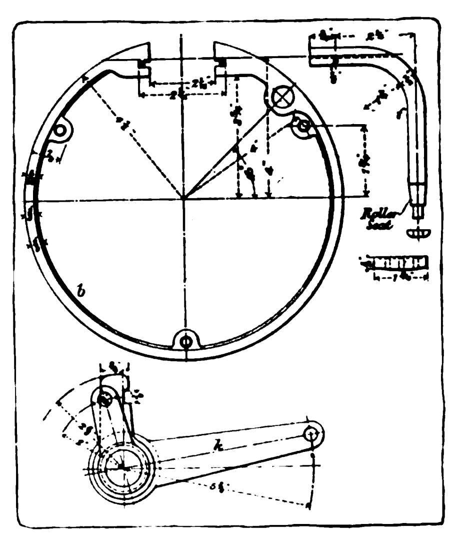

Fig. 6—Expansible clutch ring, with one member of clutch lever. Fig. 7—Bell lever k

other way secured to any part of the whole mechanism.

Locking of the Idle Speed Member

To lock the non-working speed member, while the other drives, the pivoted bar shown at *m* in Figs. 4 and 5 is provided. The range of motion of the bar is indicated in Fig. 4, the opposite motion being equal in extent. It locks by engaging with the outside teeth of the speed member. The bar is moved by lever *n*, Fig. 4, which is connected to the hand gear and it is interlocked with the mechanism for operating the collar *g* by catches on the rocking-shafts *h*, the catches engaging with the stepped ends of the bar, as at *p*.

The Reverse Gear and the Casing

To reverse the direction of the drive, a gear of the sliding type is employed, composed of spurwheels engaging on the outside of the speed members; see Fig. 3. When it is in mesh, the sun wheel drives from the outer worm wheel drum and the internal gear wheel is revolved backwards. The locking bar is out of action. The train of pinions for reverse is proportioned so that the internal gear makes one revolution for every 1.5 reverse turn of the sun wheel.

The whole mechanism is enclosed in an aluminum casing to which are secured the hollow fixed axles inside of which the wheel-driving shafts float, and the radial and thrust ball-bearings for the drive shaft as well as the very large ball-bearing for the worm wheel are mounted directly in this casing. A ridge is formed upon the outer fixed member of this bearing and fits into a corresponding groove in the aluminum while also acting as part of the two ball thrust-bearings taking the end pressure of the worm drive.

Rules for Hotelmen Who Want to Hold Motor Tourist Trade

FRENCHMEN do not like to tour outside of their own country, as a rule, but they admit that the hotels in out-of-the-way places in Switzerland and Holland give more acceptable accommodations than those to be found in some of the French provinces. The *"Club des Cent"* is an exclusive association, recruited from those prominent in art, politics and commerce, which has for one of its purposes to guide French hotelmen to a better understanding of the requirements for securing the best tourist trade. Each member must have driven his own car at least 40,000 kilometers, and all are constituted "overseers of the roads" and report on their condition. At the club there is a book in which the members write their reflections and their desires, and it is now the intention to have some of these remarks printed on cards and sent to hotelmen, to be posted in their private offices, and as folders for general distribution

Among the remarks in the club book bearing on the hotel question the following give an idea of the movement. They are largely in the form of mottos:

To Hotelmen

"Cleanliness, sane nourishment, fresh beds; luxury afterwards."

"Make us pay the price of things; we want you to earn a generous living; but we refuse absolutely to be gouged."

"No special affection for the 'Majestic Palace' or for mahogany barracks: as a rule, the larger the hotel, the more its kitchen flirts with chemistry."

"In a hotel you find often a good landlord, seldom a good manager."

"The club favors especially the good little hotels, the good little inns managed by their owners."

"In a good hotel one is received by the landlord."

"We eat beefsteak, not Louis XV armchairs."

The French Kitchen

"Good French cooking is done with fresh ingredients: fresh greens, fresh eggs, fresh butter, fresh milk."

"Let the salt be served in closed shakers, the pepper likewise; no dry mustard on the edge of the container."

"A good hotel is known by its coffee; no chicory! Coffee is made slowly with boiling water. Any coffee made in advance is poor coffee."

"Sugar bowls with covers; biscuits in closed boxes; cheese under cheesebells. Feed your guests, not the flies."

"The French kitchen ignores the soups bought in bottles or tins at the grocer."

"Down with gelatine! Down with fish glue! Any jelly made with gelatine is a nest for microbes. No chemical extracts! no sauces turned out at food factories! We admit no other kitchen than the kitchen."

"The great kitchen is not always the good kitchen. Down with the schools of cookery invented in countries where they don't know how to eat."

"Buy good wine. Having bought it, learn how to keep it. The hotelman who does not keep a few select bottles in his cellar cupboard is only a hashhouse keeper."

The Personnel

"Get your help in your own country: The Club of the Hundred refuses to stop with hotelmen who employ people with bizarre accents; Swiss in Switzerland, Italians in Italy, French in France."

"You little hotelkeepers, don't degrade your waiters with soiled clothing; any garment is good if it is clean."

"White linen, washed hands and combed women."

"A chauffeur should eat at the same time as his employers; he should be received as well as they are."

Rooms

"Clean, light rooms, large and comfortable bed, plenty of water."

"Buy everything in your own section of the country; Britton crockery and furniture in Brittany, Normandic furniture in Normandy; be at home; save the local color. Down with the products of the international market!"

New System for Swimming Pool at French Club

WHEN the Automobile Club of France built a new swimming pool at the clubhouse it also adopted a new system for keeping it clean and fresh. It is described at length in *Construction Moderne* of March 8 by Mr. Couturaud.

The principle for the installation is to make the same water circulate constantly; from the pool to the filters, the sterilized apparatus operating with ultraviolet rays, the reheater, the circulation pump and back to the pool. The reheater does not receive all the water in circulation but only a fraction adjusted according to the temperature to be obtained. The degree of heating produced by the apparatus remains constant.

The dimensions of the pool are about 25 by 9 meters with a useful depth of 3½ meters. It is built of armored concrete on the level of the street, and the machinery is in the sub-basement.

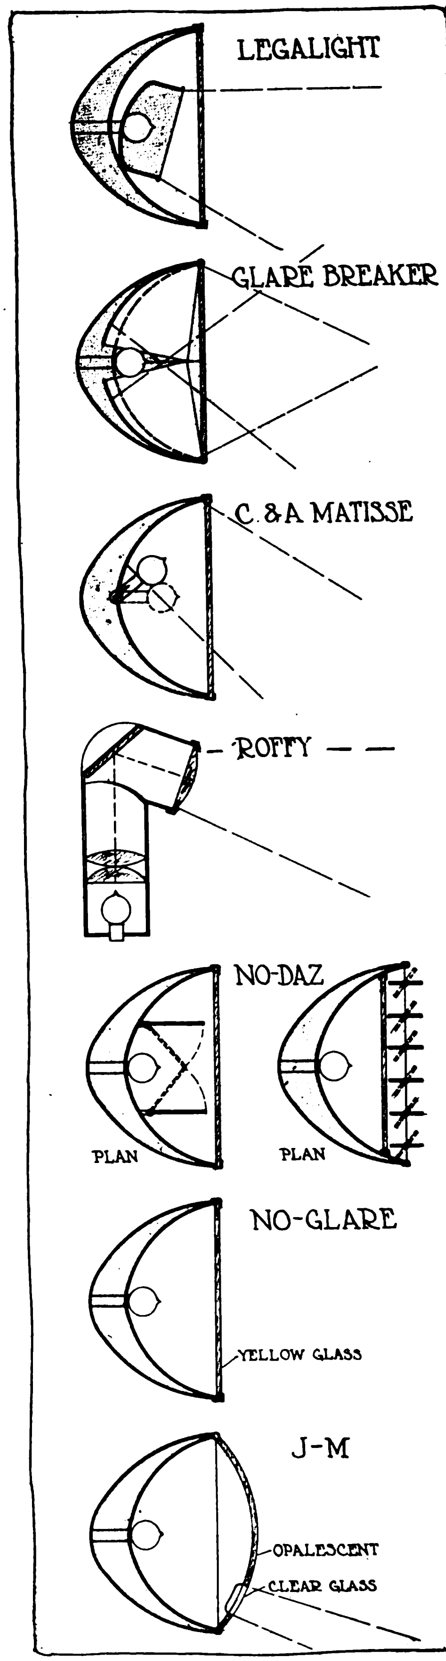
The water can be driven by the pump either into the sewer or to one of two sand filters. These filters are cleaned from time to time by means of a counter-current of clean water which carries away the impurities, the sand being churned up at the same time with rake-like instruments.

The sterilizer, which acts upon the water after it has been filtered, consists of a mercury vapor lamp with quartz bulb around which the water circulates.—From *Génie Civil*, June 20.

Metropolitan S. A. E. Discusses Headlights

NEW YORK CITY, July 3—At a meeting of the metropolitan section of the Society of Automobile Engineers, held at the Automobile Club of America last night, the subject of non-glaring headlights was taken up. All the known manufacturers of devices for eliminating the glare from headlights were invited to demonstrate their devices before the metropolitan engineers and seven responded. These were as follows:

1—Legalight Mfg. Co., New York City.
2—Glare Breaker Co., Pittsfield, Mass.
3—C. and A. Matisse, New York City.
4—Pittsburgh Electric Specialties Co., Pittsburgh, Pa.
5—Ward Leonard Co., Bronxville, N. Y.
6—Corning Glass Works, Corning, N. Y.
7—H. W. Johns-Manville Co., New York City.



Illustrating the seven types of headlight glare-removing devices exhibited to Metropolitan Section of S. A. E. at the Automobile Club of America.

Legalight

The Legalight was described by Joseph Gries. It consists of a small reflector which can be clamped over the bulb by a simple attaching device whenever it is desired to have the lights subdued. The Legalight deflects the rays 15 degrees from the horizontal so that the light falls on the ground in front of the car. At this angle the axes of the light cones are thrown on the road 3.73 feet in front of the car for every foot of height of the lamps. That is, if the lamp is 3 feet above the ground, the center of the stream of light would strike the ground 11.19 feet ahead of the car, illuminating the path ahead. The small reflector is deeply cupped as it was found that if the cup were not deep enough some of the rays would get into the main reflector and would be thrown straight ahead, giving the dazzling effect.

Glare Breaker

The Glare Breaker, as described by J. G. Middleton, of Pittsfield, Mass., is a device which splits the reflector of the lamp exactly across the center. This destroys the parabola and instead of the beams being thrown straight ahead they are deflected downward in front of the car and upward at an angle which is sufficiently acute to remove any danger of the rays striking the eyes of pedestrians or of occupants of oncoming cars. The rays which are thrown from the upper part of the split reflector strike the ground in front of the car and serve to illuminate the road ahead. The device is controlled from the seat of the car and can be operated when another car approaches or whenever it is desired to break the headlight rays by pressing a button which controls a solenoid coil.

C. & A. Matisse

Norman Macbeth, exhibitor of the C. and A. Matisse, in lecturing on the headlight situation, spoke of the cause of glare as being the filling of the retina of the eye with the rays of light. That is, when the retina is filled by a large volume of light, the blinding effect is given. The C. and A. Matisse is a device which can be controlled from the seat and consists simply in a means for removing the lamp bulb from the focal point of the parabola. The bulb socket is pivoted and when it is desired to cut down the direct rays in order to eliminate the glare, the bulb is tilted upward out of focus. This immediately annihilates the effects of the parabolic reflector and the rays are scattered instead of thrown forward in a direct dazzling beam.

Roffy Achromatic

The principles of the Roffy achromatic lamp were explained by J. G. Roffy. The glare-eliminating properties of these lights are due to the inclination of the axis of the light cone so that the uppermost rays are parallel to the ground. According to Mr. Roffy, the best arrangement is to have this ray at a height of 4.5 feet. This would eliminate the possibility of the blinding of either a pedestrian or occupant of another car by the light. The sectional illustration shows the arrangement of the lenses within the lamp, the light being deflected ahead by a diagonal mirror. Immediately above the high-candlepower bulb there is a plano-convex lens that concentrates the light and throws it into the double lens above it. From this lens the light is thrown against the mirror and thence through the projecting lens in front which neutralizes the color distortions produced by the condensing lens. In connection with this lamp there is a series-parallel switch which cuts in half the amperage when thrown into series.

No-Daz

Leonard Kebler, president of the Ward Leonard Company, described two devices that are made under the name of No-Daz. The first of these has a pair of translucent wings fastened inside the reflector. These wings project forward from the reflector in ordinary running, but when it is desired to dim the lights they fold tightly across the face of the reflector, imprisoning the light within. In the second scheme there is an arrangement at the front of the lamp similar to the ordinary shutter on a window. In ordinary running the shutters stand horizontally with the light shining between their faces. As the edges of the shutters are very thin, but little light is absorbed by them. When a button is pressed from the driver's seat the shutters are closed and the glare removed.

No-Glare Glass

The No-Glare glass made by the Corning Glass works was described by Dr. Wm. Churchill. The doctor was the first one to take up the non-blinding headlight from a physiological rather than a mechanical standpoint. He stated that the glare was caused mostly by the presence of rays near the violet end of the spectrum and that the rays at the red end of the spectrum do not materially affect the eye. "The glare is most," he said, "when the intrinsic brilliancy is highest." He then went on

The French Race

EUROPEAN manufacturers had their first opportunity last Saturday of observing the performance of 274-cubic inch motors in a 467-mile road race, the roads over which the race was run having in some places an average of forty curves to the mile and in other places having other road conditions such as crowned centers that severely tested these new racing creations.

From THE AUTOMOBILE'S cable reports it is apparent that these little speed creations made good, and if 65.5 miles per hour is rather slow compared with Indianapolis records for 500 miles it must be remembered that a tortuous 23-mile road circuit is much different from the brick speedway where racers travel with wide-open throttle most of the time.

That eleven of the thirty-eight starters completed the French contest within the time limit set is proof that the small motor has made good.

THE DOMINANT QUESTION REGARDING SATURDAY'S CONTEST IS, "WHAT GOOD DOES IT DO THE INDUSTRY?"

To those who began nearly a year ago building these special cars to a 274-cubic inch piston displacement and a maximum weight of 2,425 pounds, the race has many lessons. The winning Mercedes has made important discoveries in the matter, so far as the company is concerned. Last year it raced six-cylinder cars and this year it built both four-cylinder and six-cylinder machines to meet the race conditions. For months before the race both models were given strenuous road tests and the four-cylinder emerged a winner. The value of careful testing was shown by the results, this company winning the first three places.

But the race has done more: It has developed the overhead-valve construction as never before. Only one make of car contested that did not have overhead valves and it used sleeve valves. Last year several companies believed they could build T-head or L-head motors with small displacement to give the necessary high crankshaft speeds, but they discovered the error of their ways and this year all adopted some form of the overhead-valve design.

There is not anything new in using the valves in the head. They were more popular in America 8 years ago than today, but the past winter has seen one or two new models of small-displacement motors brought out using this form of valve arrangement, and these are to date giving good results. Saturday's race has given some good examples of how compact valve arrangements can be obtained; of how it is possible without much difficulty to satisfactorily inclose the entire valve mechanism, thereby making lubrication a simple problem and eliminating the noise factor. It is certain that the overhead-valve motor will receive more attention because of this race.

From a motor design viewpoint, Saturday's contest has proven that high crankshaft speeds are largely obtained through very careful balance of motor moving parts and light weight. Pistons turned from the best forging obtainable were cut to a wall thickness of 1/25 inch, and this proved satisfactory; connecting-rods were reduced; crankshafts received more attention than they have ever before received; shafts made from as many as four different parts were used and the performance of some of these has demonstrated that microscopic accuracy in construction has its merits in reduced vibration and naturally greater stability.

The French deserve credit in placing a maximum weight limit on the cars entered. For years we have labored in America with minimum weight limits and several years ago some of our leading low-priced cars were barred from contests because they were too light. Fortunately those days are over and our designers can no longer claim that a car must have weight in order to keep on the roadway. It is not weight that keeps a car on a partially crowned roadway but many engineering factors enter into the work. The careful division of weight over the axles, the suspension, the design of axle parts, the balance of wheels and other rotary parts, the balance of motor, etc., all add their quota in making a car that will hold the roadway at high speeds.

WE MUST KEEP IN STEP WITH PROGRESS, AND THE DAY IS PAST WHEN WEIGHT CAN BE USED AS A RATIONAL ARGUMENT FOR MAKING A MOTOR VEHICLE SAFE ON THE HIGHWAYS.

Gasoline Substitute Manufactured for 2 Cents per Gallon

Tests at Indianapolis Demonstrate That Fuel Made of Moth Balls and Water Has Same Properties as Gasoline

INDIANAPOLIS, IND., July 4—Making gasoline for 2 cents a gallon out of moth balls and water may seem like a dream but that was just what was done at the speedway today. There were some other ingredients, but the white powder, napthalene, out of which moth balls are made, and river water formed the principal part of the mixture which was poured into an old soap kettle out of which came a motor fuel, which, if it was not gasoline, had all the properties of that popular liquid except the smell.

John Andrews says it is gasoline, and he should know because he is the man that invented it.

Synthetic gasoline, that is, gasoline made by combining its elements through laboratory processes is not unknown. It has been accomplished before, but always has cost very much more to produce than if it were distilled from crude petroleum in the usual way. It was the general impression that until the price of gasoline rose a great deal higher than its present figure, no synthetic fuel of this sort would be commercially practicable.

This impression was upset completely in the minds of a dozen engineers when there was unloaded from the tonneau of a touring car, at the speedway, the bottom of a base burner, an old soap kettle, a funnel-shaped hood that fitted over the kettle and some odds and ends of iron piping. The touring car with its load had just arrived from McKeesport, Pa. The whole apparatus possibly could have been purchased from any junk man for the sum of $25, but when it was set up in one of the wooden garages that housed a racing car a month ago the junk heap assumed the form of a very complete still.

The apparatus was in shape for operation in the afternoon, and into the soap kettle was poured about 15 gallons of what the inventor called soup.

This is simply the residue from two or three previous runs in McKeesport, and was used to give quick distillation. It was not gasoline, and could not have had much gasoline in it because it could not be made to burn; nor was there any oil about it. It seemed more like dirty water than anything else. Then 5 gallons of water from the speedway mains was added, followed by about a half cupful of ammonia and a quart of powdered napthalene. The inventor here became quite mysterious and refused to divulge the names of the other constituents. However, he added to the mess in the kettle, about 2 ounces of some clear liquid, then a half cupful of a dark yellow liquid that made a quantity of smoke, and finished by dropping a pinch of some powder into a sort of cross between a whistle and a safety valve on the top of the gooseneck of the still. Then a moderate fire was lit under the kettle and there was nothing to do but await results. How many of the mysterious powders and liquids that went into the kettle were necessary and how many were put in to protect the secret, it is impossible to say.

Process Takes 1 Hour

Twenty minutes after the fire was lit, the still began to give off a great deal of inflammable gas and in just 1 hour a very light colorless liquid began to run out. This was collected in a glass water bottle of 5 gallons capacity. By the end of 2 hours more the water bottle was full. Its contents showed a gravity of 70 degrees Baumé and when poured into a special tank on a National six with a Rayfield carbureter, acted in every way the same as gasoline. It was found possible to increase the proportion of air very considerably.

Today the still was put in operation again. But this time, instead of using the soup, about 20 gallons of water were put in and a larger proportion of the chemicals. The product today had a gravity of 64 degrees Baumé.

A series of exact tests were made on the product by Carl G. F. Fisher and a committee of engineers, including Howard Marmon and Walter Marmon of the Nordyke & Marmon Co., Hanch of the Marmon company, Darwin S. Hatch of *Motor Age*, and others.

A six-cylinder National, weighing 3,800 pounds ran 12.5 miles on the speedway on a measured gallon of the product and showed a flexibility on high gear of between 4 and 55 miles per hour. With gasoline of 64 degrees Baumé gravity it showed 17.5 miles per gallon and a flexibility of between 3 and 61 miles per hour on high gear.

A Marmon then was run 200 miles on the new fuel and the valves showed no appreciable carbonization.

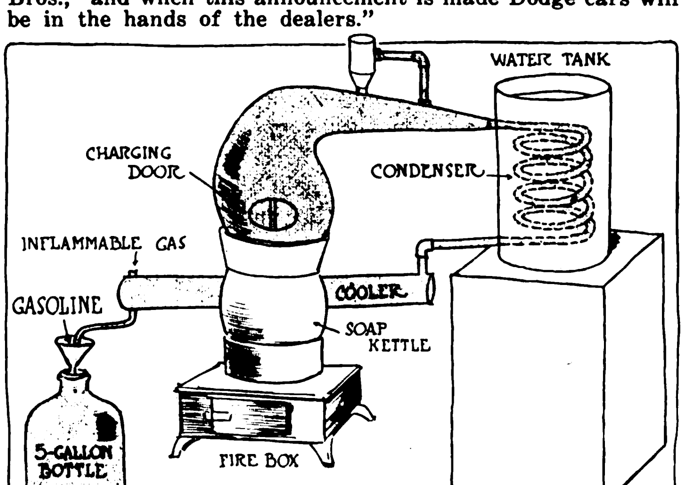
With the availability of this product, seemingly proven, the only doubtful point is the cost of manufacture. According to Andrews, it can be turned out at a cost of 2 cents a gallon. His word has to be taken on this point as he will not divulge the kind or nature of some of the chemicals employed, nor will he permit analysis of the product to be made. The chief ingredients are napthalene and water, neither of which is expensive. Andrews states that all of the materials may be obtained anywhere. As for fuel, the 5 gallons turned out yesterday required three lumps of soft coal, each no larger than a man's head, and four packing boxes split up for wood.

One of the features of the process is the fact that the gravity test of the product can be made whatever desired, simply by altering the proportions of the chemicals. That is, Andrews can obtain at will gasoline of any gravity between 50 and 90 degrees Baumé. At present he cannot hit the desired gravity test by a few degrees on account of the crude apparatus and seemingly haphazard way in which he guesses at the quantity of ingredients.

John Andrews is a Portuguese-American, born on the Maderia Islands, and living in McKeesport, Pa., and owing allegiance to King Manuel. Formerly a sailor and then a worker in the steel mills of Pittsburgh, where he selected the most dangerous work where he could get the highest pay wherewith to carry on his experiments. Recently, he received $350,000 from the United States government for the patent right to a new steel armor plate which he invented and with which the battleship Pennsylvania is being covered.

Dodge Bros. Incorporate for $5,000,000

DETROIT, MICH., July 8—*Special Telegram*—Dodge Bros. have incorporated, capital stock being $5,000,000. John F. Dodge is president and treasurer, Horace E. Dodge vice-president and general manager and Alfred L. McMeans secretary and office manager. The two brothers hold equal amount of stock, giving them full control, while McMeans holds balance. "No announcement about our new car will be made for at least 2 months," said G. C. Hubbs of Dodge Bros., "and when this announcement is made Dodge cars will be in the hands of the dealers."



Apparatus used to manufacture gasoline substitute

N. Y. Workmen's Compensation Law in Effect

Motor Car Manufacturers and Employers in Allied Industries Now Compelled to Indemnify Employees from Results of Accidents—Employer Is Compelled to Insure

NEW YORK CITY, July 1—The Workmen's Compensation Law, which went into effect in New York state today virtually supersedes the old Employer's Liability Law and, to a certain extent, the common law defense as well.

It applies to 47 groups of what are styled "hazardous" employments. These include more than 1,000 occupations. The various groups of so-called hazardous employments include practically all manufactures in the motor car and allied industries. They also include operators of garages and repair-shops, as well as motor car dealers.

The law states specifically that it shall apply to every hazardous employment where the workman is employed "for the pecuniary gain of the employer." This new law differs from the old common law in that it makes an employer responsible for injuries to his workmen whether or not the master is at fault; also, the old common law plea of contributory negligence on the part of a fellow workman is eliminated. In other words, it provides that every workman employed in any one of the so-called hazardous classes who is injured must receive a stated compensation.

EMPLOYEE MUST ACCEPT

The employer is compelled to provide this compensation; the employee cannot refuse to accept it. Agreements between the employer and the employee to waive any such compensation cannot be made, nor can the employer compel the workman to help pay premiums.

At the same time, the law takes away from workmen any and all right to sue under the common law for alleged damages. It also relieves the employer of the responsibility of such suits, but the employer must provide for compensation to his workmen; the law is virtually compulsory in this respect.

The entire burden falls upon the employer, and whereas under the old common law the workman was required to prove negligence on the part of the employer in order to recover for injuries received, the new law assumes—in the absence of substantial evidence to the contrary—that (1) The claim comes within the law; (2) That sufficient notice was given; (3) That the injury was not willfully intended; (4) That the injury did not result solely from intoxication while on duty.

If the employer fails to pay compensation within 10 days subsequent to the time when it is due he is subject to a suit by the state commission, which may declare the entire compensation recoverable in a lump sum with a penalty of 50 per cent. in addition. Such due payments constitute a liquidated claim for damages against the employer or the insurance carrier.

EMPLOYER MAY BE PENALIZED

If any employer fails to comply with the law by adequately providing for compensation to his workmen, the law states that "he shall be liable to a penalty for every day during which such failure continues of $1 for every employee, to be recovered by an action brought by the commission." The commission may, however, at its discretion, remit such penalty provided the employer secures proper compensation.

EMPLOYER COMPELLED TO INSURE

As already has been stated, the law is intended to insure compensation to those workmen whose labors come within the 47 groups that the commission has adjudged to be hazardous. Of these 47 groups there are probably seven that apply directly or indirectly to the motor car industry insofar as the dealer, garagemen and the repair-shop operator are concerned. These seven groups are as follows:

Group 4. The operation, including construction and repair, of machine shops, etc.

Group 16. Manufacture of furniture, upholstery, etc.

Group 21. Iron, steel or metal foundries, rolling mills, manufacture of castings, forgings, heavy engines, locomotives, shafting, wires, tubing, pipes, sheet metal.

Group 23. Manufacture of small castings or forgings, metal wares, instruments, water, gas or electric fixtures; light machines.

Group 24. Manufacture of traction engines, vehicles, automobiles, motor trucks, etc.

Group 25. Manufacture of explosives and dangerous chemicals, gasoline, petroleum, petroleum products.

Group 41. The operation, or otherwise than on tracks, on street highways or elsewhere, of cars, trucks, wagons or other vehicles, and rollers and engines propelled by steam, gas, gasoline, electricity, or mechanical means.

Group 41 covers very broadly the operation of motor cars and commercial vehicles, but in this respect it should be pointed out that the law states specifically that compensation shall be paid only to those who are employed for the pecuniary gain of the employer. This makes it plain that chauffeurs who drive private cars, for instance, do not come within the law inasmuch as they are not employed for the pecuniary gain of their employers.

The operation of repair-shops is quite clearly covered by Group 4 and this group may also be construed to cover the operation of garages.

The employer is compelled to provide compensation for those of his workmen whose occupations come within any of the 47 groups. He is compelled to give evidence that the compensation will be paid by insuring its payment. This may be had in one of four ways:

He may insure with the State Fund which is created under the new law for the purpose; with a mutual insurance company; with one of the many stock companies; or he may carry the insurance himself. It is not likely, however, that many employers will care to insure themselves; only men of unquestioned financial ability will be permitted to do so. Furthermore, "the commission may, in its discretion, require the deposit with the commission of securities of the amount prescribed in Section 13 of the insurance law in an amount to be determined by the commission to secure his liability to pay the compensation provided * * *" This security must remain until the liability for compensation ceases, which may be for 50 years or more.

COST OF METHODS EQUAL

There remain, therefore, but three ways in which the average employer can insure the payment of compensation. Each method has its advantages and its disadvantages. The cost of each method to the employer will be approximately the same. If the employer insures with the state fund, he is automatically relieved of all further liability for compensation. If, on the other hand, he insures with either a mutual company or a stock company, he is not relieved of all liability, for if the "insurance carrier," which means the company with which he insures, should fail, the employer would still be liable for compensation which might go on for an indefinite term of years—50 or more. As a measure of comfort, it may be added that such companies do not often fail. However, this slight hazard exists and it should not be overlooked, for only by insuring in the State Fund can the employer be relieved of all future liability.

If the employer insures with a stock company he will be required to pay a specified semi-annual premium based upon the amount of his payroll. This premium will never vary except as the payroll varies.

The premium which will be required by mutual companies, however, may vary. In other words, there may be assessments in addition to the premium. If, for instance, there should be a terrible catastrophe which would levy so heavily on the resources of the mutual company that an insufficient amount was available for the payment of all compensation, it would then be within the power—it would also be the duty—of the officers of the company to make an assessment upon each of the individual insurers to make up the difference.

STATE FUND HAS TWO ADVANTAGES

The advantages of insuring in the State Fund are claimed to be two in number. These are:

1. The employer who insures in this way extinguishes his liability to pay compensation, and
2. That the expense of managing the fund—not the claims for compensation, however—will be paid by the state for a time. [Two and one-half years.—Ed.]

Those who insure in the stock companies, on the other hand, will be liable for no extra assessments. Those who elect to insure their compensation in a mutual company virtually insure themselves; they become partners in a company which carries the insurance. The advantages of this form of insurance are claimed to be

1. Less expense, in that agents are eliminated;
2. Possibility of dividends in case the premiums should be slightly too high at first due to lack of experience;
3. Ability to insure against employers' liability under the common law and to reject undesirable risks.

In this respect it should be pointed out that whereas both mutual companies and stock companies have the privilege of rejecting undesirable risks in the same way that life insurance companies will refuse to write insurance on the life of a sick man; the State Fund has no such privilege; it must take all those who apply for insurance. It has the privilege of making its rates so high that they are prohibitive, however.

The cost of workmen's compensation insurance by two of these three methods is exactly the same. The rates quoted by the stock companies and those quoted by the mutual companies do not differ. The rates quoted by the State Fund, however, are exactly 8 per cent. less than those of the insurance companies.

In every case the premium rates are based upon the total payroll, the premiums applying to each $100 of wages or salaries. The rates charged by both mutual and stock companies for electric motor car dealers, either with or without garage, is 97 cents per $100 of payroll per year. For dealers in gasoline cars, either with or without a garage, the rate is $1.36. The rates charged by the State Fund on the same risks are 89 cents and $1.25, respectively.

These rates apply on the entire payroll, including such executive officers whose duties may expose them to the operative hazard of the business. The salaries of these officers is only included up to $1,500 a year, however.

The premium charged by the stock and mutual companies on machine shops which have a foundry is $2.07 per $100 of payroll per year. Where there is no foundry the premium is $1.36. The State Fund rates are $1.90 and $1.25, respectively.

The premium for a chauffeur driving a car for the pecuniary gain of his employer under the stock and mutual rates is $2.43 per $100 of payroll per year. The State Fund is 8 per cent. less. In neither case, however, can the total premium be less than $15 a year.

In connection with these rates, it should be remembered that under certain conditions reductions of as much as 40 per cent. may be made. Working together, the stock and mutual companies and the State Fund have created an inspection bureau. It will be one of the duties of this bureau to inspect the premises and to order reductions in rates in accordance with the condition of the premises. In other words, a machine-shop, for instance, which is in poor condition and where open gears, unprotected belting, unprotected stairways, etc., are rule rather than the exception, will pay the maximum rate; but where an earnest effort has been made to reduce the hazard under which the workmen operate, reduction in rates will be made accordingly.

What does the employee get under any of these forms of insurance? For the first two weeks subsequent to his injury he gets nothing, but the employer is required to furnish medical or surgical treatment for the first 60 days. During this period of the workman's disability the law states that the employer must furnish "such medical, surgical or other attendance or treatment, nurse and hospital service, medicine, crutches and apparatus as may be required or may be requested by the employee during 60 days after the injury."

The compensation due the workman is based upon his average weekly wage. This is obtained by multiplying his daily wage by 300 and dividing the product by 52. For total permanent disability, the workman will receive 66 2/3 per cent. of his average weekly wage during the continuance of his disability.

Suppose, for instance, the case of a man 21 years old, earning $22.50 a week. If he is permanently totally disabled he will receive $15 a week as long as he lives; there is no limit to the amount of payment. If he lives 40 years, he receives $31,200; if he lives 50 years, he receives $39,000.

For total temporary disability, this same workman will receive $15 a week during the continuance of his disability until he has received a total of $3,500; for partial temporary disability he will receive $15 a week for varying lengths of time, depending upon the extent of his injury, the schedule being as follows:

Loss of	Weeks	Payment
Thumb	60	$900
First finger	46	690
Second finger	30	450
Third finger	25	375
Fourth finger	15	225
Great toe	38	570
Any other toe	16	240

(Note.—The minimum limit of weekly compensation is $5. In other words, if the workman is receiving but $5 a week the compensation will amount to his regular wage; the maximum limit of weekly compensation is $15 a week.)

Loss of	Weeks	Total Payment
Hand	244	$3,660
Arm	312	4,680
Foot	205	2,075
Leg	288	4,320
Eye	128	1,920

(Note.—The minimum weekly compensation is $5 and the maximum in this case is $20 per week.)

In all other cases the rate of compensation will be 66 2/3 per cent. of the average weekly loss of wages payable during the continuance. In such cases there is no limit to the amount which may be paid.

Driggs-Seabury Gets U. S. Truck Order

NEW YORK CITY, July 6.—The Driggs-Seabury Ordnance Corp., Sharon, Pa., maker of the Vulcan truck, has entered into contract with the U. S. Government to supply 2 and 3-ton trucks during the fiscal year, starting July 1. The estimated number of trucks to be required is between 100 and 120.

3,732,585 Sq. Ft. in Ford Plant After Expansion of 10 Years

In Decade Buildings Now Under Way Will Occupy 85 Acres and House 40,000 Workers

DETROIT, MICH., July 6—Within the next 5 years the Ford Motor Company's plant at Highland Park, Detroit, is to be gradually enlarged so that in 1919 it will have a total floor space of 3,732,585 square feet or cover a piece of ground of 85 acres. At present the plant occupies 45 acres, has room to employ 20,000 men but when the buildings that have been planned are completed the Ford organization will be able to give employment to 40,000 men.

Two buildings 900 feet long, 60 feet wide and 6 stories high costing about $500,000 each were started last year and are now almost completed. Five buildings entirely similar to these, are to be erected within the next 5 years. Like the two nearly finished they will be of concrete with steel columns and rafters supporting the upper floors. There will be a craneway between each building, into which the trains of the Terminal railway will be run. Each of the 6 craneways will be 40 feet wide.

On the lower floors of the buildings, cars and material will be stored, while on the upper floors parts will be made. All these structures will have glass fronts from the third to the sixth floor.

A new power plant is being erected and it will be, according to the Ford company, one of the largest in the world and will have the largest gasoline engine (of 30,000 horsepower) thus far constructed in the world. The power plant will be 240 feet long, 150 feet wide and 85 feet high, and will cost about $1,500,000. When the plant and the other buildings have been completed it will represent an outlay of about $5,000,000.

Brown-Lipe-Chapin Get New Differential

NEW YORK CITY, July 6—The Brown-Lipe-Chapin Co., Syracuse, N. Y., has entered into an agreement with the M. & S. Gear Co., Kansas City, Mo., whereby the Syracuse company secure American manufacturing rights to the M. & S. spiral gear differential. It is the company's intention to manufacture the device in quantities for motor car and axle makers.

The device was invented by William Muehl who constitutes the M. in the M. & S. company. The S. is L. H. Scurlock. The differential differs from the ordinary type in that power is transmitted from the master gear to the axle shaft through spiral gears. Spiral gears are anchored in a housing which is attached to the master gear. The axes of the spiral gears constitute arcs of the circumference of rotation of the housing and they engage a corresponding gear on the shaft.

The advantage claimed for this construction is that tractor effort is equalized. The car wheel which has the greater traction received the greater power through the differential. In case one wheel is in sand or mud and does not pull and the other wheel is on solid ground this wheel will receive sufficient power to pull the car. Dangers of skidding on slippery pavements are said to be reduced by this type of construction.

Metropolitan S. A. E. Discusses Headlights

(*Continued from page 91*)

to quote Dr. Steinmetz, saying that the light that entered the eye was transformed into heat and absorbed by the body. When the glare is marked this heat is sufficient to cause inflammation. The No-Glare glass is designed to cut out the blue, violet and ultra-violet rays and in this way to eliminate the harmful glare.

The J-M frosted glass lens secures its non-blinding qualities, according to Otto Luyties, by the use of a concave, frosted glass lens at the bottom of which there is a slot of white glass which permits the rays to be thrown on the road in front of the car. These rays illuminate the road far enough ahead to answer the requirements of ordinary driving and the non-glaring qualities of the frosted glass remove the objections in city work.

The discussion which followed was opened by A. L. McMurtry, consulting engineer, of South Beach, Conn. He pointed out the requirements of the non-glaring headlight and stated that there seemed to be several methods of approaching the problem. This discussion was a round-table affair and very largely concentrated itself on how glare could be accurately defined and its causes. J. G. Middleton, maker of the Glare Breaker, stated that he believed that the definition of glare would have to be left to the county constable and that he would be the one who decided whether or not the headlight was glaring. For this reason Mr. Middleton stated that it was his belief that the subject should be treated in a direct, practical manner, rather than in a theoretical way. Leonard Kebler stated that it was his belief that the headlights should be deflected toward the ground instead of straight ahead.

150,000 More Cars in 1914 Than 1913

Registrations of 1,203,770 Cars in 33 States for 6 Months Proves Times Are Sound

ALBANY, N. Y., July 3—"Despite the widespread talk of hard times and business depression which has characterized the last six months," says Mitchell May, Secretary of State, "the motor car industry does not appear to have been but slightly affected, if a comparison of the registration statistics reported by the thirty-three states below listed is made.

"According to the most accurate figures obtained by direct communication with the licensing authorities in these commonwealths, during the first half of the present year the number of automobiles registered increased from 1,065,000, recorded for the entire period of 1913, to 1,203,770, the total reported from January to June 25th, of the present year, a gain of nearly 150,000 cars; motorists paying $8,386,108.69 in license fees since the first of the year.

"A substantial increase is noted in twenty-six states, New York still leading far in advance with Illinois retaining second place, while California, owing to her new law requiring re-registration of all cars, jumps from seventh to third place. Ohio drops back into fourth, followed by Pennsylvania, where the figures reach nearly the hundred thousand mark."

State	1914 Jan. to June 25	1913 Jan. to Dec.	1911 Jan. to Dec.
New York	147,186	132,579	81,655
Illinois	110,000	95,592	42,000
*California	104,830	60,000	14,566

Market Reports for the Week

MARKET reports for this week remained generally steady. With the exception of tin and Bessemer and open-hearth steels, prices remained at last week's prices. There were a few small changes, but of no consequence. On Thursday, both Bessemer and open-hearth steels dropped $.50 per ton. Tin rose $.87 per 100 pounds with a reaction at the end of the week, followed by a $.25 reduction in price. There were freer offerings of nearby positions in this city at concessions and there was a small demand from the consumers. A reaction in copper was followed by slightly higher prices. Lead was dull but steady.

$1,000,000 Indestructible Tire Co. Chartered

WILMINGTON, DEL., July 6—The Indestructible Tire Co. of the United States has been incorporated under the laws of Delaware, with a capital of $1,000,000, to purchase, lease, own, hold and deal in and with tires made from rubber, metal, cloth or other fabrics, for all kinds of vehicles. The incorporators are John McLarin, F. B. Knowleton and S. V. Dowling, all of New York City.

CLEVELAND, O., July 8—The Garford Co., Elyria, has passed the quarterly dividend of 1¾ per cent. on the preferred stock. There is outstanding $500,000 of the issue. The brokers are attempting to arrange a plan whereby an exchange of Garford preferred for Willys-Overland Co. stock can be made.

Stewart-Warner Earns $400,000 on Common Stock

NEW YORK CITY, July 7—The earnings of the Stewart-Warner Speedometer Co. in the quarter ended June 30 last were more than $400,000 on the common stock and for the 6 months period ended on the same date total earnings applicable to dividends were around $600,000. This showing is equivalent to the full year's 7 per cent. dividend on the preferred and 6 per cent. for 6 months on the common.

DETROIT, MICH., June 7—A dividend of 5 per cent. was ordered paid by Referee in Bankruptcy, L. F. Joslyn yesterday to 753 creditors of the R. C. H. corp., including the agents who had made deposits.

New Stock Sold by Miller Rubber Co.

AKRON, O., July 4—The Miller Rubber Co. has succeeded in reducing and rearranging its current debt by retiring of its old preferred stock and reissuing therefor new first preferred shares to the amount of $500,000.

A Cleveland banking house, Borton & Borton, has purchased $400,000 of the stock, which is being offered to the public at 98 plus accrued dividends. $1,000,000 in common stock is outstanding out of a total authorized $1,500,000.

The net earnings for the last fiscal year were five times the preferred dividend requirements on the new issue. The company's sales have increased from $289,840 in 1910 to $1,658,618 in the 11 months ended with May, 1914.

Gasoline Prices Down Throughout Country

NEW YORK CITY, July 6.—Price cutting on gasoline has not only hit this section of the country, but also out West. In Portland, Ore., the automobilists are generally taking advantage of a little gasoline war that has sprung up in that city. The big companies are now selling wholesale at 15½ cents in 50-gallon lots. To big commercial houses who use gasoline in large quantities this price is reduced another half cent, while to garage men and retail sellers of gasoline who use still larger quantities the price is reduced still another half cent.

In Hartford, Conn., all the garages have dropped to 15 cents a gallon in an effort to break up the cut-rate element. Practically every dealer asserts that because of the cut rates of the independent concerns business has fallen away. With the drop by the dealers to 15 cents they assert that business is returning. It is asserted that the price will drop still lower during the next two or three weeks.

The State Corporation Commission in Oklahoma has issued orders fixing the prices on gasoline throughout the State. The retail price is not to exceed 15 cents a gallon except in towns where delivery has to be made from other towns by wagons. The wholesale price is fixed at 12 cents and 13 cents a gallon, the variation being due to the difference in freight rates. In cities and towns close to stations and centers of distribution, the retail price is not to be over 14 cents. The order takes effect at once.

Peerless Conserves Resources for New Plans

CLEVELAND, O., July 6.—The Peerless Motor Car Co. has deferred the payment on the 7 per cent. cumulative preferred stock, because the directors have decided to conserve the resources in view of the fact that the company will soon put a popular-priced car on the market in connection with its present higher-priced line of automobiles.

Walpole Receivers Report a Profit

BOSTON, MASS., July 6—The receivers of the Walpole Tire & Rubber Co., have filed their second report, showing a net profit of $83,801.03 for the 5 months ending May 31. The total earnings amounted to $112,359.64 on sales aggregating $708,486.90.

The receivers report total assets of $406,442.94 for the Walpole Rubber Co., Ltd., of Granby, Que., and assets of $342,074.69 for the Walpole Shoe Supply Co. The latter has a surplus of $34,688.44, and the former a surplus of $27,323.05.

Fire Destroys One of Havers Factories

DETROIT, MICH., July 8—*Special Telegram*—The main plant of the Havers Motor Car Co. at Port Huron, Mich., was destroyed by fire last night. Several finished cars, chassis, bodies and parts were consumed, the damage being estimated at $60,000. The origin of the fire is unknown as yet but thought to have been in the assembly room.

June Sales of Packard Trucks, $825,394

DETROIT, MICH., July 2—The Packard Motor Car Co. states that the sales of Packard trucks to users during the month of June totaled $825,394. This is exclusive of bodies. Not only is this total remarkable in the face of prevalent business conditions but it culminates 4 months of record breaking truck sales.

In March the Packard company sold more than $750,000 worth of trucks. In April the business total was 60 per cent. greater than in April, 1913, while the May total was also 60 per cent. greater than in the corresponding month last year.

The June sales exceed those of June, 1913, by $256,994, an increase of nearly 50 per cent.

The largest individual order received during June was one for twelve Packard 3-ton trucks from the Marshall Field Company, Chicago.

Automobile Securities Quotations

NEW YORK CITY, July 8—Continued inactivity marked the automobile and allied securities during the past week. Most of the stocks made a slightly better showing than a week ago today, there being many slight gains noticeable. The number of stocks showing losses is less this week and a slightly optimistic tone is to be noticed throughout. Brokers state that they expect more pronounced gains the coming week.

The only losses of any consequence during the past week were one of five points by Studebaker preferred, 1½ points by Texas Co., 1 by Vacuum Oil and also by New Departure common and preferred. Willys-Overland continues very strong in both common and preferred showing a gain of 7 points on the common and 2 on the preferred. The full quotations for the week follow:

Austin Sues Cadillac Co. on Two-Speed Axle Patent

Damages and Restraining Order Asked—Defense Is That Superior Prior Patent Was Purchased —Austin and Cadillac Axles Differ

GRAND RAPIDS, MICH., July 7—The two-speed rear axle used and exploited by the Cadillac Motor Car Co., Detroit, Mich., is alleged to be an infringement in an action filed in the United States District Court here by W. S. Austin, head of the Austin Automobile Company, Grand Rapids.

Austin, suing on patent No. 1,091,618 issued to him on March 31, 1914, asks for an injunction against the Cadillac company and damages for the use of the axle in 15,000 cars.

In defense the Cadillac company explains that Austin endeavored to interest it in his axle in the Spring of 1913 but rejected the invention because it believed the clutch on the rear axle and clutch on the drive shaft was an unsatisfactory arrangement.

A device incorporating one clutch, located on the drive shaft, patented in 1902 by Willis G. Caffrey, was preferred, explains the Cadillac Co., and this patent was purchased.

In a statement Austin says:

"Cadillac became interested in my two-speed axle when it was exhibited at the Chicago automobile show in February, 1913. The company wired me to send them an axle by express and wrote requesting complete drawings showing different constructions that would be suitable for the Cadillac car. I sent them an axle and drawings, and from my correspondence and interviews with them felt assured they intended to adopt my axle and pay a suitable royalty for the use of it.

"As my patent claims were still pending, I could not give them definite reply to their request for full information as to the claims that would be allowed. They finally dropped their correspondence with me and put out a two-speed axle under their own name."

"Our patent attorneys," said Henry M. Leland, of the Cadillac company, "inform us that we do not infringe the Austin patents in any respect. We considered the two-speed axle proposition five years ago and from then until the time we adopted it we experimented with various designs."

Court Advises Separate Sale for Pope Plants

HARTFORD, CONN., July 8—Judge William L. Bennett, of the Superior Court, to-day dismissed the petition of the Boston creditors of the Pope Mfg. Co., which was to the effect that the entire assets of the Pope Co. be sold at auction in Massachusetts by the receiver, Col. Geo. Pope.

Judge Bennet was led in this action of dismissal by the belief that if the bicycle plant at Westfield, Mass., and the automobile plant in this city should be sold separately, and that it will be for the benefit of the preferred stock holders. The creditors will undoubtedly be paid in full and if a good sale is made there may be something for the stockholders. This belief is based on the fact that the Westfield, Mass., plant where bicycles are manufactured has always been a highly satisfactory and successful plant, whereas the automobile plant at Hartford has not been profitable.

Judge Bennett believes that the offer of $1,800,000 made by a Boston syndicate for the entire assets is like sacrificing the property, and it was to avoid this that he dismissed the petition and has advised Receiver Col. Geo. Pope to get an order to sell the property separately. The memorandum from Judge Bennett says:

It appears from the evidence that the property of the defendant corporation in Connecticut consists of a large manufactory and plant for the making, selling and repairing of automobiles and motor trucks, and that the corporation has in the state of Massachusetts a manufactory and plant for the construction, selling and repairing of bicycles and motorcycles.

The business carried on in the establishment in Massachusetts is entirely separate and distinct from that carried on in the Connecticut factories. The Massachusetts business has prospered and has been and is exceedingly profitable. The Connecticut business, on the contrary, has failed to earn profits. Both of these concerns have been carried on in the name of the Pope company.

Since the two establishments of the defendant are in fact separate establishments, each engaged in carrying on its own business, the goodwill alone being the connection between them, if this was all the petitioners had to offer as a reason for a sale at auction of both establishments together as a whole, I should not consider such sale advisable. Each manufacturing plant is of great value, and while customers might be found desirous of purchasing a bicycle business, and others willing to bid for the automobile plant, it would seem more difficult to find one purchaser for both, and the result might easily be that one or the other might be sold for less than its real value.

The petitioners, however, say they have obtained a purchaser who will bid at the auction sale, if such sale is ordered, $1,800,000 for the whole property and assets; that he will bid no greater sum than this, and that he will bid for the whole of the property or for none.

No Other Bidder?

Inasmuch as no one has suggested to the court that any one else has any intention of bidding at the sale, and as it is extremely improbable that any such person will appear, this is in effect a proposition to the two courts having the property and assets of the Pope Manufacturing company in control, to permit a sale for $1,800,000 and this court must endeavor to ascertain whether the sum offered is a fair and adequate price.

The evidence shows that the Massachusetts plant is worth, and ought to bring, $1,250,000, and having heard the evidence I am of the opinion that the Connecticut property is worth and may fairly be expected to sell for more than $550,000. If this petition should be granted it would seem that the Connecticut property would be sacrificed in order to obtain the Massachusetts property.

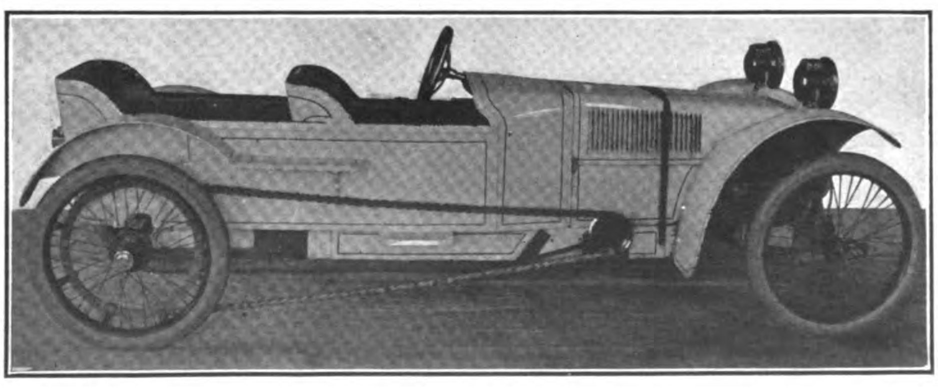
The receiver is of the opinion that however that property is sold, the creditors may reasonably expect to be paid in full, and there is a chance, if the properties are sold separately, to obtain something for the preferred stockholders. This is my own opinion.

The receiver is, however, advised to make application to the court, or if the court is not in session, to a judge of the superior court sitting in chambers, for an order for the sale of the property and assets of the defendant corporation.

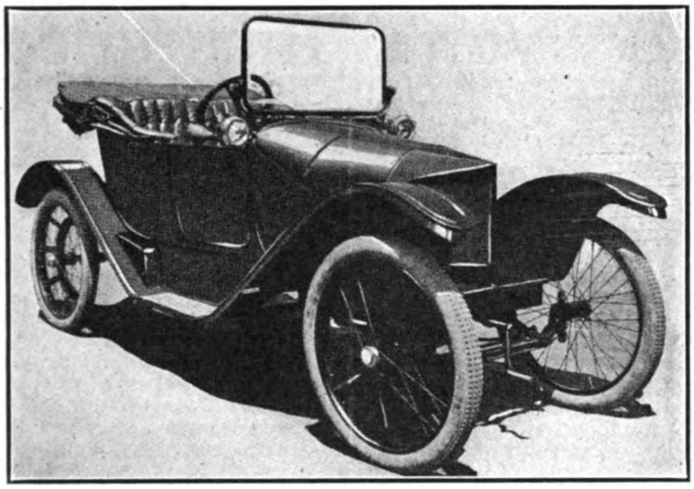
Perry Chain Co., Infringing, Must Quit

CINCINNATI, O., July 6—The Perry Chain Co., Lansing, Mich., which began manufacturing tire chains in 1909 and which since that date has been prosecuted in the courts by the Weed Chain Tire Grip Co., was ordered to cease operations last week by the United States Circuit Court of Appeals in Cincinnati. This court sustained the decision of the United States District Court for the Eastern District of Michigan, which held the Parsons patent No. 723,299 infringed in an action which was terminated last Fall.

The Perry company originally provided its cross chains with tension springs for the professed purpose of causing the grip to fit snugly and not creep. In 1911 this type of chain was substantially abandoned and was followed by the "Weeder." In 1912 the "Weeder" grip was enjoined, whereupon the Perry company began to market the Peerless and Emergency grips, both of the "anchored" type. The Perry company contended that the Parsons device was anticipated by the armor plate guard used on the old style rubber tires of the Thomson traction engine about 1870. This defense was not accepted by the court, which held that Parsons was originally the inventor of the anti-skid chain.



Burrows two-cylinder tandem cyclecar which lists at $375



Koppin light car with V-radiator and streamline body

Following the decision of the lower court a special master rendered an accounting and awarded the Weed company $17,-498.50 damages. A motion for confirmation of the master's report was made and later withdrawn in the appellate court but will be made again.

The Weed company also recently secured a preliminary injunction against the Woolston Mfg. Co., Trenton, N. J., which has been making tire chains and parts.

Koppin Light Car To Sell at $385

DETROIT, MICH., July 5.—The Koppin light car has made its appearance in Detroit. It is built by the Koppin Motor Company, Fenton, Mich., of which H. S. Koppin, one of the best known real estate men in Michigan, is the president. The Koppin company occupies the plant of the old Fenton Cyclecar Company, which has been reorganized after the death of several of its stockholders.

For the present there will be only one model Koppin chassis with one standard body. The motor is an air-cooled, two-cylinder De Luxe of the V type, 3½ inches bore and 3⅝ inches stroke, developing about 13 horsepower. Transmission is of the friction type mounted on large ball bearings.

The standard equipment of the Koppin, which sells at $385, consists of top, side curtains, special design windshield, electric side and tail lights with 6 amp. 60 hr. 21 plate storage battery controlled by dash switch, horn, repair kit, pump and tools.

The offices of the Koppin company are presently at 305 Breitmeyer building, Detroit.

Longuemare To Push Imported Carburetors

NEW YORK CITY, July 8—Following the litigation between the Stromberg Motor Devices Co. and the Longuemare Carburetor Co. in the United States District Court in New York City, the Longuemare company is preparing to push the importation and sale of its foreign made carbureters. A preliminary injunction was issued by Judge Hand, but it affects only the making of carbureters in America. The Longuemare company is permitted to import and sell under a $10,000 bond which it will file before July 22. "The Longuemare Carburetor Co.," states Ludwig Arnson, one of the proprietors, "is convinced it does not infringe the Richard and Ahara patents and, believing that this will ultimately be demonstrated, is preparing to push the imported Longuemares."

Freight Must Be Paid for Blocking, Decides Commission

Interstate Board Disallows Dunnage in Protest of National Automobile Chamber Against S. W. Railroads

NEW YORK, July 5—The dunnage allowances which have been conceded by practically all of the railroads in the United States have been disapproved by the Interstate Commerce Commission and after July 15 all blocking for motor cars shipped in freight cars will have to be paid for at the same rate as is charged for the shipment of the cars which are blocked.

The decision affirms a ruling of the Southwest Tariff Committee which represents practically all of the railroads in the Southwest. The roads originally allowed 500 pounds of blocking to be carried free of freight charges, provided the weight of the carload was above the minimum. This dunnage allowance was made on the theory that it induced shippers to use care in blocking up their cars and. therefore, was of benefit to both the railroad and the manufacturer.

The Southwestern roads cancelled their dunnage allowance several months ago and the National Automobile Chamber of Commerce protested to the Interstate Commerce Commission against the cancellation. The commission denies the chambers petition on the ground that dunnage is in the same class as crating or boxes in which other wares are shipped and that regardless of the ultimate benefit it should be excepted. Pending the decision the cancellation had been suspended.

A Truck Convention in October

NEW YORK, July 2.—Plans are being perfected by the National Automobile Chamber of Commerce for a convention of commercial vehicle interests to be held some time in October to further advance the excellent work that has been done during the past two years.

Burrows Cyclecar Lists at $375

NEW YORK CITY, July 6—With its long, narrow hood, high cowl and tandem seating, the $375-Burrows cyclecar has a very speedy appearance. It is equipped with a 13-horsepower, two-cylinder, air-cooled motor which has its cylinders set at an angle of 45 degrees. The crankshaft is carried on imported annular ball bearings. Ignition is supplied by an Atwater Kent Unisparker and carburetion is furnished by a Schebler, automatic type.

Speed changes are provided by a friction transmission located forward of the driver and it gives four speeds forward and reverse. The jackshaft is a special, flexible design mounted on annular ball bearings. Final drive is by double V-belts to large pulleys on the rear wheels. An adjustment for the stretching of the belts is provided.

Selected ash, having a cross-section 1 by 5 inches, is the material from which the frame is made, it being reinforced by steel flitch plates and cross members. The car is suspended upon quarter-elliptic vanadium springs, front and rear.

Twenty-eight by 3-inch Goodyear non-skid tires, mounted on wire wheels, are employed. The steering wheel is 14 inches in diameter and the gear is provided with an adjustment.

The equipment includes J.-M. Mobilite electric headlights, tail light, horn, and full tool equipment. Its weight is 700 pounds.

This cyclecar is manufactured by the Burrows Cyclecar Co., Ripley, N. Y.

Garagemen and Dealers Win Separator Fight

NEW YORK CITY, July 8—The garagemen and dealers of New York City have won their fight against the gasoline separator ordinance. The board of aldermen at its last meeting of the summer held yesterday, July 7, acceded to the request of four garagemen and dealers' associations in Greater New York and passed Alderman Squire's ordinance, which repeals the statute placed upon the books 4 years ago requiring the installation of separators in garages. The final vote stood 57 for Alderman Squire's ordinance and 1 against it. This ends 4 years of prosecution by the city and insistence by the municipal authorities that garages install, at high expense, a device which when working at its best would not prevent gasoline and oil getting into the sewers, and in a majority of instances would not operate at all.

At a hearing before the welfare committee, prior to the hearing of the board of aldermen, Attorney Charles Thaddeus Terry, for the garagemen, had classed the prosecution by the city as tyranny and the welfare committee was won over to the side of the automobile men, laboring in behalf of the repeal of the old ordinance.

Underwriters Not To Write Insurance

Business Is To Be Centralized—Data on Both Chauffeurs and Owners To Be Compiled—Plan To Recover Stolen Cars

NEW YORK CITY, July 1—The motor car insurance business of the United States is to be centralized and systematized insofar as the adjustment of losses is concerned; data as to every chauffeur and as to car owners applying for insurance is to be compiled and classified; recovery of stolen cars is to be made the work of a nation-wide bureau. These are the objects of the Manufacturers and Dealers Motor Underwriters, Inc., in a proposed plan which has been adopted, following alterations in its policy as announced in THE AUTOMOBILE for June 18, page 1286.

It was originally proposed that the company represent two of the large insurance companies and make motor car dealers its agents, permitting the dealer to sell insurance and providing that repairs covered by insurance be made by the dealer in the car damaged, regardless of what city the dealer be located in.

Under the new plan the company will write no insurance at all, will appoint no agents but transforms itself into a service bureau. A rule will forbid anyone connected with the company from assisting in the securing or placing of any insurance and it will act impartially toward all companies.

The Automobile Service and Inspection Bureau has been formed theoretically as a department of the business but in reality all the company's business will be transacted by this bureau. In fact, the company name may later be relegated to the background and the name of the bureau brought forward as the name of the business.

It has been proposed that this service or bureau be supported, by the various companies making use of it, through a subscription based on a percentage of their premium income in motor car insurance. The service rendered to a company with $1,000,000 premium income would be twice as great and twice as expensive as the service rendered a company with but $500,000 premium income.

In brief, it is the purpose of the bureau to reduce the loss ratio of the insurance companies to a minimum, and it is believed that, with the co-operation of the insurance companies and the motor car dealers and manufacturers, much can be accomplished in this direction.

Correspondents in Every City

The bureau will have correspondents in every city of any size in the United States. In the majority of instances this correspondent will be the paid secretary of the local motor car dealers' association, or of the local automobile club. Through a connection with the motor car trade which has already been established, the bureau will be in touch with every dealer in the United States. This connection, together with the local correspondents, forms the basis of the field organization. The bureau will, of course, have branch offices in the larger cities, such as Boston, Philadelphia, Chicago, Detroit, San Francisco, and other important centers.

The companies subscribing to the bureau will have the privilege of submitting to it, each day, a list of applications for insurance received by them on second-hand, old, and mortgaged cars whenever there is any question concerning the underwriting value of the car. In submitting this data to the bureau it will only be necesary for the insurance company to give the name of the assured, his address, the name of the car, and the model.

The bureau will immediately communicate with its local correspondent and obtain a report on the assured as to all matters affecting the moral hazard of the risk. This report will be forwarded to the company, together with an estimate of the insurable value of the car involved. Estimates of the insurable value of cars will be made by skilled and experienced men who can quickly tell what the probable value of the car is from its description.

As the bureau will have no knowledge of the amount of insurance applied for, a fair and unprejudiced report can be made on any particular risk either as to the moral hazard involved or the value of the car. Such a report on risks of this kind will enable the insurance company to decide whether or not they should write the risk for the amount applied for.

By moral hazard is meant the risk attaching to the owner or the chauffeur; that is, whether they are reliable men, whether the business of the owner makes the risk greater or whether information secured about either owner or driver causes apprehension on the part of the insurance company. All these will be passed upon by the bureau.

It is the purpose of the bureau to establish a card index or registration of chauffeurs throughout the United States setting forth the record of each individual chauffeur. This, at first glance, may seem like a tremendous task, but, through the connection already established with the trade and various motor car clubs, is believed that it will be simply a matter of clerical work to obtain the names of all the better class of chauffeurs in the United States, and this index or registration can very rapidly be built up to a high state of efficiency.

The companies may submit to the bureau a list of risks with the names of the chauffeurs used, and the bureau will immediately report to the company on all those chauffeurs of whom it has record. If there be in the list the name of any chauffeur not upon the bureau's records, the local correspondent will be immediately communicated with and this record obtained.

Stolen Cars To Be Traced

An important feature of the work will be the tracing and recovery of stolen cars. Having, as it will, a correspondent in every city, and being in close touch, either directly or through these local correspondents, with all dealers and garages, the bureau can spread a net-work over the entire United States which will make it extremely difficult for the motor car thief to get very far.

It is proposed that whenever a car is stolen the insurance company or its agent immediately notify the bureau through its nearest correspondent. It will be the duty of that correspondent immediately to notify every dealer, garage, and police department, within a sufficient radius to locate the car quickly. With a system of this kind it would be impossible for the car thief to enter any city or any garage or local dealer's place of business. He would be picked up within a few hours after the bureau or its local correspondent has received notification of the theft.

In the recovery of a stolen car the company would necessarily pay all expenses incurred in securing its return after it has been located by the bureau.

As soon as the car is located, the company will be notified and may itself take such action as may be necessary to obtain the car; or its return will be undertaken by the bureau at the company's request.

Insurance companies, as a rule, have objected to being bound by an agreement to return a damaged car to the manufacturer or dealer, and have insisted that it is their right to get a number of bids on any repair job and to give it to the lowest bidder. This has often resulted in dissatisfaction on the part of the assured, even though the repairman be extremely efficient.

In this connection the bureau can render a great service. It can make it possible for all the subscribing insurance companies to make adjustment in the event of partial loss in any place in the United States, by having the car repaired by the nearest dealer in that make of car if he is equipped to handle the repairs and, at the same time, be assured that the repair bill will be absolutely legitimate.

The bureau will have intimate connection with the entire motor car trade and through this connection will be able to control all adjustments made in this way. If, for example, a car is damaged in a city like Syracuse the bureau will be in a position to recommend to the insurance company the best place to have the car repaired. In most instances, this will be the dealer who sold the car.

By having a connection with the manufacturer of that car, the bureau will be able to assure the insurance company that it will receive fair treatment from the dealer in that particular town. If it does not, the bureau will take the matter up with the manufacturer. Wherever any dealer persists in making excessive or unreasonable charges the bureau will refuse to recommend that dealer for repair work and his manufacturer will be notified immediately.

Furthermore, the bureau will have in its employ a number of experienced motor car men who will be able to judge any item of time or repair parts. It will be extremely difficult for an unscrupulous dealer to overcharge or conspire with his customer to do work on the car not made necessary by the accident.

The service, of course, does not contemplate supplanting the adjusters of the insurance companies. The object is to provide a service which will assist in adjustments and make it possible for the insurance companies to have their repair work done by the manufacturer or dealer at a less expense and in a better manner than elsewhere.

There are a number of additional features, valuable to underwriters, contemplated as part of the bureau which will be established as rapidly as possible. A careful record of all losses will be kept where there is any question concerning the claim. This will enable the bureau to furnish the insurance companies with data of value concerning various classes of risks.

A careful study will be made of traffic conditions throughout the United States and of all circumstances surrounding every possible kind of motor car hazard, all of which will be useful in insurance work. The bureau will co-operate with local authorites throughout the United States in an effort to eliminate from the public highway, as far as possible, the reckless driver. In all cases of reckless driving coming to its attention, the bureau will insist that the highway commissioner of the state involved revoke the driver's license.

Transcontinental Tour Is Abandoned

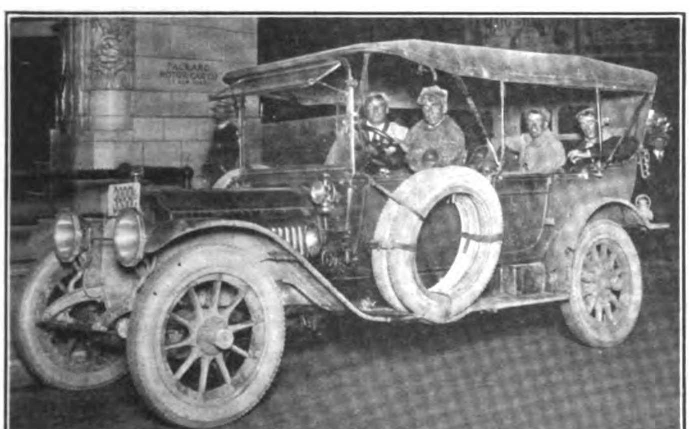
MAPLEWOOD, N. H., July 7—At the midsummer meeting of the American Automobile Assn. now in session it has been decided to abandon the transcontinental tour which was to have terminated within the fair grounds of the Panama-Pacific exposition to be opened in San Francisco in January. In place of the tour the energies of the association will be devoted to routing the principal national highways and to the establishment of a rendezvous for members in San Francisco, Los Angeles and Seattle and to aid in every way possible members who are making the long trip across the continent.

Resolutions were also adopted in favor of a universal wheel tax, against unjust discrimination against automobilists and in favor of the regulation of individuals in their use of the highways. Governor Welker, of New Hampshire, who welcomed the members of the association, said that three trunk lines have now been constructed from the northern end of New Hampshire to the state line of Massachusetts on a state air basis. Commenting on federal aid ex-Congressman S. L. Powers stated that the national government would probably require the states to raise an amount at least equivalent to that appropriated by the nation.

General Motors Business Shows Increase

NEW YORK CITY, July 8—A statement just issued by the General Motors Truck Co. shows a substantial growth in the company's business for the first 6 months of this year. June business exceeded that of June, 1913, by 17 per cent., while the increase for May was 36 per cent. and for April, 20 per cent.

The sales last month exceeded those of May, 1914, by 9 per cent., and May sales were 17 per cent. ahead of those for April of this year.



1913 Packard 48 driven by E. C. Patterson from Chicago to New York in 41 hours 37 minutes

Lincoln Highway Saxon Completes 3,389-Mile Run

Made Transcontinental Trip on Schedule—Averages 30 Miles Per Gallon of Fuel

DETROIT, MICH., July 7—*Special Telegram*—Arrival in San Francisco ended the 3,389-mile trip of the Lincoln Highway Saxon across the continent from New York. According to a dispatch the car reached destination July 4 on schedule, arriving in excellent mechanical condition and averaging 30 miles per gallon of gasoline and 150 miles per quart of oil on its long journey. This Saxon is the first automobile to traverse the Lincoln way on a continuous run, and the first car of its size and price ever to cross continent.

True Far-West hospitality marked the reception given car and drivers, M. A. Croker and Fred Wilkins, at the completion of the run. An escort party went 25 miles out of San Francisco and piloted the coast-to-coast Saxon into the city. Enthusiasm among the crowds that awaited the arrival of the car was at high pitch and many cheers went up when, ocean-to-ocean traveler paraded streets of city.

Upon reaching San Francisco Pilot Croker drove the front wheels of the car into the Pacific ocean so as to make trip literally ocean-to-ocean run. He also emptied water carried from the Atlantic into the Pacific ocean.

The finish of the journey proved spectacular, the Saxon showing a remarkable burst of speed in covering the last 290 miles from Reno to San Francisco in 2 days. For part of the way, the road leads down hill across California, but the route in the Lake Tahoe district provides one of the severest tests in the way of mountain climbing on the whole Lincoln Highway.

The run of 186 miles in 1 day between Kimball, Neb., and Denver, Col., was the record mileage made by the coast-to-coast car. Runs of 170 miles and more were frequent west of the Mississippi, despite the fact that for the most part the road is almost a uphill climb.

Over all kinds of roads and hills and through all kinds of weather, this car maintained the schedule mapped out at the start of the run. It crossed long grades of the Alleghanies between New York and Canton, O., without requiring addition of water to radiator supply.

Before undertaking this trip, the same car made a run of 135 miles a day for 30 consecutive days in Detroit. The 4,050 miles covered on that occasion, coupled with distance of 3,389 miles across the Lincoln Highway, brought total for 60 days of travel up to 7,439 miles, or equivalent of 2 years' service in the hands of the average owner.

Chicago To New York in 41 Hours

NEW YORK CITY, July 8—E. C. Patterson, the Chicago motor sportsman, reached this city last night in his non-motor-stop run from Chicago, covering the distance in 41 hours and 37 minutes. With a party of three in a 1913 Packard 48, he left Chicago at 3:58 a. m., Monday, July 6, and reached this city at 10:25 last night. Mr. Patterson with an assistant drove the car in 4-hour relays.

This trip was the outcome of the failure of the Chicago Automobile Club to stage its non-motor-stop night and day run from Chicago to Boston. Mr. Patterson was one of the prime movers in the projected contest, and when it fell by the wayside he decided to drive his own car under these conditions from Chicago to New York. He succeeded in all except that the motor stopped momentarily at Bryan, O., when filling with gasoline. Patterson had installed a small tank on the dash to supply the carbureter while the pressure was off the main gasoline tank for filling, and at Bryan the auxiliary tank on the dash was turned off a second too soon. With this exception the motor was kept running from start to finish.

The speedometer showed 1,025 miles covered, the route being by way of So. Bend, Toledo, Cleveland, Buffalo, Syracus, Albany, Poughkeepsie, and New York. Good weather was encountered all the way with the exception of rain from Syracuse to New York. Mr. Patterson carried two official observers appointed by the Chicago Automobile Club.

New Management for Pullman Company

YORK, PA., July 6—H. W. Hayden, of Detroit, who was recently elected president of the Pullman Motor Car Co. of this city, is in entire control of the activities of the company. The other officers of the organization retain their interests in the business but leave the active management to Mr. Hayden.

An Oldfield-Burman Match at Milwaukee Next Saturday

A Purse of $10,000 and Championship Title Said To Be at Stake—Big Program for State Fair

MILWAUKEE, WIS., July 3—Bob Burman, speed king, and Barney Oldfield, former wearer of the crown, will meet in a match race at State Fair park, Milwaukee, for a purse of $10,000 and the title on Saturday afternoon, July 11. The state board of agriculture, after much deliberation, granted the use of the one-mile dirt circle for the first of the Burman-Oldfield series. It was necesary for the board to seek an opinion from the attorney-general of Wisconsin as to whether or not the July 11 race would prejudice a contract made by the board with Ernie Moross for a hippodrome exhibition on September 14, the first day of the annual state fair. The state's attorney opined that there would be no violation of the agreement, and the race was declared "on". The state board will cut in on the gate receipts in a sum sufficient to cover any damage that may be done to the track.

George W. Browne, a Milwaukee dealer, is handling arrangements for the match race. He is well known in the racing game, having taken a leading part in the management of the Vanderbilt and Grand Prix at Milwaukee in October, 1912. While the program has not been definitely settled, it is known that both Burman and Oldfield will put on several exhibitions before the main event, which will probably be at 50 miles, and give Milwaukee and visiting enthusiasts a run for their money. In the championship event Burman will use the Peugeot which Goux drove in the last Memorial day 500-mile, while Oldfield will drive the Blitzen Benz II.

At the agricultural board meeting, it was decided to make September 14, the first day of the state fair, "automobile day". Ernie Moross' troupe of barnstormers will put on a half dozen events and there will be no harness racing on that day. On September 18, the closing day of the fair, Oldfield will put on a race against Lincoln Beachey in an aeroplane. At the 1912 fair Beachey raced Oldfield in a Knox and managed to come out ahead. The board has arranged for the most extensive outdoor display of motor vehicles ever held in the middle west as part of the general state fair exhibits.

Studebaker Averages 15.15 Miles a Gallon

BUFFALO, N. Y., July 5—The Studebaker six today finished its series of five 200-mile trips.

The fifth and final 200-mile run was run under most unfavorable conditions. Roads were wet and detours many. It averaged 15.2 gallons per mile and used 2 quarts of oil and 2 quarts of water. It used 13 1-4 gallons of gasoline for the trip.

The actual cost of operating the car, carrying six passengers, is $.0103 a mile. This figure is given on the basis of 1,000 miles of actual road travel, the total gasoline, oil and water cost for the 1,000 miles being added and divided into the total distance traveled.

The following tabulation gives the complete data on the five runs:

	Distance	Gasoline, gallons	Oil, quarts	Water, quarts
First day	204	14½	2	1
Second day	206.7	13½	2	3
Third day	189	12¼	1½	*1
Fourth day	200.6	12½	2	1
Fifth day	200.6	13¼	2	2

*Pint.

Average mileage per gallon of gasoline, 15.15 miles.
Average mileage per gallon of oil, 421 miles.
Average mileage per gallon of water, 470 miles.

A. A. A. Contest Rules for 1914 Promulgated

NEW YORK CITY, July 6—Several changes in the A. A. A. contest rules for 1914 have been made. Richard Kennerdell, chairman of the contest board of the A. A. A., has made a brief summary as follows:

Stock Car Rules

The rules governing speed competition of stock cars and stock chassis have been eliminated and a more simple method of registration of stock models for touring events has been provided. A less technical description of stock models must be filed with the contest board prior to any events in which the stock model is entered, and such certificate is turned over to the technical committee to check up the cars entered for competition in stock car touring events.

Classification

The Class "B" classification for stock chassis has been eliminated and a new subdivision has been made in the Class A Price Classification. Whereas formerly division 1A was for cars under $800, there are now two divisions, 1A for $450 and under 2A for $451 to $800.

In the same way three new classifications have been added to the Class C Piston Displacement Classification. Whereas formerly the smallest division was for cars under 161 cubic inches, the new classifications are:

Cyclecar	Division 1C	under 71 cubic inches
Light car	Division 2C	71 to 100 cubic inches
Small car	Division 3C	101 to 125 cubic inches
	Division 4C	126 to 160 cubic inches

The other divisions under Classes A and C remain the same.

Sanction Fees

Sanction fees remain the same with the exception that where heretofore events 100 miles or over on specially constructed speedways have carried a fee of $1,000 the following modifications have been made:

Road Races, Speedway Races, Beach Races, Track Races and Hill Climbs

No material changes have been made in these rules.

126. DIRECTION—Road races may be run in either direction over the course, provided, however, the pits must be located on the right side of the course in the direction in which the cars are traveling.

For Specially Constructed Speedways

Brick, concrete, wood, etc.	
100 miles and under, per day	$250
101 miles and over	1000
Dirt and other materials.	
100 miles and under, per day	250
101 miles and over	750
Dirt only.	
100 miles and under, per day	250
101 miles and over	500

Where programs are composed entirely of events for cars under 125 cubic inches piston displacement or $450 in price, the sanction fees are 50 per cent. of those regularly prescribed. Where such events constitute only a portion of the day's program, the full fees will prevail.

CREW—In all speed events 100 miles or over the crew of a car must consist of driver and mechanician, and all mechanicians must be registered in the same way as drivers have been required to register since 1910. Attractive gold pins bearing the registry number are provided for registered drivers and mechanicians.

NO INTOXICANTS PERMITTED—A new rule has been incorporated strictly prohibiting the use of intoxicants in contests, under penalty of disqualification.

Touring Rules

The distinction heretofore existing between contests of 6 days and under and contests over 6 days in duration has been eliminated, and new grades for Interclub contests and Economy contests incorporated.

GRADE I covers technical contests embracing preliminary and final examinations, tests of motor, clutch, gearset and brakes, with penalties for damaged or inoperative parts, lateness at control and repairs and replacements.

GRADE II imposes penalties only for lateness and work done.

GRADE III imposes penalties for lateness in arrival at controls only.

GRADES I and II may be conducted for stock or non-stock cars, but Grade III is open only to non-stock cars.

Sanction fees for Grade II contests have been reduced to $30 and for Grade III contests to $10.

Stock car touring events may be conducted under price classification or piston displacement classification.

Touring cars and runabouts may compete together for the same price without reference to passenger carrying capacity.

TIRE REPAIRS—No penalty for tire repairs and replacements, and the time consumed is added to the daily running time. Extra casings and tubes may be removed from competing cars in controls for repairs. Motors may be stopped during tire repairs without penalty.

Demountable rims or wheels may be used in stock car events only where cars are regularly equipped.

The time lost on account of traffic delays occasioned by railroad crossings, congestion in city streets, open bridges, obstructed roadways, etc., will not be added to the daily running schedule, but such lost time must be made up by contesting cars.

DAILY RUNNING SCHEDULE—An average speed of 14 miles per hour has been set for cars priced at $450 and under, the former schedules of 16, 18 and 20 miles per hour remaining applicable to cars of $451 to $800, $801 to $1600 and over $1600.

PASSENGER LOAD—All cars are required to carry at least one passenger other than the driver without regard to body equipment or carrying capacity.

Batteries

Dry cells for ignition or lighting may be replaced without penalty, the work to be done on the car's running time.

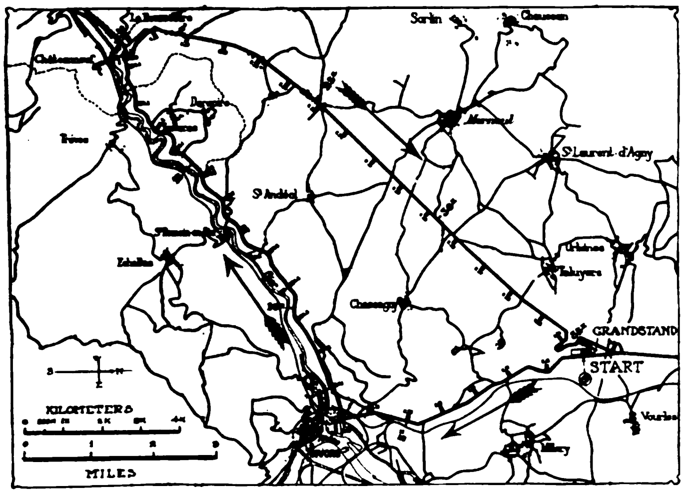
Replacing or recharging of storage batteries where charging generator is regular equipment will be penalized.

Replacing or recharging storage batteries where no charging means are furnished will be allowed without penalty.

Fixed Penalty Schedule

The fixed penalty schedule has been amplified to provide penalties for damaged or inoperative equipment such as self-starters, automatic gearshifts, two speed rear axles, lighting, shock absorbers, speedometers, horns, windshields, tops and similar accessories.

The rules have been simplified and rearranged, in so far as possible, so as to afford a more ready reference.



Map of the Grand Prix race course at Lyons, France, showing the difficult hairpin turns

All Cars Are of Special Design

(*Continued from page 65*)

The amount of speed that the new Fiats are capable of, considering that their weight is under the limit of 2,425 pounds, is proof that this company has worked hard to solve the light motor car, using cylinders 3.9 x 5.6 bore and stroke. The valve mechanism has been described. Lubrication is under pressure to the three plain bearings and to the other parts of the motor but no oil is carried in the base chamber. Two pumps, one driven off the magneto shaft and the other from the camshaft, respectively draw the oil from the base chamber to the tank and deliver it from this tank to the bearings. In this way all the oil supply is carried on the dash where it is isolated from the heat of the motor.

Front wheel brakes are used, which are slightly smaller in diameter than those on the rear wheels. They are expanding types but not encased. The motor and gearbox form a unit construction with a multiple-disk clutch entirely inclosed. Torque and radius rods are not used as the drive is taken through the rear springs which are mounted under the axle and directly under the frame members.

Fiat has a narrow dummy front radiator forming a guard against flying stones and with the radiator proper a few inches back of it. A pure streamline form is maintained with the gasoline tank entirely hidden.

Alda Has Cantilever Springs

The Alda normally carries the radiator on the dash, but has moved it to the front in its present racing machines and leaves an opening in the pointed bonnet so as to get cooling effect while conserving the general lines of its stock car. It uses a motor with 3.7 x 6.3 inch bore and stroke with sixteen overhead valves. The hollow crankshaft is carried on five plain bearings; and the connecting rods are tubular ones made out of B. N. D. steel. Pistons are machined out of solid forgings. The makers declare the motor develops 128 horsepower at 2,800 revolutions per minute. Variable splash lubrication is employed with a large reserve oil tank located across the frame members amidship.

Cantilever springs are set directly under the frame members and are a feature of the car, the only other car in the race to use this type of spring being the Aquila-Italiana. Alda has carried out the streamline body effect by using a pointed tail which forms a locker within which two spare wheels are carried in a horizontal position. The upper part of the tail is hinged. The gasoline is carried in the dashboard tank.

The Opel car with cylinders 3.7 x 6.3 and using sixteen overhead valves, carries the crankshaft on five plain bearings and like all of the cars with the exception of Delage uses a four-speed gearset. Direct is on fourth. At the rear of the motor is a cross shaft which drives the water pump on one end and the magneto at the other.

Piccard-Pictet Almost Stock

The nearest approach to a stock car in the thirty-eight entered is the Piccard-Pictet sleeve-valve motor, built under Argyll license. The stock construction has been changed in that timing and compression are special and the reciprocating parts have been lightened. The cylinders are 3.8 x 5.9. The chassis is shorter than stock and carries front wheel brakes. In other respects stock design is adhered to.

Schneider Has Renault Hood

The Schneider uses a very compact block casting and has its eight overhead valves operated positively without springs. The cylinders 3.7 x 6.29 are mounted on crankcase secured direct to the frame members. The hollow crankshaft of B. N. D. steel is carried on R. B. F. roller bearings, this being the only example of roller bearings for crankshafts in any car.

The radiator design is distinctive in that the radiator is carried at the front of the motor, but the bonnet is a Renault type, extending ahead of the radiator and having a big wire gauze covering set in the front. By this design the car looks like the stock Schneiders which have their radiators back of the motor, Renault fashion. With this new design the radiator is in a position to get the full air blast and yet is protected from flying stones. The streamline effect is carried throughout the rear.

Lyons' Grand Prix Course Is Ideal

The course is of a spectacular nature. It is roughly triangular, 23.3 miles, and has to be covered twenty times, giving a total distance of 46.75 miles. The grandstands are on No. 1 leg 100 or 150 yards from the turn. The situation is ideal. Opposite, and just below the level of the road, is the line of tire and gasoline pits. Half a mile across country is a hill the winding road of which forms a part of the third leg of the course.

No. 1 leg of the course is comparatively easy. No. 2 has eighty turns in 8 miles. It is the portion of the course on which brakes have to give the best of service. Four or five of the turns look and are really dangerous. The others are treacherous. They look innocent, but a fraction of a second's inattention would be sufficient to bring the car in contact with the wall of rock on the right-hand side, or hurl it down the embankment into the vineyards on the left.

120 Miles an Hour on Straightaway

At the end of the second leg there is a hairpin turn followed immediately by a winding climb a mile and a half long. It is followed by a perfect straightaway 7 miles long, of a switchback nature, on which speeds of 120 miles an hour should be attained. It is here that the value of a geared-up indirect drive will be appreciated. The straightaway finished, the drivers obtain a bird's-eye view of the grandstands in the valley below and commence their winding descent. At each of the hairpin turns the approaching leg is left open, so that a driver who has miscalculated his speed can run ahead for 200 or 300 yards. Stout wood barricades are put round the course at all points where spectators are likely to gather. Barricades are also put up in front of every house, even if it is an isolated one on a deserted open road. As a protection to drivers sand and cinders are banked around the outside of every turn to a height of 3 feet. A total of 150 tons of wood, having a length of 35,000 yards, is used to form barricades to keep spectators off the course.

Note.—All cars in the race were shaft driven

Tire Troubles at Sioux City

(*Continued from page 71*)

looked over and the break sealed. At all of these stops fuel and oil were supplied, much of the latter being necessary because of the leakage. The last stop at 170 miles was for 55 seconds to change a right rear tire. He was called off at 252 miles.

The second Stutz entry, driven by Barney Oldfield, made three stops before it went out of the race with a cracked cylinder. Barney's first stop at 144 miles was for oil, water and fuel. At his next at 146 miles he came to the pits to clean the radiator, which was not cooling properly, and he also removed No. 4 ignition wire, thereby cutting out that cylinder which contained the crack. He attempted to continue on three cylinders, but withdrew the next lap.

The two Sunbeams, driven by Grant and Babcock, did creditable work up to the time of their retirement. Grant made two stops for right rear tires and at 262 miles he broke a universal on the back stretch and was out. His teammate, Babcock, made four stops.

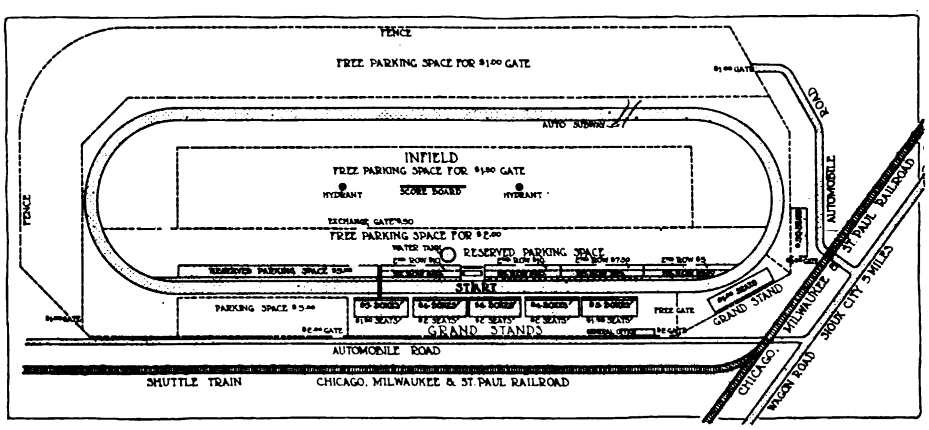
The second car to retire from the race was a Peugeot driven by Stringer. It broke a connecting-rod near the finish line at 86 miles. Previous to this a stop was made at 50 miles for a right rear tire, and considerable trouble was found in starting.

The first car to leave the course was the Mason, with Mason driving. At 4 miles he came in claiming no gasoline was flowing to the carbureter. He remained at the pits 30 seconds, and after leaving went one lap and again came to the pits with a spark plug in No. 1 cylinder blown out. This was replaced and Mason only drove 50 feet when he broke the driveshaft.

One of the local entries, the White six, driven by Shrunk, remained at the pits for more than 2 hours, repairing and replacing two bearings. The center main bearing broke and one rod bearing seized.

Another local car which ran in hard luck was Wetmore's Chalmers six, which made thirteen stops, most of which were for what was supposed to be carbureter trouble. The first stop was at 10 miles to change a right front tire, and the second at 34 miles for a right rear. The carbureter trouble began at 46 miles and it appeared that the fuel was full of water and dirt. The air line to the tank was giving trouble also. After making adjustments the car continued, but the motor still misfired badly. Two more tire changes were necessary at 64 miles, both rear tires being taken off. He was flagged off at 176 miles.

Burman was out at 160 miles with a broken crankcase, connecting-rod and piston. The bearing no doubt was not fed any oil, it seized, then bent the steel connecting-rod which left the crankshaft and punched through the crankcase. Burman made three stops before retiring, the first at 32 miles, when a left rear tire was punctured. His next was at 114 miles for a new right rear tire.



Map of the Sioux City Speedway, over which the 300-mile race was run

F & S

BALL BEARINGS

Finished 1-2-3

in the 1914 Grand Prix de France!

Time	Time	Time
1—Mercedes 7.08.18	2—Mercedes 7.09.54	3—Mercedes 7.13.15
Lautenschlager (65.55 m. p. h. for 467.5 miles.)	Wagner	Salzer

All three mounted exclusively on F & S Ball Bearings, defeating in this, the world's classic road race, the best racing creations of France, England, Italy and Switzerland, over a decidedly winding country circuit of 23.3 miles of 20 laps.

Thus does—History repeat itself again,
In this German Mercedes win;
For a stern chase is a long chase,
When F & S Bearings make the pace.

Factory Miscellany

COUNCIL Bluffs May Have Plant—That it would be practicable to manufacture automobiles in Council Bluffs, Ia., has been proven within the last few weeks at the Keys Bros.' Carriage factory at Twenty-eighth street and First avenue. Two sample cars were completed a few days ago and a thorough test has shown them to be equal to any make of the same size. The "Keys Car" is a five-passenger, 40-horsepower machine with a 112-inch wheelbase and a modern streamline body. The motor is from the Buda factory, four cylinders 4⅛ by 5¼. The body of the machine is from the Michigan Body works.

Excelsior Tool Co. Adds—The Excelsior Tool & Machine Co., East St. Louis, Ill., has begun the construction work on its recently announced addition and will soon seek the necessary equipment.

R-C-H Plant Bought—The power plant and some other buildings, all told a ground 200 by 400 feet, being part of the general plant of the bankrupt R-C-H Corp., Detroit, Mich., have been purchased by the General Ice Delivery Co., Detroit.

Carter Carburetor's New Building—The Carter Carburetor Co., St. Louis, Mo., of which C. O. Baxter is president, has bought a new factory building and will install equipment for the manufacture of carbureters, and also erect and equip a brass foundry on adjoining vacant land.

Another Ford Plant—The growth of the Ford Motor Co. of Canada, Ltd., is illustrated by the number of new branches being established. It is erecting a large plant on Christie street, Toronto, a site for a plant is being excavated at Montreal, and now comes the announcement that property has been purchased at London, Ont., for a new assembling plant.

Will Make New Spring—P. Walter Fay, of the Warren Garage Co., Worcester, Mass., has formed a company to start the manufacture of the new spring for motor vehicles for which he received a patent a short time ago. Daniel T. Higgins and John J. Barry have joined the company, and the springs will be turned out in a shop on Vine street for the present.

Reo's Three New Buildings—The Reo Motor Car Co., Lansing, Mich., has three new buildings under construction which will greatly increase the capacity of its plant. The additions will consist of a forge shop and power house, 96 by 225 feet; a machine shop, 95 by 560 feet, both one story, and a three-story erecting and painting shop, 144 by 256 feet. Machinery of the latest type will be installed.

Visiting Cambridge Plants—Many civic and other bodies are taking advantage of the opportunity to visit the big plants of the Gray & Davis Co. and the Ford Motor Car Co., located near each other on the boulevard in Cambridge, Mass. One of the recent gatherings at both places was that of Mayor Good, members of the board of aldermen and city council and the board of trade of Cambridge, who spent several hours going through both places.

$395 Car in Lansing—Lansing, Mich., is to have another automobile manufacturing concern, which will build a car to sell at $395. Those interested are Messrs. Thomas and Walls, who are busy just now with the incorporation formalities, the capital stock of the concern to be $250,000. The Chamber of Commerce, which had appointed a special committee to hear the promoters, heard a report from its members, which, after a thorough investigation, decided to provide the funds for the construction of a model car which is expected to be ready within 30 days.

Monorail in Buick Plant—A three-story fireproof building is being erected by the Buick Motor Co., Flint, Mich., for its enamel plant. In addition to the standard equipment of the modern enameling plant in the Buick building will be installed the monorail system for moving the raw material and the finished product to the various parts of the factory. There will be fifteen ovens and two high speed electric elevators of 4,000 pounds capacity each. There will be washed air ventilation, dustless floors, ice cooled drinking fountains of running water, well lighted and sanitary lunch and locker rooms and shower baths for the employees.

New Auto Tractor Plant—The Auto Tractor Co.'s new plant in Niles, Mich., is nearing completion. It is a one-story structure, 100 by 115 feet, with a monitor in the center having a clear span of 33 feet. The roof is supported by a traveling crane to serve the center bay of the building. The factory is located on the South Bend division of the M. C. R. R. Machinery will be installed within the next 10 days. The officers of the company are W. H. Zimmerman, president; F. J. Plyn, vice-president, and F. S. Hadfield, secretary-treasurer. The company makes a specialty of manufacturing farm tractors for attaching to all standard makes and sizes of automobiles.

Will Manufacture Tire Holders—The Rimolox Tire Carrier Co., Evansville, Ind., has been incorporated with $20,000 capital stock to manufacture tire holders or supports. The directors are M. A. Strouse, A. Harnishfeger and W. N. Erskine.

Electric Welding Co. Adds—The Electric Welding & Products Co., 2206 Clarkwood avenue, Cleveland, O., manufacturer of automobile supplies and screws, will build a one-story, 45 by 123 foot brick addition to its plant.

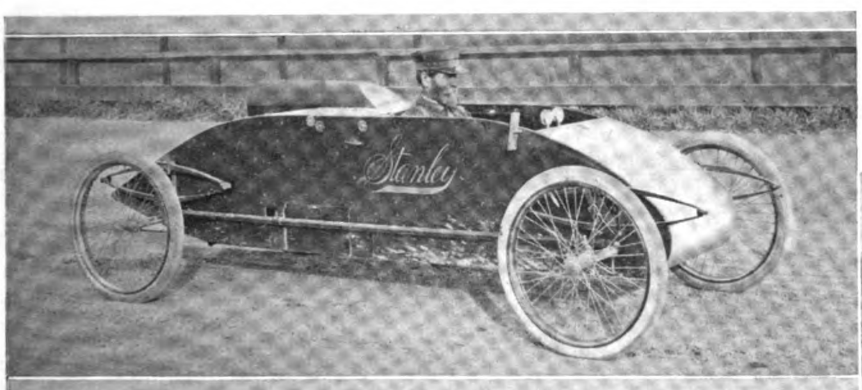
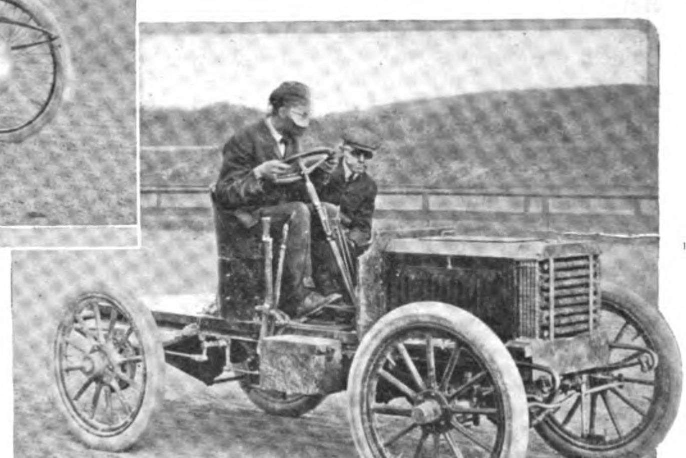
The AUTOMOBILE

New England a Factor In the History of Racing

Mishaps Brought Experience and Progress in Design and Construction—Forerunners of Modern Streamline Racers

By
James T. Sullivan



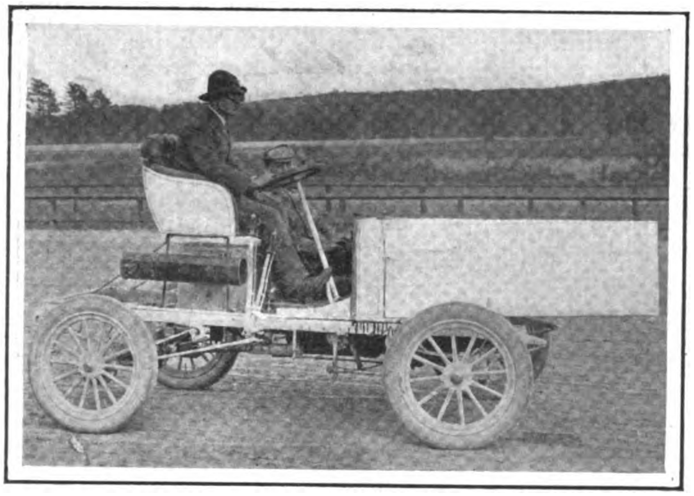


Above—F. E. Stanley in the Stanley steamer racing car in which he broke records at the meet at Readville, Mass., May 30, 1903. This was the first car of the kind ever built, the forerunner of those that swept Ormond Beach later. Right—J. L. Snow on his Peerless racer which made fast time in early Massachusetts races

BOSTON, July 11—When it was announced that the qualifying time for one round of the Indianapolis speedway was to be 1.42, and later when the cars tore around the track at an 80-mile-an-hour average or better, some of the men who participated in the first race meets in Massachusetts smiled at the thought of the difference between past and present. For New England, by the way, was in the van when it came to real racing and it furnished men and machines that made racing history in those days.

40 M.P.H. High Average for a Race!

Some of these men are still in Boston. From time to time they get together at outings and talk about the old days. At that time 1.42 was a pretty good average for a mile, not to mention that the Indianapolis distance is 2.5 miles. And 40 miles an hour for a race was splendid, only no one ever considered going that distance. Five miles was about the limit. At that time—we are going back now to 1902 and 1903—there was much eagerness and anxiety displayed in getting cars ready, but it was not the professional feeling that one finds now when a force of mechanics do a lot of the work. It was "do it yourself" the best way you could. And the finish of a race brought a lot of cheers mingled with laughter in which the losers joined as heartily as the winners. Also the private owners of the cars represented got excited and shouted for their favorite wilder than the fans at a ball game.



Webb Jay mounted on one of the early steam cars which made an excellent showing in the early days of racing

To go back to these first races the one that inoculated Bay Staters with the fever took place at the exclusive Country Club grounds in Brookline in 1902 on a half-mile track. To get into the club one must spurt blue blood when a vein is punctured, and so for some of the participants it was great sport to rub elbows with the élite. Larz Anderson, until recently Minister to Japan, and before that Minister to other countries, whose millions are many, and who by the way is one of the most democratic fellows one ever met, had become interested in racing about that time. He owned a number of machines, some of which he has yet, and so a race meet appealed to him. Of course star drivers were wanted. About that time Kenneth A. Skinner, a pioneer dealer and first president of the Boston Automobile Dealers' Assn., had won fame by making a round trip to New York with Albert Champion in 32 hours 22 minutes. His time for one way was 19 hours 15 minutes. It was marvelous. That was the time that the A. C. A. tour came to Boston in a couple of days. Harry Fosdick then jumped into the newspaper headlines by clipping 8 hours off Skinner's record, and he was the Barney Oldfield of the hour.

Half-Mile Race Was Too Long

Therefore the star attraction of the Country Club race meet was to be Fosdick, and a driver named Griffen, specially imported to drive the great Locomobile racer of those days. The race was booked to be a thriller as they both had steamers and all sorts of hair-raising things were expected. Anyway, the great moment arrived. When the flag dropped Fosdick was yelling "Wait a minute! wait a minute!" It seems his steam pressure was getting up beyond the danger point and he was trying to get his machine under control like a horse prancing about unmindful of a jockey's efforts to head the right way. Griffen shot off all right but, alas, Fosdick was left at the post. Meanwhile the spectators were watching the lone racer speeding around the half-mile track. He made the first corner all right, then the straightaway, but after that he began to slow up and finally he stopped. A half mile was too long even for him. So the great race blew up, to the merriment of everyone.

Big Two-Cylinder Motors Favorites

There was another big event carded, the special match between one of Alexander Winton's creations and a Pope Robinson. It was in this event that Larz Anderson was most interested, for he was the owner of the Winton. Two-cylinder motors with big cylinders were expected to do wonders, but even that race proved a bit tame after the start, for the drivers had to bother with their cars all the way and speed was out of the question.

There had been some races at Providence that year, too, and so the year following the Massachusetts A. C., a newly formed organization, decided to hold some races at the famous Readville track. This is a 1-mile circuit, and when in good shape it is fast for a dirt track. The club officials selected May 30 for the date, and so these events in 1903 really mark the first successful race meet in the Bay State. Looking back now over the old rules it seems strange to see the classification according to weight and with or without tonneaus. A stripped chassis, as it is known now, was not in evidence.

A New Radiator Every Day

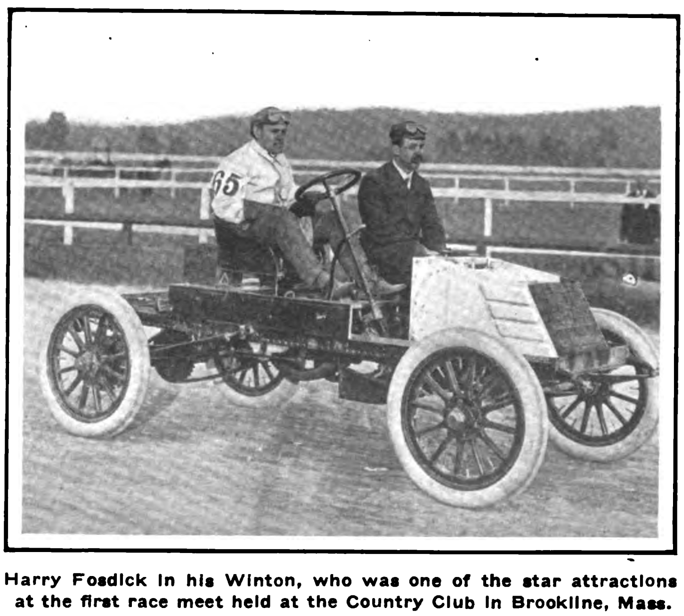
In that series of races there was a lot of fun getting ready for it, and participating in it. Jack Snow, now manager of the New England branch of the Peerless, had his troubles. It was late each day when he got a chance to go out to the track, some 20 miles from Boston. In fact, it was considered some feat in those days to make a non-stop run out or back. Jack was having trouble with the cooling system, and his radiator would shake so that it would spring aleak. He used a new one about every day. Finally he got a new radiator from the factory the morning of the race and he quickly put it on. But on the way out the motor would heat, and everywhere along the way where he could get water, he stopped and filled it up. Still it was no use. Finally the race took place and for 5 miles he drove around with a motor that got pretty hot. It was the same story in other events. He even borrowed a pump from another car and put it on, thinking that was the cause.

Excelsior in the Radiator

That night when he went over the machine he found that the radiator had come packed in excelsior, and a lot of it had got into the tubes so that they were choked. Of course such a thing could not happen nowadays.

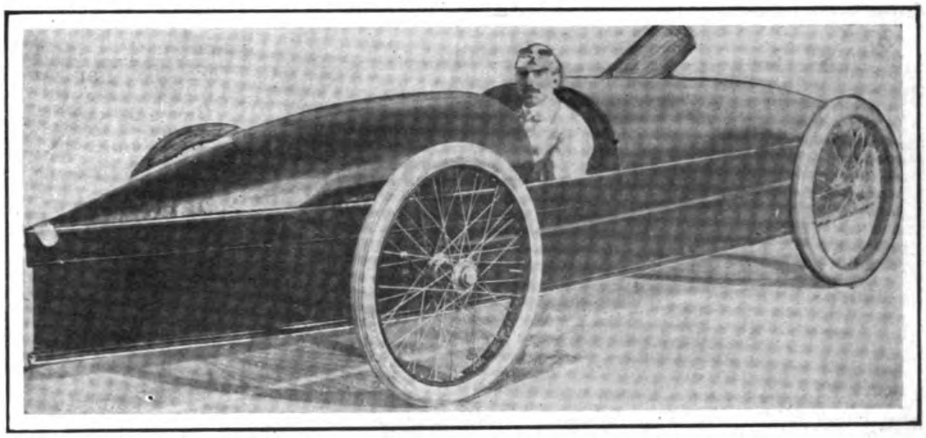
In those days when weight was the qualification tonneaus were taken off and put on with much speed. But that did not always do the trick. So the cars toted along several bars of pig iron or bags of sand to load into the machines to make them eligible for a heavier weight class. It used to be amusing to watch the weighing in and the dumping on or off some of the bars of pig iron or bags of sand, with the contestants watching to see that there was no jockeying with the weights.

In that first race meet there were some notable contestants. J. H. MacAlman, now president of the Boston Automobile



Harry Fosdick in his Winton, who was one of the star attractions at the first race meet held at the Country Club in Brookline, Mass.

Dealers' Assn., was a winner. L. R. Speare, ex-president of the A. A. A., figured in it. So did Frederic Tudor, one of the shining lights of clubdom in Boston, and the man who registered the first motor car under the Massachusetts laws, and who still carries every year the enviable 1 as his number plate. Then there was F. A. Hinchcliffe, now manager of the New England branch of the Winton, and A. R. Bangs, who sold the Franklin in those days. Louis S. Ross, the first man to win the Dewar trophy at Ormond, as well as a number of other prizes, was a participant.



Fred Marriott in the type of Stanley steamer which Louis Ross used in breaking records at Ormond Beach in the early days of automobile racing

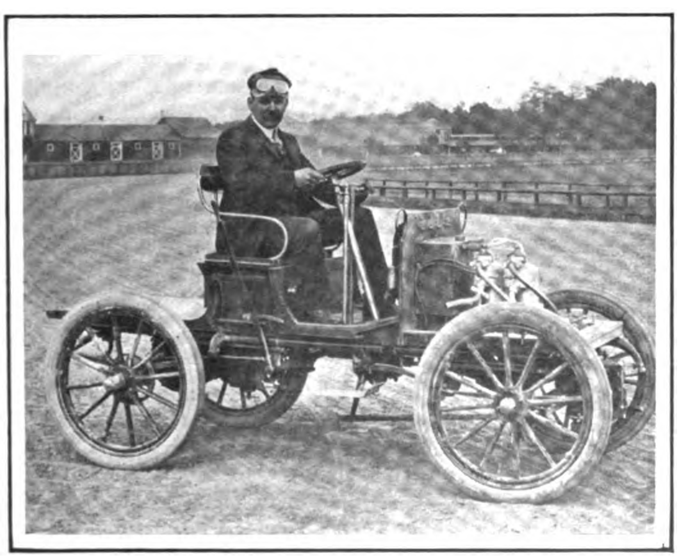
Steamers Beat Racers' Time

Webb Jay came on to show what his machine could do. He did not have the famous "Whistling Billy" then, but used another White steamer that was said to be fast. Then there was F. E. Stanley, the Newton maker, who electrified the crowd with his steamer when he made the then marvelous time of 1:02 3-5. Also George Cannon, a Harvard man, who was a pioneer racer with steamers, and whose home-made car held the record until Stanley took it away from him in this meet. George Reed, now the agent for the Vulcan in Boston, but handling the Stearns then, also raced and so did Fred Durbin, the man who by retiring when he got married, gave Fred Marriott the chance to drive Stanley machines and win honors at Ormond.

Cannon continued to cut a wide swath for a couple of years with his steamer, then he had a Grout steamer built and later ordered Louis S. Ross to construct one for him. This last machine was guaranteed to do a mile in 25 seconds, and it had two boilers and a double motor. But Cannon never called for it. He dropped out of sight and has not been heard of in racing since. Ross got tired of racing after some of the cleaning up Ormond and he has quit racing, too. He is now in the railroad fuse business in Newton. Skinner is renting cars in Boston.

The First Pursuit Race

It was an interesting collection of cars, too. There was the Stanley close to the ground; the Cannon machine with its smokestack, and the drivers in front; the others with long and short hoods. Most of the events were limited to 5 miles, but there was one event that exceeded the limit. It was a pursuit race, and the two stars, Skinner and Fosdick, fought it out. The idea was borrowed from Australia, it seems. Skinner had a De Dion and he started from the wire while Fosdick was over on the other side at the half-mile mark. When the flag dropped it was Fosdick's job to catch Skinner or Skinner's job to overtake Fosdick. There was much excitement, as each driver had a lot of friends, and when passing the wire they were cheered and urged to speed up. Fosdick had more power, however, and mile after mile brought him nearer to the foreign car until finally he caught up with Skinner after going 9.5 miles. It was hailed as a great American victory. The time was 12:56 4-5.



Kenneth A. Skinner in the imported De Dion racer which he drove in the first pursuit race, which was practically the only event exceeding 5 miles in distance in the early New England race meets

Introduction of Odd Racers

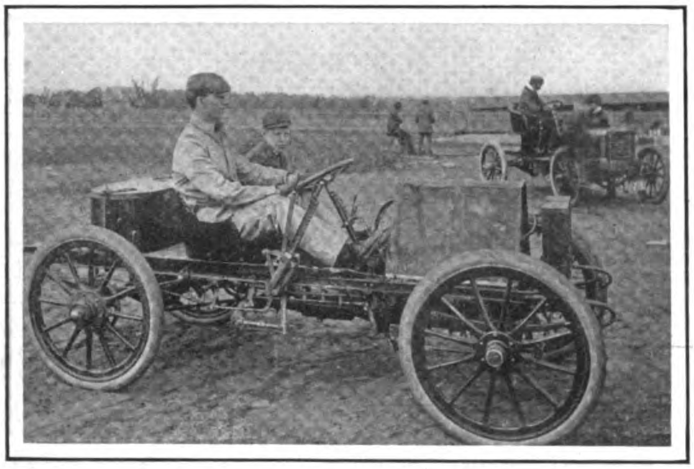
However, the star event of the day was the record-breaking achievement of F. E. Stanley, and the introduction to racing of the small cars that got all sorts of names from "woggle-bugs" to "torpedoes" from the racing scribes. It is interesting to look back now and quote from the papers of that date extracts about the race. Cannon had made 1:05 1-4 at Providence for a mile, and he and Stanley were invited to try to break that mark. So it was a special match. Here is what the Boston Globe said about it the next day:

"Terrific Speed of Racing Marvels

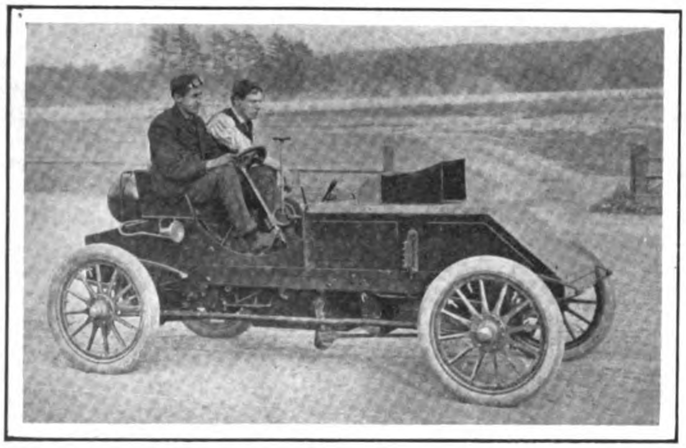
"Owing to the terrific speed at which these racing marvels travel it was deemed unsafe to start them together and the officials decided to run them against time. Roars of applause and the tinkling of automobile bells greeted the veteran Mr. Stanley as he prepared for his trial. His racer, setting close to the ground and shaped like an inverted torpedo, presented an odd appearance as it slowly moved up the track. Mr. Stanley, sitting in the middle, with just his head showing above the graceful curves of the bow and stern, resembled a gunner on a duck-shooting expedition more than anything else.

The Record Still Unbroken

"Without any apparent motion on the part of the operator the thing in red shot forward, emitting clouds of steam. Thrice did he circle the track and then the masked head nodded to Lon Peck, the starter, for the word. A pistol report rang out and the race against time was on. So terrific was the pace that few realized that the inanimate object was tearing around the track at such speed until car and man entered the home stretch, when the thousands broke forth in applause. The time was announced as 1:06, and the crowd relapsed, a trifle disappointed, but still hopeful of seeing the record broken.



Another view of John L. Snow mounted on one of his Peerless racers which upheld the prestige of the gasoline car in the early days of racing in New England



Charles Grout in a Grout steamer which made fast time in the early days of racing when rivalry between gasoline and steam driven cars was at its height

"Another low, rakish craft appeared on the scene. Every superfluous ounce of weight had been removed by Mr. Cannon for his trial, and his pet was in perfect trim for this great event. With the designer was F. L. Marselis, Jr., who added ballast as well as other assistance. The Cannon machine seen above the heads of the throng lined along the home stretch looked like the back of a dug-out, its smoke funnel projecting the least bit backward. The occupants sat in front of the boiler and were partly shielded from the wind by the long, low projecting bow. After a few times around the word was given and away sped the Cannon ball. Up to the first turn with a rush everything looked hopeful for a new record, but a wider detour on the turn lost some time, and when it reached the stretch it was going like a phantom. But 1:06 was the time announced and so far the race was a dead heat.

"Another race of a different class was decided while the boilers and tanks were filled and again Stanley came forth. This time, with the grace of a serpent, the racing contrivance glided down the stretch and flew around the turn. Into the back stretch darted the steamer, and down past the half mile post it shot with the velocity and certainty of an arrow. Intense silence reigned, as with unabated speed the torpedo went into the last turn. Not an inch did the machine swerve, Mr. Stanley holding it as close to the pole as he could with safety.

A New Record Made by Stanley

"With a whirr and a slew the low-clinging object appeared in the home stretch leaving a trail of steam and dust. Low murmurings grew in volume until they reached a great shout and the bells, gongs and horns took up the din as man and car neared the goal. Like a flash it was all over and then a hush fell over everything as the crowd waited for the official time. When the announcer shouted the time 1:02 4-5 there was a mighty cheer and the throng waited until the record-breaker sped around the track again. Mr. Stanley modestly acknowledged the great reception as he waited for Mr. Cannon to make his second try. Although the latter worked his steam car for every ounce, the best he could do was 1:04 2-5, breaking his own record, but 1 3-5 seconds slower than Mr. Stanley. So a new king was crowned."

Interest Centered in Getting the Pole

In a special match between Webb Jay and Frank Durbin, the former's car was put out of commission due to the gasoline catching fire, and so Durbin modestly refused to accept the win without competition. The races were pretty well contested, and there were not many runaways. The driver who got the pole had an advantage, for he could hug it and not cover so much ground as the fellows on the outside, and so the interest was centered in stealing the pole from each other. Then there would be a shout.

In those days the steamer and the gas car were very much in evidence and there was great rivalry. They had outclassed the electrics which, by the way, won the first race meet ever held, that at Providence some years previously. Following the 1903 events at Readville, which were a big success financially for there was an attendance of some 10,000 people, a big throng for those days, motor races became a yearly feature by the Massachusetts A. C. and later by the dealers themselves, and then the Bay State A. A. Sometimes there were two meets a year. But of late years they have been abandoned for lack of interest.

English Engineers To Discuss Self-Starter

LONDON, ENGLAND, June 29—At the last council meeting of the Institution of Automobile Engineers, held at the headquarters at 13 Queen Anne's Gate, the program for the November session of the institution was finally decided. The meeting will open with the presidential address by Col. H. C. Holden. One of the papers to be read will be on the "Position of the Self-Starter in America," by one of the members of the Society of Automobile Engineers of America, who will be in England in November.

Other subjects to be dealt with will be "Lubrication of Motor Cars," "Some Experiments on Benzole," two papers on "Aspects of Commercial Vehicles, Gears and Gear Cutting," "Worm-Drive and Power Expended in Flight." A number of the members of the I. A. E. are contemplating a visit to Belgium this summer. More than thirty have already signified their intention of taking part in the trip.

Safety Society to Test Rear-End Signals

NEW YORK CITY, July 15—Rear end signalling devices for automobiles wil be given a public test in the near future by the Safety First Society. There are many devices of this kind, several of which are ingenious, indicating not only the intention of the driver to slow down or stop his car, but also which way he intends to turn, whether to the right or left. These devices are said to be in general use abroad.

Workmen Call Off Westinghouse Strike

EAST PITTSBURGH, PA., June 14—The Westinghouse strike at East Pittsburgh has been called off by the workmen, the day set for returning to work having been set for Monday, July 13, a large number of men, however, reported on the Friday and the Saturday preceding. The works are now running full time.

Bosch Now Produces Rushmore Systems

Fig. 1—New Bosch starting motor

Rushmore Generators and Starting Motors Added to Bosch Line—Complete Systems Now Available for Every Requirement

THE absorption of the Rushmore interests by the Bosch company places the latter in a position to supply complete electrical equipments for any car on the maiket. Previous to the combination the Bosch company had been at work on generator and starter designs of all types. The introduction of the Rushmore sliding-pinion flywheel starter into the Bosch line makes it possible to meet all requirements.

At present there are eleven designs of Bosch generators and three Bosch starting motors. The Rushmore designs, which will henceforward be known as the Bosch-Rushmore models, comprise three generators and four sizes of starting motor. The Bosch models are designed for operation on 12-volt circuits while the Rushmore machines are adapted for 6-volt installations.

So far, the only car to be completely equipped with lighting, starting and ignition as standard by the Bosch company is the Marmon. Figs. 2 and 3 show respectively the application of the generator on the pump shaft and the starting motor on the crankcase at the side of the flywheel in this particular installation. The simplicity of the Rushmore method is noticeable in Fig. 3, the motor being supported on an arm projecting from the crankcase. The pinion on the end of the armature shaft, overhanging the teeth on the flywheel is also clearly shown. When not actually turning the flywheel the starting motor is completely isolated, suffering no wear and causing no friction.

Generators of All Types

The several designs of generator are necesary to meet the different requirements both of speed and possible fitting positions on various types of engines. Three of the Bosch generators are shown in Fig. 4. That at the left is intended for drive by chain through a pinion at one end of the armature shaft. It will be noted that the shaft at the other end does not project through the casing. In this respect this design differs from the center illustration. Here the shaft passes right through the casing and so enables it to carry the drive to the magneto as in the Marmon installation, Fig. 2. Where the crankcase has not been specially designed to take such a generator in this position between the pump and magneto, the generator at the right, Fig. 4, is suitable, being provided with a base which is identical with the standard magneto and with the shaft center at the same height above the base. To meet the exceptionally low armature position it was necessary to use a two-pole field magnet having the

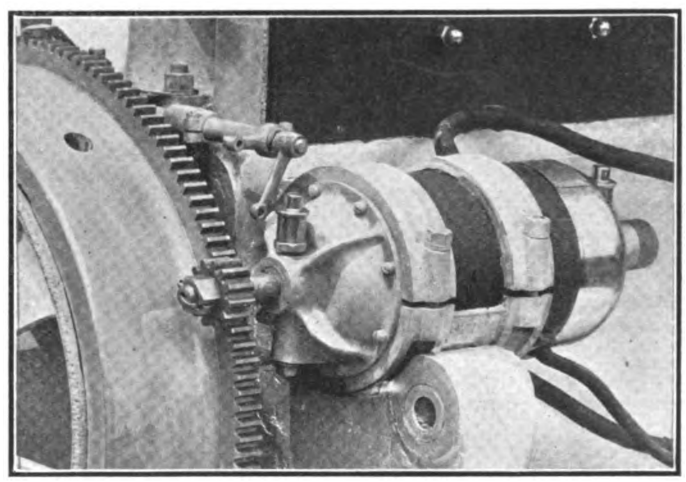

Fig. 3—Application of the Bosch-Rushmore starting motor, which operates directly on the flywheel, to the Marmon engine. Note the starting pinion, which is attached positively to the sliding armature shaft

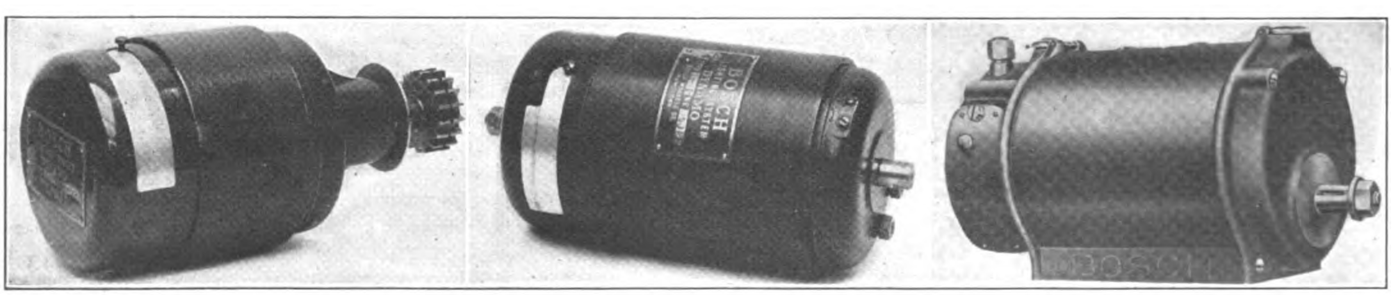

Fig. 4—Three types of Bosch lighting generators. At the left, for driving by chain. In the center, for insertion in a shaft line, for which purpose the armature shaft is carried through the casing at both ends. At the right, a special model with standard magneto base and low position of armature

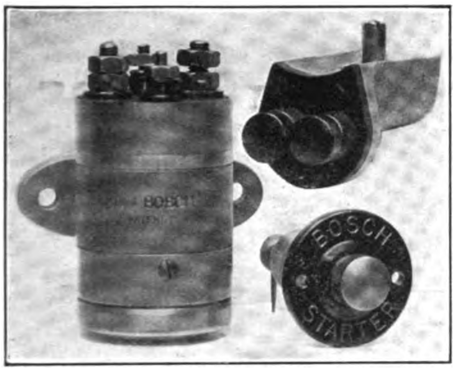

Fig. 5—Bosch electrically operated starting switch, which connects the starting motor to the battery by pressure on the small starting button at the right.

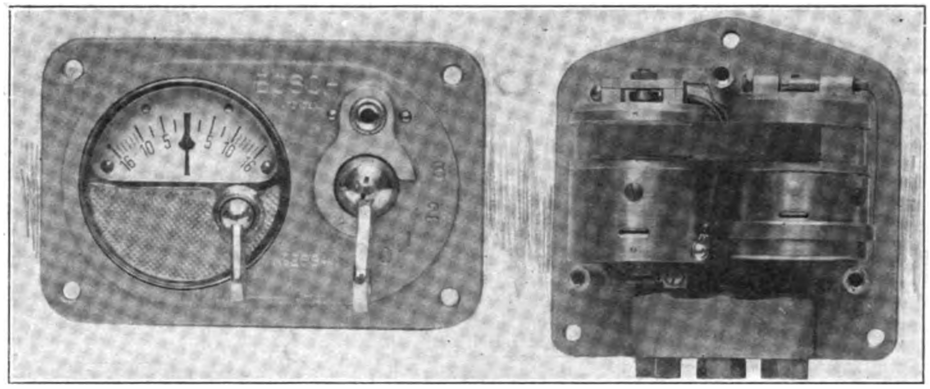

Fig. 6—At the left, instrument board for the Bosch system. The dial registers either amperes or volts. The switch arm is provided with a lock. At the right, the carbon-particle regulating device for the generator circuit, with the cover removed

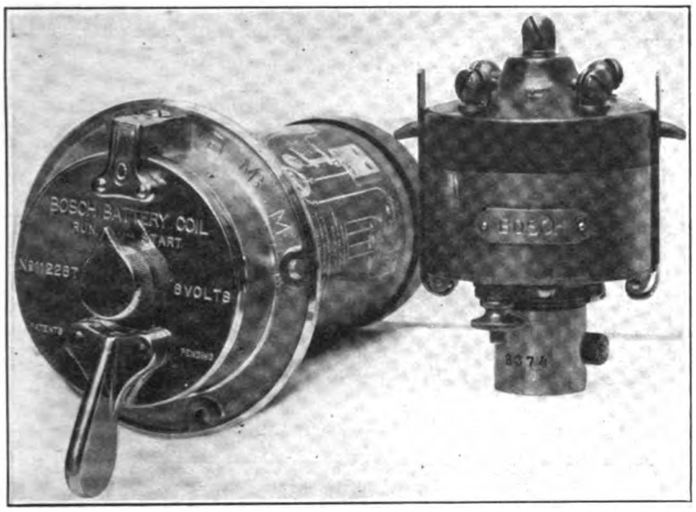

Fig. 7—Bosch battery-magneto switch and coil for dash mounting

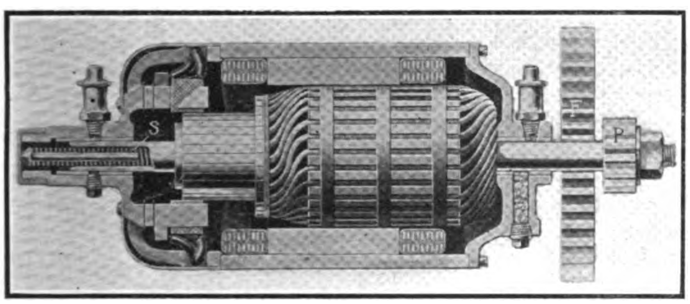

Fig. 8—Section through Bosch-Rushmore starting motor, showing displaced armature, which automatically draws the starting pinion into mesh on applying the current

field coils all located above the armature. In some of the types a gear is contained in the end cover.

Generator Control

Control of the current in the generator circuit in the Bosch installation is effected by the use of a solenoid regulator in the field circuit and a carbon-particle resistance, Fig. 6. The latter is contained in a compact case which can be conveniently located behind the dash. It is provided with a dust-proof cover. By tightening or loosening the nuts which regulate the pressure of the carbon particles any resistance can be obtained to suit individual running and lighting conditions. The battery used is known as the Bosch-Elba and is an Elba battery adapted to the requirements of the Bosch company.

Besides the carbon regulating device which can be located anywhere, there is a combined instrument and lock switch, Fig. 6, at the left for placing on the dash. The small lever below the dial is moved to one side or the other to read amperes or volts, while by locking the handle of the other switch it is impossible to operate anything electrical on the car.

Overrunning Clutch Used

The Bosch starting motors are of the overrunning clutch type and in order to insure correct switching in of the motor in the circuit the starting switch is not operated directly but through the agency of a small pilot switch. In Fig. 5 the cylindrical casing contains the electrically operated starting switch. Pressure on the small starting button at the right causes the contacts in the main switch to close, thereby connecting the motor directly with the battery circuit. The Bosch starting motor, Fig. 1, weighs 35 pounds and is 10.25 inches long by 5.85 inches diameter.

The small switch at the upper right, Fig. 5, is fitted on cars where it is desired to retain the starting crank. When cranking up, this switch automatically cuts out the magneto and connects the battery side of the ignition system. Immediately the engine fires the battery current is replaced by the magneto, also automatically. The dash coil and battery-magneto switch, which is another unit in the complete Bosch equipment is shown in Fig. 7.

Regulation of the Bosch-Rushmore generator is by means of an iron wire resistance or ballast coil placed across a series bucking winding on the field poles. A peculiarity of iron wire in an electrical circuit is that of suddenly increasing its electrical resistance when heated to a certain critical point. By so proportioning it that the heating is accomplished by the current itself the iron wire coil is made to act as a sort of electrical brake on itself, weakening the main fields and so cutting down the output of the dynamo.

Rushmore Principle Retained

No radical alteration has been made in the principle of operation of the Rushmore starter. In this method of starting the engine the motor is applied to the flywheel through a single pinion in mesh with teeth on the periphery of the flywheel. The means of bring the motor pinion into position for starting is unique among electric motors for this purpose. In applying the current the armature, which is held out of its working position by means of a spring at the end of the shaft is pulled up into the fields, carrying with it the pinion on the end of the armature shaft which then meshes with the flywheel and starts the engine. A section, Fig. 8, of the Bosch-Rushmore starter shows the Spring S at one end of the armature shaft and the pinion P at the other.

The Bosch-Rushmore starting and lighting system will be used on probably 80 per cent. of the installations. This in conjunction with the Bosch magneto and ignition systems constitutes a complete electrical equipment.

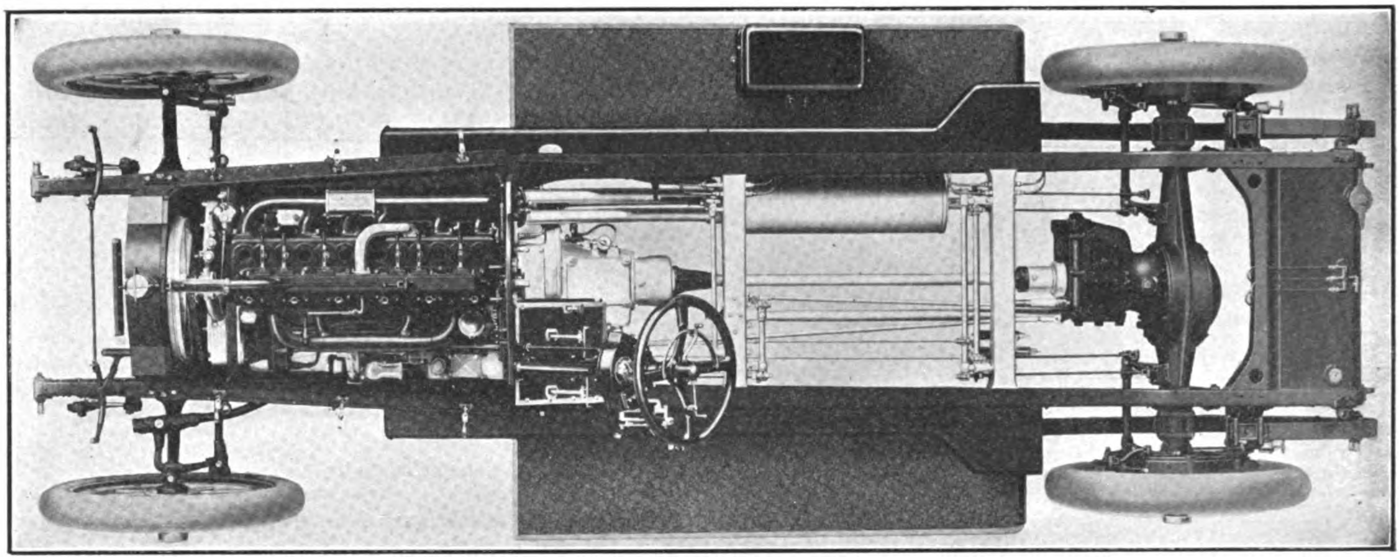

Fig. 1—Plan view of the chassis of the Packard 3-38 6 cylinder car for the 1915 season

Packard Continues Two Sixes

Changed Lamps and Carbureters —Separate Ignition and Double Exhaust Systems Continued

FOR this season Packard will continue its two sixes with but minor refinements. They will be known as the 3-38 and the 5-48 and, as the names suggest, will be practically continuations of the 2-38 and 4-48 of last season.

In general appearance they are practically the same as heretofore, having the same lines, and features such as the Packard form of radiator and sloping hood, the special type of bodies built in the Packard shops and so on.

Mechanically, too, there is little difference. General construction which has always been associated with the Packard chassis is still adhered to throughout. There are two main units, viz., the motor unit, comprising the power plant and clutch, and the rear axle unit, which consists of the final drive, gearset and differential gears.

Motors are practically identical with those used in the previous cars. They are both of the L-head type with cylinders cast in threes. The 3-38 has a bore of 4 inches and a stroke of 5½ inches, giving it an S.A.E. rating of 38 horsepower, while the 5-58 with its dimensions of 4½ by 5½ inches is rated by this method at 48. The company uses these ratings in designating the cars, but their maximum power outputs are 65 and 80 horsepower, respectively.

Headlamps Are Changed

There is one change in the outward appearance of the cars which is distinctive. This is the head lamp design. Each of the headlights has an auxiliary headlight with a separate reflector below the main lamp. The smaller lamp is an integral part of the other. These auxiliary headlights are designed for city driving or for meeting cars on the road but it is pointed out have the added advantage of being supported near the ground so as to throw light on the road ahead. With the addition of auxiliary headlights, the side lamps are reduced in size and are now designed to be used only when the car is standing at the curb or for driving in cities where headlights of any kind are prohibited The tail light and license tag illuminator have been replaced by a combination tail light and license light on the left rear fender.

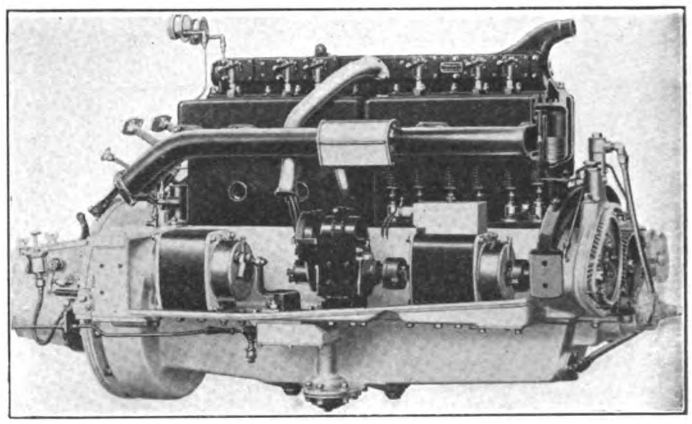

Fig. 2—Right side of the 3-38 motor with cut-away view in front

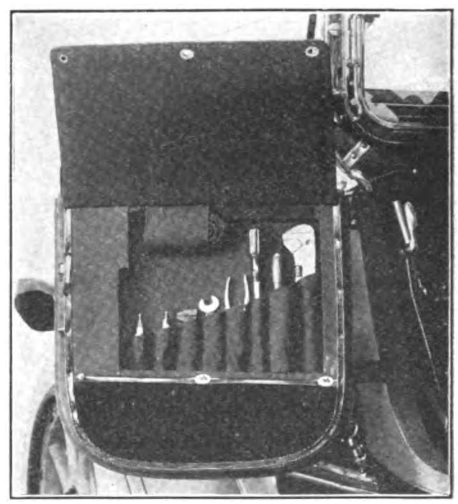

Fig. 3—Tool compartment in left front door

Though of the same operative design, the carbureter body has been changed in design so as to afford a housing for the auxiliary air valve. The opening in the housing is turned to the rear of the motor, thus reducing to a minimum the chances of getting dirt in the carbureter. Other minor changes are the increasing of the size of the radiator on the 3-38, the making larger of the gearset on this same model and the increasing of its motor's valves to 2⅛ inches.

Taking up the constructional details of the 3-38, the wheelbase is continued at 140 inches, which gives ample length for any desired type of body. Tread is standard at 56 inches, while the overall length of the seven-passenger car is 187.5 inches.

The engine has its valves all on the right side and completely enclosed. These are of nickel steel, mechanically operated from the camshaft and interchangeable. The inclosing covers are of aluminum and oil tight. Pistons fitted with three rings each are conventionally linked to the crankshaft by drop forged I-beam connecting-rods. The crankshaft, carried on seven large size main bearings attached to the upper half of the crankcase, is so mounted and its proportions such that no vibration is possible, making for quietness and smoothness of running.

Crankcase Split Horizontally

The crankcase which is conventionally split into two horizontal sections, has cast webs integral with the upper section on either side. These webs extend to the side members of the frame, and act as mud aprons, preventing any mud or water from splashing up onto the motor parts.

The hot water jacketed inlet manifold on the left side of the engine is continued. This has four openings into the cylinders, two for each block of three. These passages must go across to the valve side, and in running through the water jackets, assist further in fuel vaporization. The specially constructed double exhaust manifold is also continued. This has a separate passage for the burnt gases from each block of three cylinders so that there is no overlapping of the exhausts. There are consequently two pipes connecting from the rear of the header and running down to the muffler.

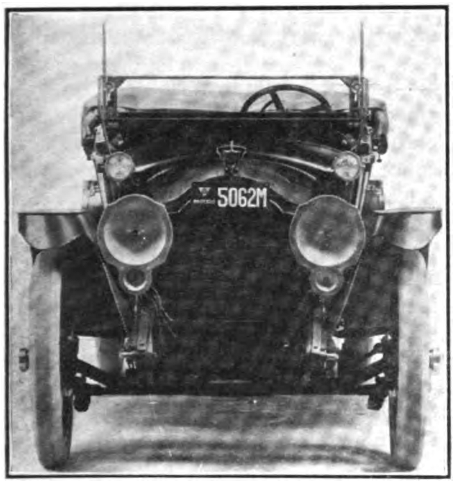

Fig. 4—Front view of Packard 3-38 touring car, showing new headlights

As on the previous car, the ignition system is entirely independent of the lighting and cranking system. A Bosch duplex magneto is located on the right side of the engine.

The oiling system is unchanged. Lubrication is by force feed from a gear driven pump, located in the crankcase. This pump is driven by worm gear on the camshaft.

Packard-Bijur System Continued

The Packard-Bijur cranking and lighting system is retained with slight refinements. The cranking motor and the generator are separate units. They are both located on the right side and are readily accessible. The generator is driven by a shaft from the front gears and operates at 1½ times crankshaft speed, generating at speeds from 10 miles an hour and giving its maximum voltage at 15 miles an hour.

The cranking motor which has capacity to turn the engine at 100 revolutions a minute when the latter is warm is geared at about 19½ to 1 to the flywheel, and a pedal under the driver's heel operates the shifting mechanism and sends the current to the instrument for starting purposes.

Back of the engine is the dry plate clutch which is housed in unit with the power plant, its case bolting to the crankcase. The casing plates are faced with a special friction material while the shaft plates are of metal with ground faces. The driveshaft, which is uninclosed, is fitted with universal joints and drives from the clutch directly back to the gearset in unit with the rear axle.

Three forward speeds are afforded, while the rear axle itself has a pressed steel housing, and contains worm-bevel gears which were brought out first by the Packard company. These are a combination of the bevel type and the worm, the gear faces being curved so that they engage with a rolling action, giving contact throughout the engagement and making them noiseless.

The springs are of the usual form—half elliptic in front and three-quarter in the rear. They are underslung from the axles, giving a somewhat lower hanging of the frame. The spring sizes are 2¼ by 40 in front and 2½ by 53 in the rear.

The regular line of Packard bodies is still featured. There are all types of inclosed cars, as well as distinctive phaetons, and touring cars of the open type. Equipment is complete and prices remain unchanged.

Tires are 26 by 4½ inches in front and 37 by 5 in the rear.

The 5-48 has a wheelbase of 144 inches, and incorporates all the features of the 3-38 with the added advantage of more surplus power. The specifications of the 3-38 cover the 5-48 with the exceptions that all tires are 37 by 5, cooling water capacity is slightly greater, and front springs are ½ inch longer.

The appearance of the 5-48 is almost identical with the 3-38, bodies being interchangeable.

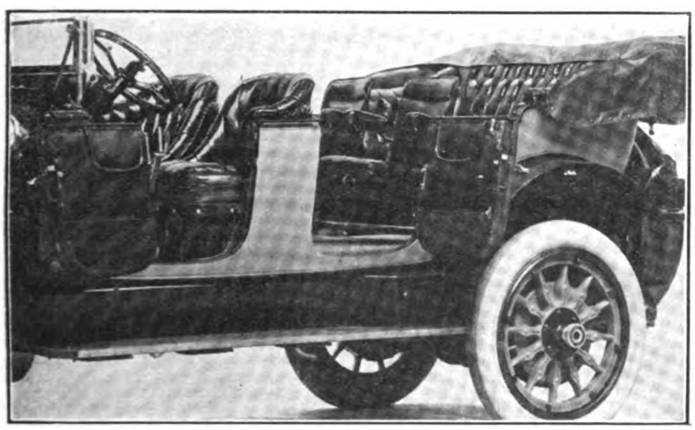

Fig. 5—Seating arrangement adopted in the Packard 3-38

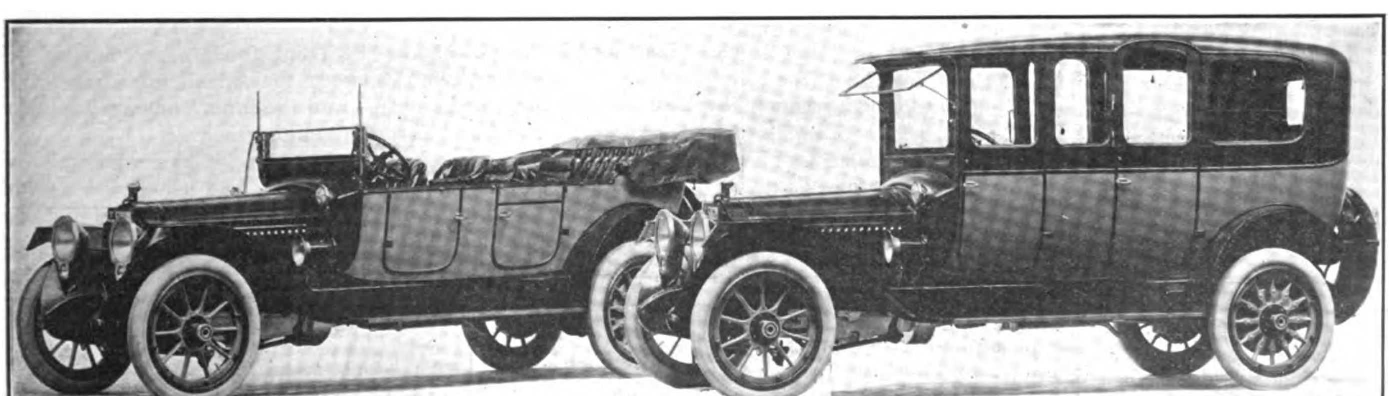

Fig. 6—Left—Packard 3-38 touring chassis with six passenger saloon touring body. Right—Touring chassis with limousine body

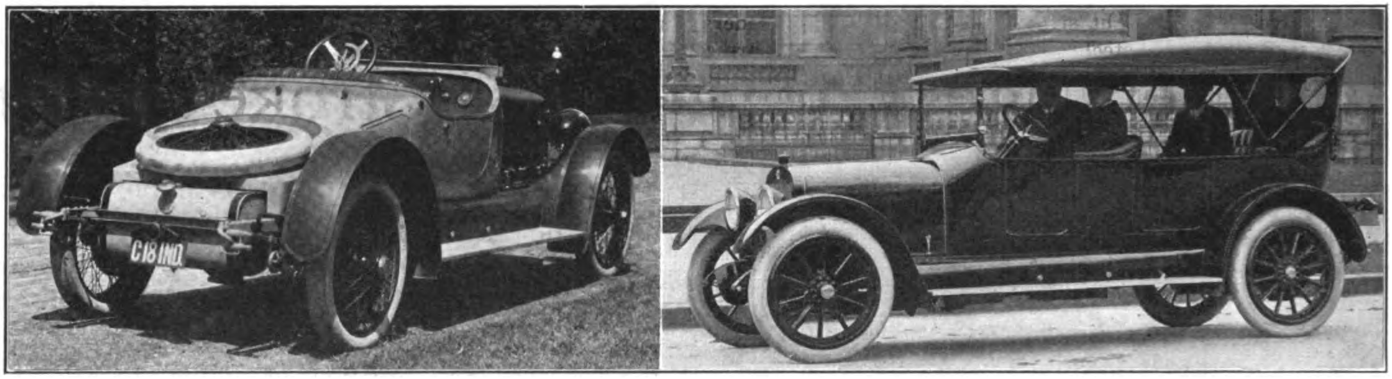


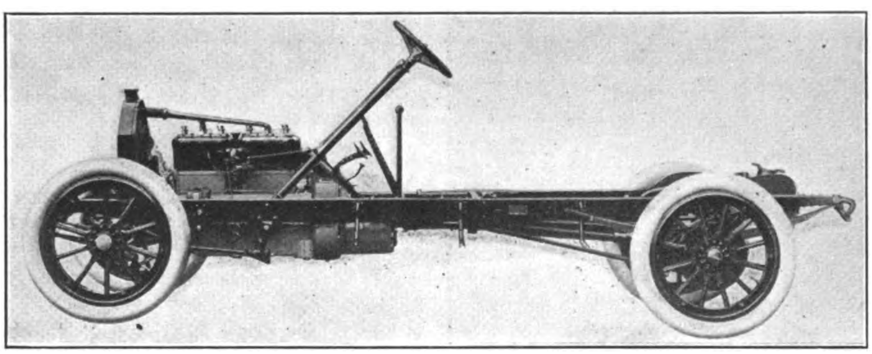
Left—Rear view of new Premier roadster. Right—The new touring car

Premier Continues T-Head Motor

PREMIER will continue the T-head model for 1915. Under the name of 6-49 this chassis will be a continuation of the 6-48 of the previous season but will be featured by a new roadster of racy lines with provision for carrying on the rear deck an extra wire wheel or two spare tires in an inset circular space into which they fit. The only mechanical change of importance in the chassis is the use of long semi-elliptic springs at the rear in place of the three-quarter elliptic. This has necessitated a few frame changes in order to meet the requirements of suspension.

Rather unusual factory equipment are the shock absorbers and recoil straps which are fitted. These, together with the rubber bumpers and the 60-inch semi-elliptic rear springs are designed to give maximum easy riding. The equipment also includes the Golde one-man-top, single piece ventilating windshield, Warner speedometer, and so on. Wire wheels are offered for the touring cars at $80 per set of five, but on the roadster either wire or wood wheels will be specified.

Starting and lighting is by the Remy system while an Eisemann magneto is used for ignition. The two- and five-passenger bodies will sell for $2,385 and the seven-passenger for $2,435 with full equipment.



Side view of chassis comprising 1915 Premier line

Cylinder dimensions of 4 by 5½ inches give the engine an S.A.E. rating of 38.4 horsepower, which is rather lower than the actual power delivered by the engine, the manufacturer stating that it delivers from 48 to 70 horsepower. Triplet casting of the cylinders permits placing the three cylinders close together, making a minimum distance between main bearings and center bearings. Lubrication of the motor is a circulating system with a constant level splash maintained by a gear driven pump. There is a sight feed glass on the dash. In the lower half of the crankcase are moulded transverse troughs. These have partitions between them so that the dippers on the ends of the connecting rods dip into the oil on any grade below 27 per cent. The oil which overflows from the troughs drains into the reservoir in the rear, and again is forced back into them. Pockets in the bearing journals catch the oil and feed it direct to the bearings through the oil holes.

Valves are completely inclosed and the push rods have 1-inch rollers which are ground inside and outside. The flywheel is completely inclosed and the whole T power plant is suspended at three points. The three-speed gearset is in an oil-tight housing and the gears are cut from nickel-steel forgings, the shafts running upon annular ball bearings. The ends of the transmission shaft are provided with stuffing boxes which prevent leakage of oil. The rear axles are made under the Premier patent and are generally termed a three-quarter floating type, inasmuch as this carries none of the load, but the shaft cannot be pulled out of the housing without disconnecting from the differential pinions. The Premier people call it "90 per cent. floating axle." It has an internally ribbed center housing so that truss rods are dispensed with. Handholes in the rear of the housing permit the gear to be adjusted to take up wear. The brake drums are an integral part of this clutch and hub arrangement. The internal brakes are operated by a pedal, and are steel shoes. The emergency brakes are external and are steel bands covered with Raybestos. The brakes altogether provide 526 square inches of braking surface. Tires are 36 by 4½ inches in size, although 34 or 36-inch wheels are offered on the touring car as an option.

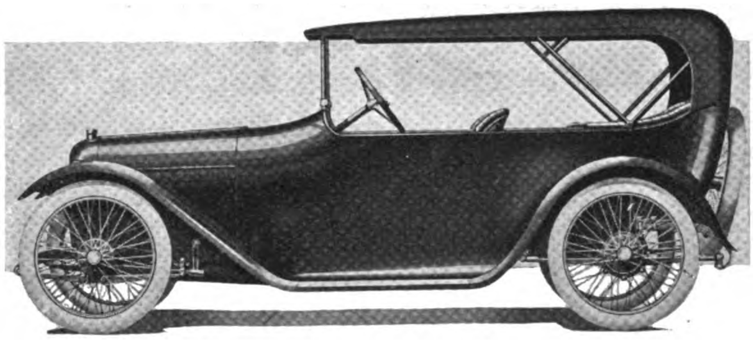
The framework is of oak braced with steel over sheet metal panels. Special protection is provided against rattling of the hood, and the front fenders are flanged to make a rigid connection between the splash guard and the car. All fenders are crowned and the inner ends are brought down several inches below the running boards.

In the touring car spare tires are carried in a cradle at the rear, which provides for two extras. The headlights are of the two-bulb type, providing brilliant lights for country driving and less intense ones for the city, this doing away with any side lamps. There is a combination tail and license lamp, an instrument lamp, and inspection lamp, all being independently operated. A motor driven tire pump is provided which is gear driven from the engine. The steering column which is on the left side is provided with a carbureter air adjustment.

Fischer Light Car Has Long Stroke Motor

Three Body Styles Supplied in Streamline Design—Deliveries To Be Made August 20

FISCHER is the name of a small car built by the C. J. Fischer Co., Detroit, Mich. At one time C. J. Fischer was connected with the Lavigne Co., and was interested in the production of the small car by that concern last winter. Mr. Fischer is now head of the C. J. Fischer Co., and the new Fischer car is made in several body styles ranging from $595 to $845.



Side view of Fischer touring model with one-man top

The company expects to produce from 5,000 to 10,000 cars the first year. It is now negotiating for plants and expects to make deliveries by August 20.

The Fischer is a small car with a block motor 2 3-4 by 4. A three-speed selective gearbox is a unit with the motor. Shaft drive construction with a semi-floating rear axle are used. The wheelbase is 104 inches and the tread is the standard 56 inches.

The body styles are: Model A speedster $595, tires 30 by 3; Model B Two-passenger car $595, tires 30 by 3; Model C cabriolet two-passengers, $645, tires 30 by 3; Model D, four-passenger touring, $645, tires 31 by 3.5; and Model E four-passenger sedan, $845, tires 31 by 3.5.

The designs of all the body styles are conventional streamline effects. The speedster is really a racing design with large hood in the cowl and very low seat, the effect being accentuated by semi-elliptic springs mounted below the axles. It does not carry fenders.

The two-passenger roadster is also a low-hung type but uses three-quarter elliptic springs and has a high-sided body with all equipments.

Wire Wheels Standard on Speedster

The standard equipment on all models is artillery wood wheels with the single exception of the speedster, but a set of five Houk wire wheels can be secured for $30 extra. The speedster carries these as regular equipment. Where wood wheels are used demountable rims are fitted.

All models use a V-shaped radiator designed to be proportionate to the chassis size, and rounding the radiator at the top takes away the abrupt line at the front. Crowned fenders are used.

The equipment of all models includes an electric cranking and generator system, speedometer, windshield, top, etc.

The motor used is a standard Perkins type made by the Massnick-Phipps Co., Detroit. It has a bore of 2 3-4 inches and a stroke of 4 inches, giving a rating of 12.10. The motor readily turns up 15 horsepower. The power plant is three point.

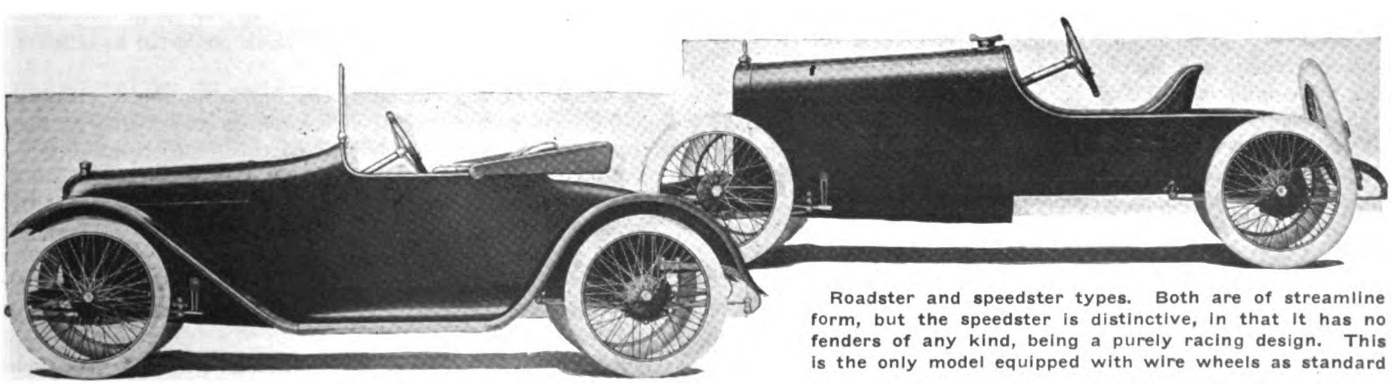
The cylinders are block cast and are L-head with the valves on the left and inclosed. The crankcase is of the barrel type, which construction is much used on small motors due to the greater rigidity which it gives to the crankshaft bearings and to the better machining. Inspection of the bearings is made possible through the plate at the bottom which also forms the reservoir for the oil.

An unusual feature is the manifolding on the left side. The intake and exhaust are really cast in one piece, the passages to the various openings and to carbureter and exhaust pipe being cored within the casting. The exhaust passes above the intake and there is an opening to each cylinder. Below this there are the two passages to the intake ports, a short pipe from the carbureter connecting to this casting at the center. The exhaust pipe joins the combination manifold at the rear. This construction has the advantage of assisting gas vaporization and should make for a better atomized mixture.

The oiling is done by a plunger pump and splash from the ends of the connecting rods dipping into the individual oil troughs.

Cooling is by thermo-syphon and ignition by the Atwater-Kent distributer system.

The motor gives its power to the rear through either a cone or multiple disk clutch and thence to a three speed selective sliding gearset. Thence it is passed on by a 3 1-2 per cent. nickel steel drive shaft which is equipped with a Spicer universal joint. The rear axle is semi-floating of the bevel gear type and its axle shafts are carried on Hyatt bearings, while the pinion shaft is mounted on double-row ball bearings.



Roadster and speedster types. Both are of streamline form, but the speedster is distinctive, in that it has no fenders of any kind, being a purely racing design. This is the only model equipped with wire wheels as standard

Prophesies Internal-Combustion Motored Car Simpler than Electric

The Automobile Engineers' Forum

Thinks 40 Miles an Hour on City Streets Set Aside for Rapid Traffic Is Mild Expectation for Future—Automobile No Longer a Fashionable Fad But a Necessity

COLUMBUS, O.—Editor THE AUTOMOBILE—There are a number of points in the recent address of Dr. C. P. Steinmetz on electric vehicles, reported in your issue for June 11, which would be interesting subjects for further discussion in your columns.

That the automobile is to a large extent following the history of the bicycle is a statement which few will deny, but it may indeed be doubted whether the decadence of the fashionable amusement of motoring will relegate the gasoline vehicle to the very limited field of usefulness prescribed by the noted electrician.

As to big, unwieldy engines, their day is even now almost over—their doom was sealed at Indianapolis when a car of only 183 cubic inches displacement made its wonderful showing.

The future competitor of the low-priced electric will be a gasoline vehicle with no excess power or weight, and with parts selected with a view to maximum simplicity and reliability. Thus developed, its advantage over a vehicle depending on any present form of storage battery will be considerable.

40 m.p.h. on Special Streets

It must first be understood that there is nothing fixed or final about present limits of speed in ordinary driving. The average speed of human transportation has been an ever-increasing variable ever since power was first harnessed. Present speed limits for safe driving are governed by mechanical reliability, road conditions, and (principally) by psychological state of both motorists and pedestrians. All of these factors will show great improvement in the future, and in a few years it may be possible to drive through a city at 40 m.p.h., perhaps on streets set apart for rapid travel, with safety fully as great as at 15 m.p.h. under present conditions. The business man, or workingman, may then have a cozy country home 10 miles from his work, and reach it in no more time than the city man now spends turning corners and dodging pedestrians in the city.

Certainly the congestion of city residence must be relieved in the future in some such manner as this; and the storage-battery vehicle will not do it. Central-station battery charging with daily delivery of car will be prohibited by distance and high labor cost; private rectifier plants involve cost, attention, and usually poor care of batteries. As to weather reliability, the internal-combustion vehicle is steadily gaining on the storage-battery type, and may soon greatly exceed it. And for every-day transportation speed will be as essential to the future vehicle as it is to the present railway train.

Control Can Be Made Simple

As to control, it can be made simple if desired. Manual spark control is no longer necessary for satisfactory operation and economy; gear-changing can be done mechanically or electrically if desired, and need hardly be more difficult than using the controller of the electric.

The bicycle is limited in its sphere of usefulness by its low speed and carrying capacity, and by the disinclination of man for work. But the light internal-combustion vehicle has possibilities of time-saving and cheap convenience which cannot be impaired by the passing of a fashionable sport.—H. K. RANDALL, M. E. in E. E.

Thinks Present Agitation Against Headlight Glare is Overdone

BOSTON, MASS.—Editor THE AUTOMOBILE—One of our engineers, who is now in England, has kept in close touch with the various tests of devices and lamps constructed with a view toward eliminating the glare of headlights, but according to reports which we receive from this gentleman, nothing has yet been evolved to satisfactorily reduce the glare without impairing volume of illumination.

We have experimented with so-called non-blinding glass; we have tried a partial eclipse with celluloid, glass, etc., in order to bring the ray below the eye level, but while we have been successful in eliminating undue brilliancy, we have at the same time been obliged to minimize the power of the lamps.

To be quite frank, we believe that this present agitation is being overdone, and that the effect of approaching headlights at night is not so serious as some people seem to believe. As a matter of fact, the drivers of approaching cars are but momentarily within the glare of the beam and immediately pass therefrom.

No Way to Solve the Problem

So far as we can determine, there is no way in which this problem can be solved. As soon as the dazzling effect is minimized the illumination is reduced in proportion, and we believe that the brightly lighted highway is of vastly more importance to the automobile driver than the occasional meeting with a car equipped with powerful headlights, coming in the opposite direction.

We are selling a great many headlights equipped with our dimming attachment. This is in reality two bulbs of different candlepower within one of our standard headlights.

In the center is the regulation bulb, and when the lighting switch is turned all on or head and rear on this bulb is illuminated and the small 4-candlepower bulb at top of reflector remains unlighted.

When the operator desires to dim headlights the switch is turned side and rear on. This lights the small bulb and the large bulb becomes inactive.

We have had submitted to us various attachments, such as swivel shields of blue glass, patches to be placed immediately in front of the steering column; and now we hear of a pair of goggles recently invented by a motorist in Massachusetts whereby the approaching glare is entirely eliminated. However, none of these accessories seem to be practicable. It is quite possible that there is a genius somewhere who will some day evolve a non-blinding headlight which will possess all the qualities of the regulation headlight, but the perfection of such a device is evidently in the distant future.

A discussion along these lines should result in an interchange of ideas and opinions which may bear fruit in the way of a glareless headlight. We shall watch future pages of THE AUTOMOBILE with a great deal of interest, and we sincerely hope that you may be able in this way to solve the problem.—GRAY & DAVIS, INC.

Supply Dimmer Switch for Headlights Under Protest

BRIDGEPORT, CONN.—Editor THE AUTOMOBILE—We have tested every known method of cutting down the glare of electric headlights for automobiles, cyclecars and motorcycles. We are supplying the electric lighting equipment for a large number of manufacturers of cyclecars and small automobiles.

We do not advocate the use of the dimmer switch but we are forced to supply this because our trade demands this type of device.

In the first place, when the searchlight is provided with two electric bulbs, it provides an insurance to the auto driver and guarantees to him having at least two bulbs in good condition at all times. Two headlights each equipped with two bulbs provide four bulbs and leave a sufficient margin of safety.

Dual Bulb System Best

The small pilot light can be a 1, 2, 4 or 6 candlepower bulb to provide the necessary and essential amount of illumination for driving in any part of the country. If the automobile owner does 95 per cent. of his driving in a well-lit city, a 1 candlepower pilot light is of sufficient brilliancy. If the owner resides in the suburbs, a 2 or 4 candlepower is sufficient. If he lives in the country, the 6 candlepower will supply all the light required for driving a short distance until he can again use the searchlights. The writer has tested this dual bulb system so thoroughly that he is convinced that he is wasting his time to consider any other system because the results are sure, satisfactory, comply with the law and provide a sufficient supply of light for driving at the same time cutting down the dazzling glare that is so annoying to other drivers and to horsemen.—E. A. HAWTHORNE, President Hawthorne Mfg. Co., Inc.

Thinks Practical Ideal Car Possible by Correct Design

WATERLOO, IA.—Editor THE AUTOMOBILE—If you were in the manufacturing business sitting in judgment of the ideal car designed by your engineer you would know something of the vagaries and the chimera of the man of theory.

It is only by long experience and putting to practical use theories, that facts are established and frequently theories are demolished.

It is related that Prof. Agassiz, a great naturalist, on his way into the Maine woods to study fish was being regaled with fish stories by his guide who told him that speckled trout were frequently found where they were going, that weighed 7 or 8 pounds. The great naturalist told the ignorant guide that this was impossible, that speckled trout couldn't grow to that size. The naturalist in telling the story, said that he on the next day caught a speckled trout that weighed over 9 pounds. Thus was a lifetime of theory exploded by a single fact.

The theoretical ideal car costs a little more to build and turns out to be no better than the actual one.

Did you know that the great inventions and discoveries of the age are largely made by tenderfeet in the profession to which they belong, that is to say, men who are uneducated in the business and have no more sense than to depart from the theory and try out by experiment and thus learn.

Duesenberg Is an Example

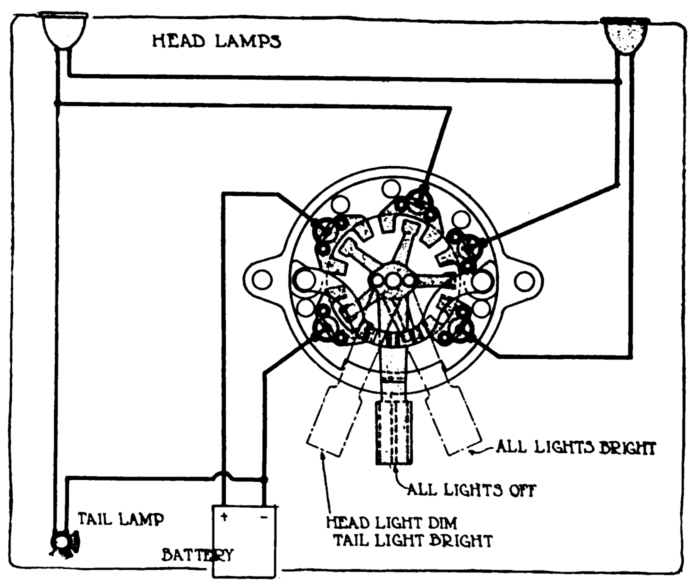
To illustrate the point I am trying to make on a theoretical ideal car, in 1905 Fred Duesenberg, educated in the common schools of Iowa without so-called technical education, obtained in schools and colleges, built his first two-cylinder motor for an automobile, following out a design he had used in producing a motorcycle. By common consent that motor proved to be the greatest two-cylinder motor ever put into an automobile.

Mr. Duesenberg built a single-cylinder motor so arranged that he could produce any degree on his camshaft by threading his shift and by an ingenious device could raise or lower the cylinder and thus increase or decrease the compression and could also set the cylinder off center on one side, then by careful experiment under a brake test he determined the proper degree to set his cams, the proper compression and the proper offset.

The Real Ideal Car

The information he gained there, he applied to the two-cylinder motor and has also applied it to the motor that we are now building into cars and the cars with this motor in them are meeting with the most enthusiastic reception by the public.

At the same time our agents, some who have been with us for the last 4 years and furnished us money to run on, still have their ideal car. Their ideal car doesn't consist of machinery parts, but simply of the painting, upholstering, body lines, top, etc. They say that it seems at times as though you could sell anything in a chassis that had a body and finish that appealed to the customer, and at the same time we are continuing to build an automobile to run and sell and stay sold.—E. R. MASON.



Wiring diagram showing the method of control used for dimming headlights by the Hawthorne Mfg. Co.

Gearset of Geometrical Design Is Best

Makes Gearshifting Easier Than the Arithmetical Design with Less Danger of Clashing—More Power on Third Speed of Four-Speed Type

By W. C. MARSHALL

Part I

A CHANGE speed gearbox employing a geometric ratio between first, second, third and fourth speeds, is a better type of gearset for an automobile than an arithmetical design in which an arithmetical ratio is maintained between the different successive gear ratios.

The geometrical type of gearset is better because with it gearshifting is easier, and there is less danger of clashing. Further, the geometrical design of gearbox gives more power on third speed in a gearbox with four speeds forward.

A geometrical gearset, say with four forward speeds, is one in which the increase in ratio is in the form of a geometrical progression, as, 1, 2, 4, 8. To explain: Your gear ratio is 8 to 1 on low, is 4 to 1 on second speed, is 2 to 1 on third, and is 1 to 1 on fourth or direct. In a geometrical progression, the ratios are multiples of 1 or 2 or 3 of the preceding number, thus in the example, 2 is double of 1, and 4 is double of 2, and 8 is double of 4. Another geometrical ratio might be 1, 3, 6, and 12. Still another 1, 3, 9, and 27.

The Arithmetical Gear Ratios

On the other hand, an arithmetical progression is one in which the increase in ratio is accomplished by even steps. Thus, in your four-speed gearset, the four gear ratios may be: 1, 5, 9 and 13, that is, 13 to 1 on low, 9 to 1 on second, 5 to 1 on third, and 1 to 1 on direct. You will note that 4 has been added in the arithmetical ratio. We could have another arithmetical ratio in which 3 might be added, and it would be 1, 4, 7 and 10.

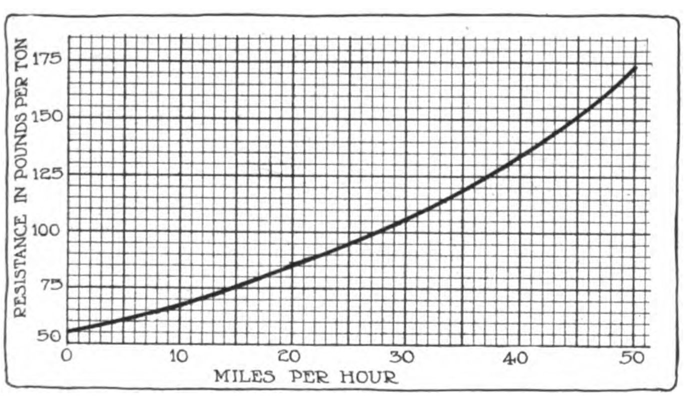


Fig. 2—This diagram is intended to show that the car resistance in pounds per ton of car weight is greater at high speeds in miles per hour than at low speeds. For example: At 25 miles per hour the car resistance is 95 pounds per ton weight of car, whereas when the car is traveling 50 miles per hour the car resistance has risen to 170 pounds per ton of car weight. Now, Fig. 1 shows a power curve which falls as the speed of the motor is increased in r.p.m., whereas Fig. 2 shows a curve of car resistance which rises as the speed of the car in miles per hour rises. Consequently, the gearbox is the necessary go-between to bridge the gap between the diverging conditions in Figs. 1 and 2; in a word, the gearbox is the means whereby we furnish the power to overcome the higher resistance of the car from the motor at low speeds

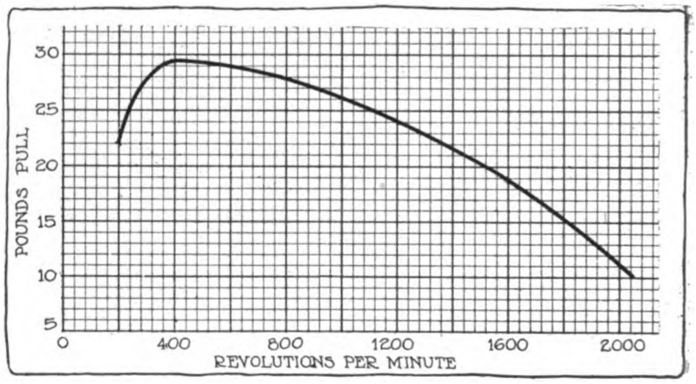

Fig. 1—This diagram shows why a gearset is necessary in a car. The curve shows that the power from the motor is greater at 400 r.p.m. than at 1,800 r.p.m. so far as actual pull is concerned, and this is because the pressure in the cylinder is greater, which is the case because a greater charge of gas enters the cylinder at 400 r.p.m. than at 1,800 r.p.m.

Here then we have what is meant by a gearset employing geometric ratios for the different forward speed changes, and also what is meant by a gearset employing arithmetical ratios for its different formed speeds. The question to be proven in this article is that the set with a geometrical ratio is preferable for different reasons than the gearset with arithmetical ratios. The following paragraphs tell first why it is easier to shift gears using a geometric type of gearset, and also why there are more equal changes in motor speed with the geometric type than with the arithmetical.

In any gearset the desired object to be attained is that there is the same change in motor speed between first and second as when shifting between second and third or shifting from third into fourth. In the geometric gearset these steps are uniform, whereas in the arithmetical gearset they are not, and to this are ascribed the reasons for greater difficulty in gear-shifting with the arithmetical gearset.

Why Use a Gearset?

First we must ask ourselves why we need a gearset. Here is the answer: The modern automobile, which has an internal combustion engine for driving power, is, to a large extent, dependent on the range of power compassed by its motor. This is largely governed by the size of the motor. The motor develops its power not at a given number of crankshaft revolutions per minute, as a steam engine, but at varying revolutions.

If it could develop as much horsepower at few revolutions per minute as is possible at many revolutions per minute there would be less call for large motors and fewer speed changes in the gearbox.

The ordinary motor develops its maximum pressure on the piston (about 95 pounds per square inch) when the engine speed is about 800 revolutions per minute. If the speed increases the gaseous mixture has not sufficient time to enter and fill the cylinder, therefore the pressure becomes less and the turning power per revolution decreases.

One Reason for Gearset

The curve of average pressure in the cylinder has a form in general like that in Fig. 1. It is evident that a load cannot be carried by the engine at a low speed, therefore if an engine were directly coupled to the driving wheels of a motor car it would be impossible to start the car without outside assistance.

The average pressure on the piston multiplied by the radius of the crank equals the torque of the motor. If the torque is multiplied by the revolutions per minute and the length of the circle through which it moves, the product equals the foot-pounds of work performed by the motor in a minute. The horsepower exerted can be found by dividing these foot-pounds by the foot-pounds per horsepower, namely 33,000.

Horsepower can obviously be increased by increasing the revolutions per minute. As more horsepower is needed to start a motor car than to keep it in motion, except for high speeds, some means must be employed to enable the motor to run at high speed at a time when the car is running at slow speed. The curve of resistance of a car (on a level road) can be represented graphically as in Fig. 2.

Where the Gearbox Comes

As the torque curve is shown by Fig. 1 to be of little value before the engine reaches 400 revolutions per minute we must introduce some mechanism between the motor and the driving wheels which shall allow the engine to run at a high number of revolutions per minute while the road wheels are rotating slowly. The most common mechanism to-day is the gearbox in combination with the clutch.

Deciding on Gear Ratios

Let us consider the problems which determine the design of the gearbox. The motor design and brake test give an idea of the power available under the bonnet while the resistance of the car is the factor which determines what work must be done by the motor.

How shall we determine the intermediate gear ratios to enable the motor to properly overcome the variable resistance and yet not exceed its economical or workable speeds?

The ideal curve of tractive effort would appear substantially as shown in Fig. 3. The low-speed reduction in the

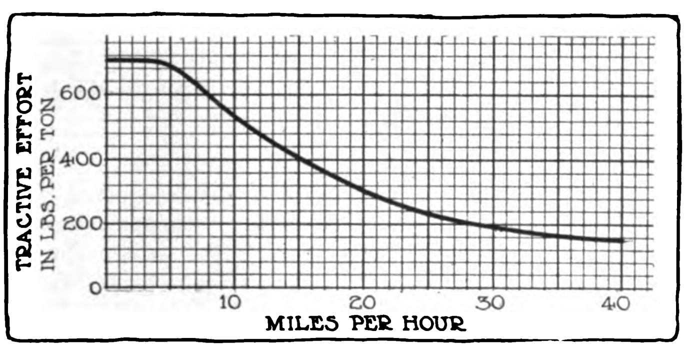

Fig. 3—This curve shows the power that can be exerted by the motor in propelling the car. For example: Fig. 1 shows the power the motor can give, and Fig. 3 shows the proportion of this power that can be applied to moving a car, the remainder of the power being lost in friction. Thus at 10 miles per hour the power exerted by the motor would be 500 pounds a ton in propelling the car, and at 30 miles per hour the power in propelling the car would be 200 pounds per ton, and at 40 miles per hour the power needed for propelling the car would be 150 pounds per ton of car weight. This is because the motor is working faster and its torque, or power curve, falls off

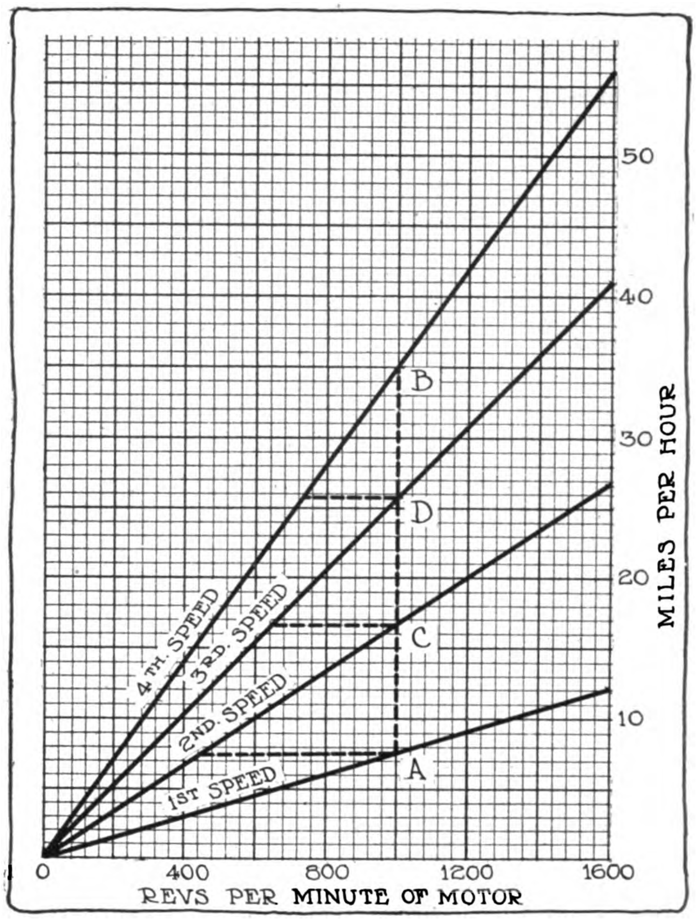

Fig. 4—This curve illustrates graphically how motor speeds must change when shifted. It is a diagram of an arithmetical gearset and shows by the three horizontal dotted lines the changes in speed when going from low to intermediate, from intermediate to third, and from third to fourth. These three dotted horizontal lines are not all of the same length; the bottom one, representing the change in speed of motor when going from low to intermediate, is much longer than the other two. This means, in other words, that there is much greater change in the motor speed when shifting from low to intermediate than from intermediate to third or third to fourth. This difference is not desirable, and the ideal gearset would have the same amount of change in motor speed between low and intermediate as between the other speeds

gearbox should be such as to overcome all the difficulties encountered en route, as well as to reserve enough motor power to accelerate the vehicle at starting. Air resistance can be neglected in first speed calculations because it is so small at moderate speeds.

Let W = weight of loaded vehicle,
t = coefficient of traction,
c = % grade of steepest hills one meets,
R = radius of driving wheels
and T_m = equal turning effort or torque of motor.

Then the resisting force of the vehicle will be

$$F_r = RW(t + c) \qquad (1)$$

If E = the efficiency at the rim of the power transmission mechanism and r the ratio of R.P.M. of the motor and wheels, the available power at the rim will be

$$F_d = rE\,T_m \qquad (2)$$

The force which can produce acceleration will be

$$f = \frac{F_d - F_r}{R} \qquad (3)$$

and the acceleration will be

$$j = \frac{fg}{W} \qquad (4)$$

Substituting in (3) the values of F_r, F_d and f obtained from equations (1), (2) and (4) we have

$$j = g\left(\frac{E\,T_m}{WR}\,r - (t + c)\right) \text{ and } r = \frac{WR}{E\,T_m}\left(\frac{j}{g} + (t + c)\right)$$

If we took $T_m = 184.4$ ft. lbs., $W = 3600$ lbs., $R = 1.46'$, $r = 18$ $(t + c) = 0.2$, $E = .65$

$$\text{then } j = 32.2\left(\frac{.65 \times 184.4 \times 18}{3600 \times 1.46} - 0.2\right) = 6.76 \text{ ft. per sec.}$$

The highest gear ought to permit the vehicle to advance on a moderate road on a level or perhaps up a gentle slope without forcing the driver to change his transmission gearing from high to a lower ratio because of the least difficulty. The highest speed then ought to be serviceable in the great majority of cases that occur. It is necessary, as experience shows, to avoid an exaggerated gear ratio which requires the hand constantly on the change speed lever and which, moreover, is rather a cause of retarding the mean speed than of accelerating it.

In the establishment of the highest speed gearing there is no need of considering the acceleration, but it is necessary to take account of the air resistance which is at its maximum.

Let t' = coefficient of traction,
c' = % of slope.
r_h = the gear ratio,
S = surface of vehicle presented to wind ahead.
V = speed hoped for.
C'_r = the resistant couple.
C_a = the available couple.

We have then

$$C'_r = W\,R\,(t' + c') + 0.0056\ RSV^2$$

and $C'_a = r_h\ E\ T'_m$.

Equating these two expressions, since the acceleration is neglected.

$$r_h = \frac{RW\,(t' + c') + .0056\ SV^2}{E\ T'_m}$$

The graphical illustration of the variation of speed changes can be shown by Fig. 4.

Adopt for the first speed ratio of gearing the ratio 14 as r.p.m. of motor to wheels. For 1000 r.p.m. this gives 7.4 miles per hour as the speed of the vehicle.

Erecting an ordinate at 1000 r.p.m. to meet the horizontal line of 7.4 miles speed gives us a point on the first speed line which can be drawn through the origin and this point.

The same calculation with a gear ratio of 3 gives a speed of 35 miles per hour.

(To Be Continued)

Recent Court Decisions—Defeats Trolley Co

By George F. Kaiser

NEW YORK Court holds in a recent case that, when a person comes out of his house to help his visitors into their automobile and, while standing between the car, which is pulled up close to the curb, and the trolley tracks, is injured by a trolley rapidly approaching, he may collect from the trolley company.

In this case a man was helping a woman into the front seat of an automobile and was standing between the trolley track and the machine, in a space about 3 foot wide. Before he came out into the street he had looked to see if any cars were approaching. He saw none, however, and heard no signal and was unaware of the fact that a trolley was coming until it struck him. The Court said that, the fact that he was standing there from one-half minute to a minute while opening the door of the automobile, did not necessarily mean that he was negligent but that was a question for the jury.—*Breese vs. Nassau Electric R. C.*, 147 *N. Y. Sup.* (*New York*) 416.

Dealer Liable While Demonstrating

Oregon case decided against dealer who was demonstrating a car and teaching a person, who had made a contract to buy, how to run the car.

A person while walking on the street was run down and injured by an automobile which was driven by a salesman employed by a dealer. The car at the time the accident occurred was being driven by a man who had contracted to buy it. The salesman had just given him a demonstration and at that time was acting as his instructor, showing him how to operate the car. The injured person brought suit for $40,866, and sued both the dealer and the buyer. The jury first returned a verdict of $2,750 against the buyer and $5,250 against the dealer. The court refused to accept this verdict, however, telling them that it could not split up the damages that way, holding one party for one-third of the damages and the other for two-thirds. The jury thereupon retired again and on returning gave a verdict against the dealer for the entire amount. The dealer appealed, but the Court held that as it was understood that the buyer was to be taught to run the car by the dealer, and the person in charge of the car, though not actually operating it at the time of the accident, was one of the dealer's salesmen, the verdict of the jury should not be disturbed and held that the judgment for $8,000 against the dealer was right and proper. —*Holmboe v. Morgan, et al.*, 138 *Pac.* (*Oregon*) 1084.

Collects from Bus Driver

A radiator of an automobile which has been injured in a collision may be brought into Court and introduced as evidence, providing it is shown that it is in the same condition when brought into Court as it was immediately after the accident.

In a recent Iowa case, suit was started for damages on the claim that a bus driver had negligently run the tongue of the bus through the radiator of an automobile and bent the lamps, lamp brackets, fenders, hood and the fan of the car; $117.95 damages were asked. The jury gave the automobile owner judgment for $75 when the radiator which had been damaged was brought into Court and introduced as evidence. The owner of the bus objected to the radiator being brought in, but the Court held that it was properly admitted.—*Neel v. Smith*, 147 *N. W.* (*Iowa*) 183.

Motorist Fails of Recovery

Washington Court says that when an automobile approaches a street car crossing its driver must make a reasonable use of his senses for his own safety and he is negligent if he is not on the lookout for cars at a point where he can determine if he can get across safely and if an automobilist approaching a crossing takes his last look for cars when 150 feet away, the Court further declared, he is guilty of contributory negligence.

In this case a motorist sued for personal injuries caused in a collision with a street car at a crossing. The automobile was found to have approached the street car at a speed of 20 miles per hour, with its side curtains up and the Court held accordingly that the motorist was guilty of contributory negligence and dismissed his case against the railroad.—*Bowden vs. Walla Walla Valley R. R. Co.* 140 *Pacific* (*Washington*) 549.

Plug Location Has Little Effect

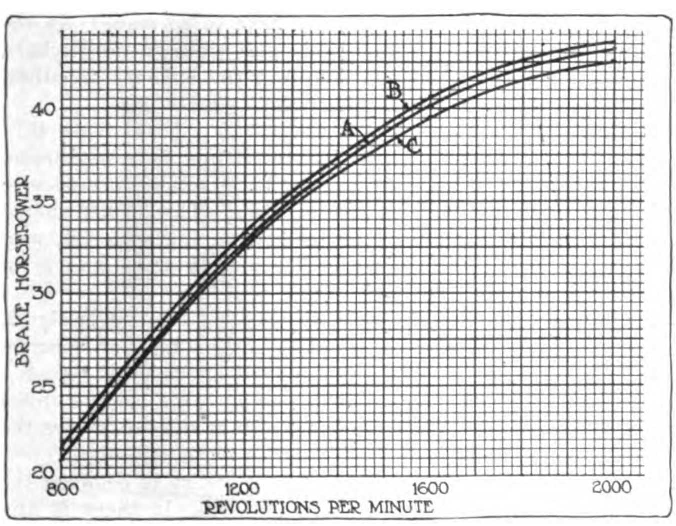
Difference Between Power Curves Produced with One and Two-Point Ignition Also Slight According to Latest Experiment

THERE have been endless experiments to determine the difference made in the power produced by a motor with one or two sparks or with the plug located in different parts of the cylinder. These experiments are always of interest because they vitally effect the user of the car by determining for him whether or not it is possible to secure a greater amount of power out of the same size motor. The latest experiment in this line shows a very little difference between the power produced when the plugs are located over the intake or exhaust valves and also but slight change when a two point instead of a single point ignition system is used. The experiments have been performed by C. F. Dendy Marshall and are reported in *The Autocar*. The report follows:

"It is, I think, a foregone conclusion that, given a good spark, neither duplicating it nor changing its position, can give more than quite a small increase of power. I recently suggested, and took part in, a trial which throws some light on both these points. A six-cylinder engine was put through three sets of brake tests under precisely the same conditions —(A) with single sparking plugs over the inlet valves, (B) with double plugs in series, one over each valve, and (C) with single plugs over the exhaust valves. As the engine was a new one, and had not been brought up to its full power, it would not be fair to mention the name and dimensions, but, of course, the comparative value of the tests remains.

Compression Space Kept Constant

"There were two plugs in each cylinder all through, in order that the compression space should not be varied, one set being disconnected during the first and third series of tests. The extra plugs were of the double pole variety. This is necessary, because the ordinary plug discharges to the cylinder, so in order to obtain two sparks the current must enter and leave by the first plug without being "grounded," passing on to the next one. This in effect forms the old gap system, which was thought a good deal of ten or twelve years ago, only in this case the gap is inside the cylinder instead of outside.



Three curves of brake horsepower under different spark plug conditions: A, with single plug over the intake; B, with double plugs in series, one over each valve; C, with single plugs over the exhaust valves

"The following are the figures obtained, each one being the average of four observations taken during the course of a minute. No significance need be attached to the fact of the first one in Test 3 being just above the corresponding figure of Test 1, as the difference is so small, and was probably either due to errors of observation, or to a slight irregularity in the running of the engine.

Revs. per minute	800	1,200	1,600	2,000
B.H.P. Test A	20.9	32.8	40.2	43.5
B.H.P. Test B	21.4	33.3	40.5	43.7
B.H.P. Test C	21	32.6	39.4	42.6
Approximate percentage of difference of power.				
Test B over A	2½	1½	¾	½
Test A over C		⅓	2	2¼

Two Plugs Are Unnecessary

"The results of the three sets of tests are plotted in the accompanying curves. On the whole, the conclusion seems to be that two plugs are hardly worth having. In the engine under test the advantage of double ignition is more marked at slow speeds, being quite negligible when the engine is running hard. On the other hand, the position of a single plug becomes of greater importance as the speed increases.

"The engine I experimented with was of the fashionable type, with all the valves on one side. In "The Gas, Petrol, and Oil Engine," by D. K. Clerk and G. A. Burls (vol. ii.), a similar test with a T-headed engine is mentioned on page 337, which was carried out by Professor Watson, the results being:

R.P.M. of engine	1,100	1,600
H.P. single ignition	18.4	26
H.P. double ignition	20.8	29.2
Difference	2.4 (12%)	3.2 (10%)

"In this case the advantage is increased with the speed, though not the percentage of improvement. It seems that the double plug arrangement has much more effect when the valves are on opposite sides than when they are on the same, owing probably to the two points of ignition being farther apart, and perhaps partly to the fact that the charge is symmetrically fired."

Los Angeles Has Kelly-Springfield Buses

The bus lines which are to be operated by the Pacific Motor Coach Co., Los Angeles, Cal. between Los Angeles and various nearby cities will use, 3.5-ton trucks, made by the Kelly-Springfield Motor Truck Co., Springfield, O., and fitted with bodies built by the St. Louis Car Co., St. Louis, Mo.

The maximum speed will be between 18 and 20 miles per hour, and the buses have a seating capacity of 54 passengers, sixteen being housed in the closed compartment of the lower deck, eight in the open compartment, and thirty on the upper deck.

Chassis Is Stock 3.5 Ton

The chassis used is a stock 3.5-ton design fitted with 6-inch dual rear tires and specially heavy axles. The motor is a four-cylinder water-cooled type, suspended on three points. The cylinders are T-head, cast in pairs and the bore and stroke is 4.5 by 6.5 inches. Speed changes are effected through a three-speed sliding gearset.

It is also expected that the Pacific Coach Co. will have the concession for motor transportation within the ground of the Panama-Pacific Exposition.

The Rostrum

Two-Cycle More Flexible When Skilfully Adjusted

EDITOR THE AUTOMOBILE:—Seeing by the recent letters in THE AUTOMOBILE that many of the readers are friendly to the two-stroke cycle motor, I have had revived in me my old-time two-cycle enthusiasm which I had when I used to sell Elmore valveless cars. Let it be said, in all truth, that while many cars cost more and looked better, I have yet to see the first four-cycle car excel in performance or in fuel economy.

The last 50 horsepower car turned out by the factory is running in Tampa today and is giving its owner 13 miles to the gallon of gasoline after having it fitted with special equipment. This car is a 1912 model.

To the man who has had a wide range of experience in the several types of automobile motors, the assertion often made by well-meaning four-cycle advocates, that the four-cycle is more flexible than the two-cycle, is really amusing, but is true enough in the hands of a four-cycle driver.

It has been my experience that the average good four-cycle driver is apt to make a poor two-cycle driver—it is a good deal like learning the two-step before the waltz.

To get flexibility out of a two-cycle one has to be a good carbureter adjuster, changing the mixture as the load and speed varies. The use of a well-trained ear helps wonderfully; I think the skillful operation required is the biggest factor that has worked to keep the two-cycle in the background as far as automobile service is concerned.

In France the two-cycle is making progress. Especially is this true of the four-cylinder Koechlin, which has a bore and stroke of 3.3 by 5.9 inches, producing a piston speed of 3000 feet per minute and developing 110 horsepower. This motor has no crank-case compression; in fact, I do not know of any of the best motors that do have it. With Europe developing the two-cycle it looks as though it may yet come to the front.

Tampa, Fla. L. C. HANNA.

Planning One-Story Garage

Editor THE AUTOMOBILE:—We are planning to build a one-story garage of brick, 50 by 150 feet, and we would like to receive suggestions from you as to the general layout and inside finishing for the stock room, show room and office.

Grafton, W. Va. B. M.

—In laying out the garage you should put the show room and offices at the front and the benches and machine tools across the back of the structure. The rest of the space should be devoted to storage. A plan is shown in Fig. 1.

How much space should be given to the show room and the supply store depends entirely on how many models you plan to carry and how great a stock of accessories you intend to display.

In general a 20-foot strip across the front of the building, with a space at one side for the entrance of cars to the garage, should be large enough. The offices should be placed next to the entrance, and at the other side of the structure put the supply store, with the space in between for the display of cars.

The office should be placed next to the entrance so that the same clerk can check the cars as they go in and out that attends to the office.

In the large central space the cars can be displayed to best advantage. The space devoted to accessories should be separated from the show room by a railing, and the office should be similarly partitioned off.

The finish can be almost anything desired. For instance, you might use a good hardwood floor, such as maple, oak or parquet. The trim may be any of the woods used in house construction, such as oak, chestnut, cypress, and the walls can be papered, painted or paneled, according to your taste and the amount of money you have at your disposal.

The repair of cars should be done at the rear of the building, as the best light will be here, and also this arrangement allows an unbroken space in between for car storage. Place the machine tools at one side, back of the benches, and on the other side arrange two or three pits. The roof should have plenty of skylights, and the walls of the garage should be strong enough to allow the addition of a second story at some later date.

Wants Quieter Valve Action

Editor THE AUTOMOBILE:—1—I would like to put a quieter valve action into my 1911 car. It has the square head or mushroom type of valve now. Could the roller tappet type of the Packard 18 be applied? If so, could I use the regular Packard cams or would a new set have to be made? In the Cadillac the valves are all on same side, while in the Packard the inlet valves are on one side and the exhaust on other. Would this make any extra difficulty?

Plattsburg, N. Y. S. D. B.

—1—We would not advise you to change from mushroom to roller followers, as there is very little actual difference in the noise produced by these two designs. The former should be quiet enough to satisfy the most exacting motorist, providing the valve mechanism is not unduly worn and is in proper adjustment.

The side thrust of the cam on the follower face, Fig. 2, as the valve mechanism is lifted, produces unequal wear on the valve guide. In time this wear is sufficient to cause a noticeable amount of noise, due to the push rod being slapped up against one side of the guide every time the cam moves the mechanism. The remedy is to put in new valve guides.

Another place that noise frequently occurs is between the end of the valve stem and the push rod. If there is any great amount of space between these two members a clicking noise will be produced. This can be largely eliminated by adjusting the nuts on the top of the push rod. A piece of carbon on the valve seat will also cause a valve to be noisy.

Another cause of noisy valves, that has been suggested, is produced by the sticking of the valves.

However, if you decide to attempt to make the change to roller cam followers you will not be able to adapt Packard cams but will have to make a special design. It is doubtful also whether even then will it be possible to use rollers because of lack of room.

Wants Hunting Body with Bed

Editor THE AUTOMOBILE:—Is there a car body made for hunting? One so arranged that the back of front seat may be turned back against the rear seat of the car, forming a bed?

Bakersfield, Cal. THOMAS SCOTT.

Such a body can probably be obtained from the Spaulding Mfg. Co., Grinnel, Ia., maker of the Spaulding car. This concern fits the body illustrated in Fig. 3. The back of the front seat folds down and exactly fills the space between the front and rear seats. The back is held in position by two knurled head bolts. This equipment may be supplemented by a reading lamp and an air mattress, which is inflated by the power tire pump.

Another design is that shown in Fig. 4. This bed is made of heavy canvas, with a hem at each end, through which stretcher bars run. To the ends of these bars are fastened the front and rear supports, which are secured to their respective springs by means of ropes. When not in use the bed is rolled around the stretcher bars and made into a handy package.

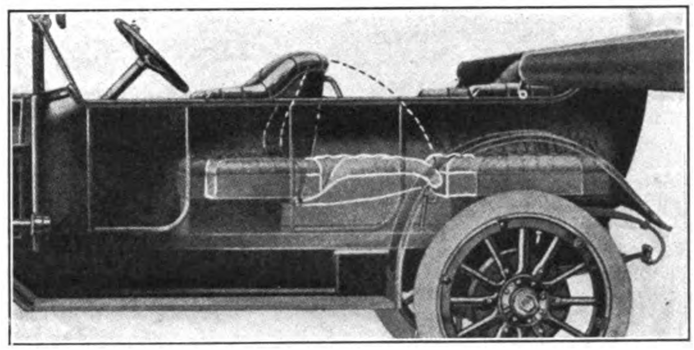

Fig. 3—Spaulding car that can be used for a bed

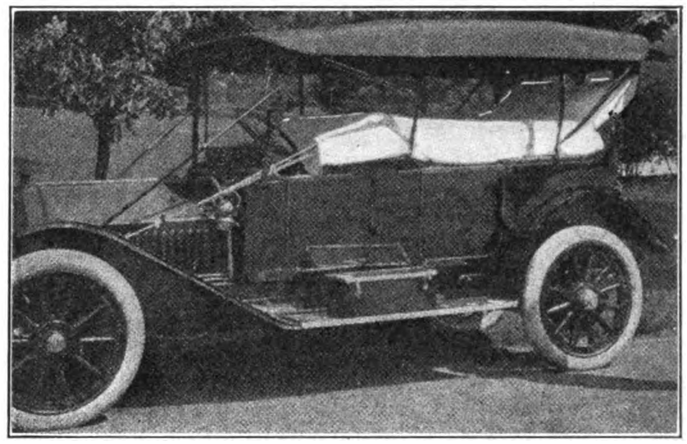

Fig. 4—Bed that is suspended over seats

Two, Four and Six-Cycle Motors

Editor THE AUTOMOBILE:—1—Please explain in next issue of THE AUTOMOBILE the proper way and easiest way to time a two-cycle, a four-cycle and a six-cycle motor.

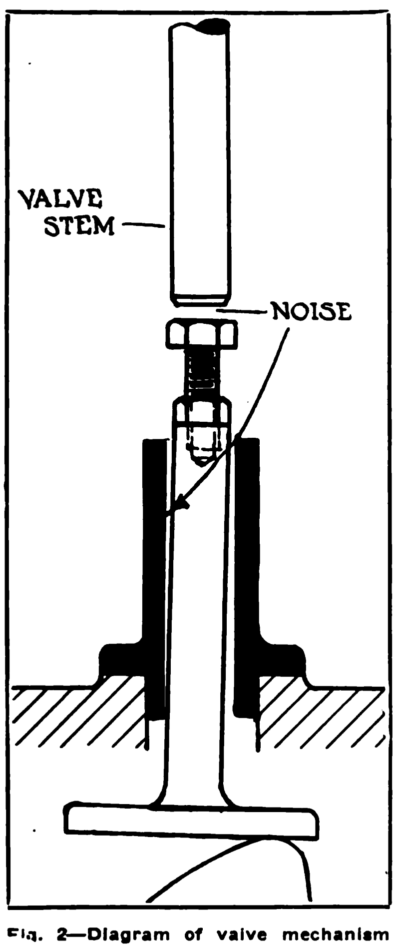

Fig. 2—Diagram of valve mechanism showing where noise occurs

2—Explain the different ways they fire and the difference it makes in timing the valves.

3—Give sketch and explain how to adjust a carbureter, especially the Schebler and Rayfield and a few more of the standards.

H. A.

Anniston, Ala.

—1—From the way you have asked these questions it is evident that you have not a correct understanding of the word "cycle" and that you have confused it with the number of cylinders a motor has. A cycle is the occurrence of a series of events at regular intervals. You might consider that the seasons, Spring, Summer, Fall and Winter form a yearly cycle.

In the same way gasoline motors are described as two-stroke cycle, four-stroke cycle or six-stroke cycle, depending on whether it takes two, four or six strokes of the piston to perform the complete set of functions necessary to produce an explosion. Thus in a two-stroke cycle, or a two-cycle motor, as it is more commonly known, the gas is forced into the cylinder when the piston is at the bottom of the stroke, is compressed as the piston moves upward and is ignited when the piston reaches the top of the stroke. Then on the downstroke the explosion occurs. When the piston reaches the lower end of the stroke the exhaust port is uncovered and the burnt gases escape.

In the four-cycle motor, on the first stroke the piston moves out and sucks in a charge of mixture, then on the second stroke the piston moves back again and compresses this charge. At the end of this stroke ignition occurs, and then as the piston moves out on its third stroke the gases expand. On the fourth the piston moves in again and forces the burnt gases out into the exhaust pipe.

Six-cycle motors are rare and have never been brought beyond the experimental stage. One that was suggested a few years ago had the following cycle, beginning with the explosion stroke: With the piston at upper dead center, at the end of the compression stroke, a small pump injected the correct quantity of fuel, and combustion took place. Following this there was a long expansion stroke, and then the exhaust stroke occurred. On the third stroke a charge of cold, clean air was sucked into the cylinder and was exhausted on the fourth stroke. More cold air was drawn in on the fifth stroke, while on the sixth compression of this air occurred. It will be noted that during three of the strokes, or one-half of the time, the cylinder was filled with cool air, and it was planned to use this means to cool the motor, no exterior ribs or any other influence being employed.

2—The ordinary two-cycle motor does not need to be timed, as the ports are automatically uncovered by the piston.

The operation of the two-cycle motor will be made clear by referring to Fig. 5. The gas is first drawn into the crankcase and then it is transferred under a pressure of 2 or 3 pounds to the combustion chamber. The left illustra-

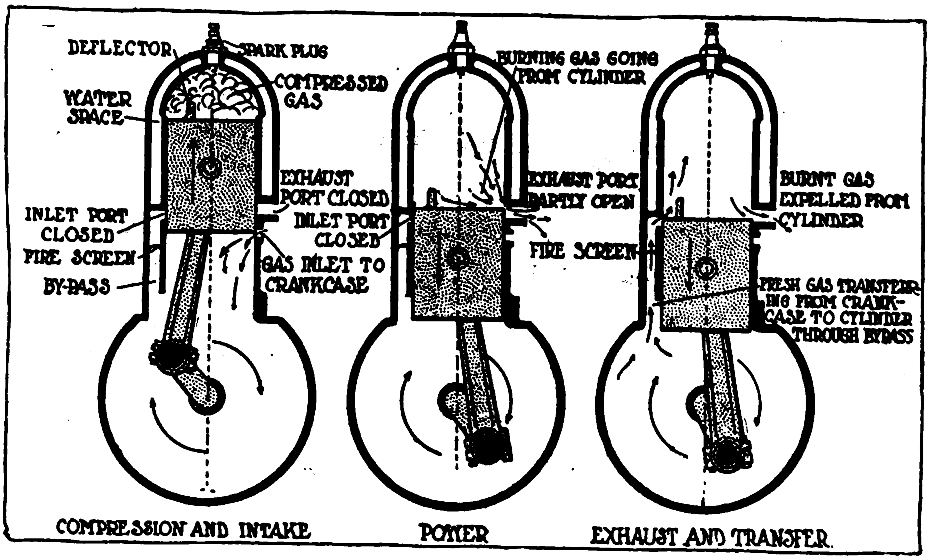

Fig. 5—Diagram showing operation of two-cycle motor

tion shows the piston nearing top dead center. The gas in the combustion chamber is being compressed and the upward movement of the piston has just uncovered the gas inlet port to the crankcase. At the moment that this port is opened the pressure in the crankcase is slightly lower than atmosphere, because the piston has moved upwards and thus increased the volume of the crankcase chamber, the increase of volume being accompanied with a reduction in pressure, since the quantity of the gas in the chamber remains constant while this is occurring.

The slightly lower pressure in the crankcase when the port is opened causes an inrush of gas from the carbureter.

When the piston reaches top dead center the spark ignites the gas and the piston is driven out on its expansion stroke. As it nears the lower end of its travel, as shown by the center diagram, the exhaust port is uncovered and the burned gases flow out. This downward movement of the piston also compresses the gas in the crankcase, so that when the inlet port into the cylinder is uncovered, shortly after the exhaust port, a fresh charge of gas is transferred to the combustion chamber. This is illustrated at the right.

It will be noted that there is a baffle plate on the top of the piston, which deflects the gas upward to the top of the cylinder so that the entering gas flows up one side of the cylinder and down the other. This action helps force any exhaust gas, that remains, out. A fine wire screen is placed in the by-pass to prevent a back fire from exploding the gas in the crankcase.

Timing of Four-Cycle Varies

2—Since there are no valves in the ordinary two-cycle motor, there is no timing to be done when the motor is put together, it merely being necessary to attach the pistons, connecting-rods and to put on the cylinders. The times of port openings and the length of opening can be varied to a certain extent by varying the width of the ports. For instance, referring to Fig. 5, it will be readily seen that if the exhaust port is made .75 inch wide the port will be opened sooner by the downward movement of the piston than if the port width is .5 inch.

The method used in timing a four-cycle motor all depends on conditions, although the object in any case is to so set the camshaft, which is positively driven from the crankshaft, that the valves will be opened and closed at the proper moments with reference to the positions of the pistons, and the only time you should have to do this is after taking the motor apart.

As a rule there is a mark on one of the teeth of the camshaft gear and another on the crankshaft driving gear, and if these two gears are set so that the two marks come together the motor will be correctly timed, providing the gears are properly attached to their respective shafts.

If there are no such marks, or if their correctness is to be tested, then the camshafts should be set so that the valves will open to correspond with the marks on the flywheel. Suppose, for example, that the motor is a T-head design with camshafts on opposite sides, one for the inlet and the other for the exhaust valves. Then there will be marks on the flywheel for the opening of the intake valves and others for the opening of the exhaust valves.

It is only necessary, however, to time one cylinder. If the intake and exhaust valves for cylinder No. 1 are correctly set, the timing of the other cylinders will be correct, because the camshaft moves as a unit.

Therefore, turn the motor over until the mark for the opening of the intake valve on this cylinder, Fig. 6, is at the top and then mesh the camshaft with the crankshaft gear in such a way that the intake cam will be holding the push rod tight against the end of the valve stem. Do likewise for the exhaust valve.

If there are no markings on the flywheel, and it is necessary to time the valves, place one of the cylinders on dead center and determine where these markings should be. To do this it will be necessary to know when the valves should open and close, and this may be found from the instruction book. It may be expressed in degrees, inches of piston movement or in inches measured on the flywheel.

With No. 1 piston on upper dead center, measure off from the top of the rim the number of degrees or inches on the flywheel rim to the mark that indicates the opening of the intake valve of this cylinder. With this mark established, turn the motor until this mark is on top, and then proceed as when this has already been determined by the maker.

If the timing is expressed in inches of piston travel, then the intake valve of cylinder No. 1, for example, should open

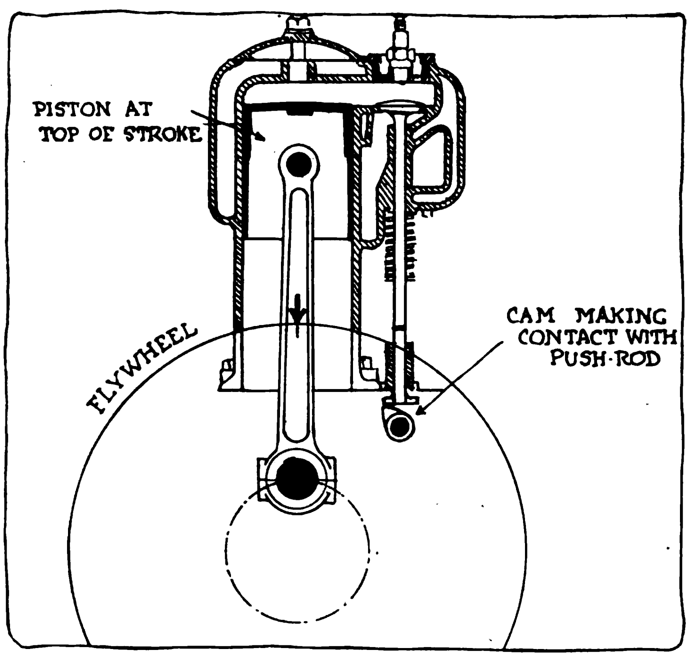

Fig. 6—Diagram showing how valves are timed

when the piston has moved out on its stroke .25 inch. Turn the crankshaft until the piston is this distance below top dead center and then put the camshaft in position.

3—Carbureters are so different in their methods of adjustment that it is impossible to describe the adjustment of more than one model of each of the makes that you mention.

How To Adjust Rayfield

When adjusting a Rayfield carbureter, Fig. 7, bear in mind that all adjustments are turned to the right for a richer mixture; the automatic air valve requires a very light spring tension. Before adjusting the carbureter be sure there are no obstructions in the gasoline line; that manifold connections are absolutely tight and free from air leaks; that valves and ignition are properly timed, and there is a hot spark and good compression in all cylinders.

Set the automatic air valve so it seats lightly but firmly. With throttle closed and dash control down, close the nozzle needle by turning the low-speed adjustment to the left until block Y slightly leaves contact with the cam M. Then turn to the right about one and one-half turns. Open the throttle not more than one-quarter. Prime the carbureter by pulling steadily for a few seconds on the priming lever G. Start the motor and allow it to run until warmed up. With retarded spark, close the throttle until the motor runs slowly without stopping. Turn the low-speed adjustment to the left one notch at a time until the motor idles smoothly. If the motor does not throttle low enough, turn the stop arm screw A, to the left until it runs at the lowest number of revolutions desired.

Then advance the spark about one-quarter and open the throttle rather quickly. Should the motor back-fire it indicates a lean mixture. Correct this by turning the high-speed adjusting screw to the right about one-quarter turn at a time until the throttle can be opened quickly without back-firing. Should the motor not back-fire, turn the high-speed adjusting screw to the left until it does. Then turn to the right until the motor runs smoothly and powerfully.

Adjustments made for high speed will in no way affect the low speed. Should the motor back-fire or the mixture be lean at intermediate speeds, after high and low-speed adjustments have been made, turn the air valve adjustment P to the right, a notch at a time, thereby decreasing the air supply and enriching the mixture. Use all the air possible, for economy.

The low-speed adjustment must not be used to get a correct mixture at intermediate or high speeds. The automatic air valve should always be seated when the motor is throttled down to its lowest speed.

Before starting the motor when cold observe the following instructions: Open the throttle not more than one-quarter (if opened more starting will be difficult); enrich the mixture by pulling up the dash control; prime the carbureter well by pulling on priming lever G for a few seconds. When stopping the motor pull up the dash control. Open the throttle about one-quarter and switch off the ignition. This leaves a rich mixture in the motor, which insures easy starting.

How Schebler Model R Is Adjusted

The model R Schebler, Fig. 8, is a single jet raised-needle type of carbureter, automatic in action. The air valve controls the lift of the needle and automatically proportions the amount of gasoline and air at all speeds.

It is designed with an adjustment for low speed. As the speed of the motor increases, the air valve opens, raising the gasoline needle, thus automatically increasing the amount of fuel. It has but two adjustments—the low-speed needle adjustment, which is made by turning the air-valve cap, and an adjustment on the air-valve spring for changing its tension.

Easy starting is secured by an eccentric which acts on the needle valve. It is intended to be operated either from the steering column or from the dash. It raises the needle from the seat and an extremely rich mixture is furnished for starting and for heating up the motor in cold weather. A choker in the air bend is also provided.

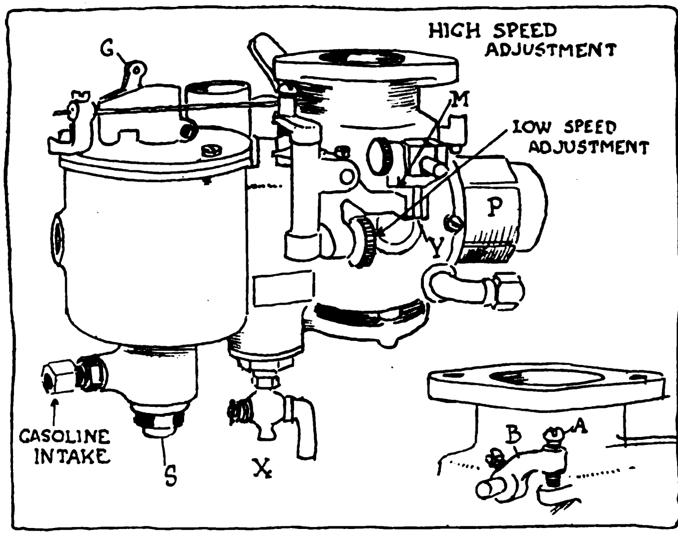

Fig. 7—Rayfield carbureter showing adjustments

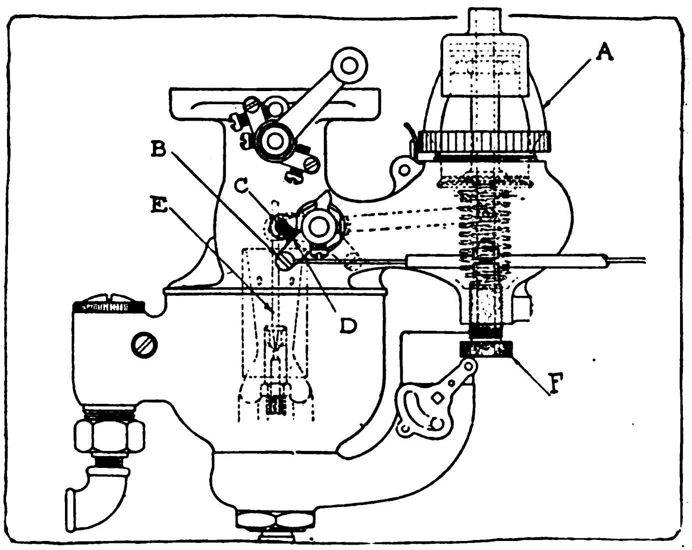

Fig. 8—Schebler carbureter showing points of adjustment

When the carbureter is installed see that lever B is attached to steering column control or dash control, so that when boss D of lever B is against stop C the lever on steering column control or dash control will register lean or air. This is the proper running position for lever B.

To adjust the carbureter turn air valve cap A clockwise or to the right until it stops, then turn it to the left or anti-clockwise one complete turn.

To start the engine open the throttle about one-eighth or one-quarter way. When the motor is started let it run till the engine is warmed, then turn the air-valve cap A to left or anti-clockwise until the engine hits perfectly. Advance the spark three-quarters the way on quadrant; if the engine back-fires on quick acceleration turn the adjusting screw F up (which increases the tension on the air-valve spring) until acceleration is satisfactory.

Turning the air-valve cap A to the right or clockwise lifts the needle E out of the nozzle and enriches the mixture; turning to the left does the reverse.

When the motor is cold or the car has been standing move steering column or dash control lever towards Gas or Rich, which lifts the needle E out of gasoline nozzle and makes a rich mixture for starting. As the motor warms up move the control lever back gradually towards Air or Lean to obtain the best running conditions, until the motor has reached the normal temperature. Then place the lever at Air or Lean.

Why the Industry Flocks Westward

An Analysis by Noted Engineer of the Reasons Which Compel Ambitious Builders of Automobiles, and in Lesser Degree the Makers of Parts and Accessories, to Seek Locations Where Their Efforts Are Upheld and Strengthened by a Multitude of Favorable Industrial and Financial Currents

An Appended Opinion on the Light Cars of the Future

From an Interview with Hiram Percy Maxim by M. C. K.

NOWHERE have more attempts been made at starting automobile manufacture than in New England, and nowhere have the results been less in proportion to the expectations. The accompanying map shows a dot for every factory that has been abandoned. Each of them testifies that the desire to make automobiles has been entertained by individuals. The scale on which New England is engaged in other industries and enterprises bespeaks a disposition which in automobile manufacture should have led to production counting up in numbers as high as anywhere else in the country if the conditions had been favorable. New England always had plenty of capital, hosts of capable machinists and other mechanics, all the financial grit needed for tackling new problems and all the persistence required for solving them.

Why, then, does not New England today produce more than 1 per cent. of the automobiles made in the United States? And why does any proposition to locate a new factory in New England, or to revive an old one, meet with a chilly reception among the financiers of that section? Why, on the other hand, does the manufacture of automobile accessories and of special machinery with which to make automobiles on the Western scale prosper much better in New England than the manufacture of the automobiles themselves?

These questions which have a bearing not only on the past but also on the future, whenever the matter of locating a manufacturing plant is involved, seem sufficiently interesting to justify an attempt to get them answered as authoritatively as possible, so much more as the answer might throw light on similar questions in other sections of the country. The cyclecar movement, among other radical factors in the present situation, might, for example, easily call for the establishment of new factories, and New England, New York State or Pennsylvania might seem to afford excellent opportunities for opening up new manufacturing business, as the chances for a thriving local trade, to help the beginning, apparently would be brighter there than in the Middle Western territory where factories abound. Also, the fact that export trade on Europe, South America and Asia looks promising, and would be a welcome filler to even up the fluctuations in the home demand, beckons the new concern to an eastern location.

A man who seemed particularly well qualified to shed light on any questions asked in this connection was found in the person of Hiram Percy Maxim, whose work as designer and builder of automobiles dates back to the very beginnings of the industry and who has been located in the midst of all the New England industrial currents and cross-currents almost without interruption ever since, while still maintaining close touch with friends, associates and subordinates who drifted West and followed the rising tide of automobile manufacture in Cleveland, Detroit and other bustling centers for the new activity.

A visit at the Maxim Silencer works at Hartford did not fail to elicit the expected ideas, clear and definite, on the subject.

Prosperity the Main Obstacle

"New England is too prosperous in other lines. If New England were finding it harder and harder every year to make money, the situation might be different. But this is not the case, not yet. For every plan to make a big success of automobile manufacture, the New England business man counters with a plan for making a bigger success in finance or insurance or in some of the old established industries, on a much smaller investment and on lines with which he is familiar. New England is making more money on these lines than ever before."

"Still the many who have started must have had an idea of continuing," it was suggested.

"But when it came to the point, in each case, of doing what should be done, to improve, to enlarge to meet competition, the helping hand which is extended so freely in the West was not found; it was engaged in other directions."

"You don't think that the mechanics of this section are too capable along fixed lines, too conservative and averse to new modes of working? Or that there is a scarcity of hands to tend automatic machine tools."

"The mechanics are all right. The trouble is with the investors.

"The mechanics as a rule are full-skilled and full-paid, to be sure, and there has not in this line of work been much employment for the class of factory hands whose only skill consists in tending special machinery, but this is because the manufacture of automobiles here in most instances has not advanced to the point of organization at which highly specialized machines could be bought.

Successes No Longer to Be Duplicated

"New England makes special automobile machinery but it is sold elsewhere. The orders come from other parts of the country. And things have changed. A concern like that of Pratt & Whitney, which I started, could not be started now, successfully. Billings and Spencer have doubled their business three times over, since automobiles began to be made, but no other similar concern could do the same now from a New England location."

Different Situation of Partsmakers

"To what do you ascribe the fact that New England continues to succeed in making automobile parts on a large scale?"

"A concern starting in to make a certain part selects one which it can make with the equipment it has. There is no new investment. The concern is bigger than the new business it undertakes from the beginning. Later, if the partsmaking end of it grows to be the main thing, enlargements and improvements can be made out of the profits, and they know then what they are doing. New England business men are not slow; not so slow that they won't buy new machinery if they can see the need of it plainly and no better use for their money, but they are certainly loath to throw old machinery on the scrapheap. The partsmakers usually can find a place for the old machines which have served them in the past, even if they have to install new machines as well."

The Force of Example

"Is there going to be any change in this whole condition?"

"How can there be?" it came quickly from Mr. Maxim, "it is logical. It is easier to go West and find suitable conditions. People follow the lines of smallest resistance. Nobody can afford to spend more than half of his energy in overcoming the drag. The force of example is against you instead of for you; and it is powerful. Let me mention an instance. In 1902, when air-hardened tool steel was still a relatively new thing, I was out at the Pennsylvania Railway shops at Altoona where they had just installed a high-speed lathe. It cut big clean red-hot shavings, bigger than any of the workmen had seen before and faster, much faster, the cutting edge of the tool red-hot too, and the men gathered around the machine to watch it, whenever they could. Its new efficiency impressed them deeply, and they went back to their benches or their machines and worked with much greater energy than before. They simply could not work at the old slow gait with that lathe setting another example before them every day. There was a clear gain of 100 per cent. in the speed of all the workers in that shop, and they tell me that this advancement was maintained ever afterwards. So much for one single example, and an inanimate one at that."

The Money Not All

"Could a Western man or set of men with liberal ideas and sufficient capital come here and organize automobile manufacture on a large scale, starting with small and cheap cyclecars, for example, and developing a simplified type of automobile in which New England might come to excel?"

"Perhaps, but I don't think they could. At least they could do better by placing their plant in the midst of helpful surroundings, with the rest of their community, as well as neighboring communities, interested in the success of automobile manufacture and anxious to help pushing. The ambitions of New England, on the other hand, run in the directions where the biggest money is made now by New Englanders. Changes in this come hard."

"To show the difference in the spirits of things," Mr. Maxim continued, "I will mention another example. The agent for a spotwelder recently came to a St. Louis concern where a great deal of riveting was being done on stoves and convinced them that they could save $25 per day and get the work done better with a spotwelding machine. With riveting, you know, there is a lot of waste work in indexing the holes. 'Will I have it sent by express?' the agent asked. By express! a machine weighing 700 or 800 pounds. The charges would be $100, how ridiculous! 'Why not?' responded the agent, 'you save 10 days in time over fast freight. At $25 per day that is a loss of $250. Deduct $100 for express charges and you are still $150 ahead.' In five minutes the St. Louis concern had placed the order, to be shipped by express. The same agent shortly afterwards made a thorough demonstration with a similar concern in ———, here in New England. The order was placed, but when it came to the question of shipment, though the conditions were parallel, the New England firm rebelled vigorously. To pay $100 to an express company for a bit of transportation which could be done for one tenth of that sum was against all sense and precedent, whether it looked like a saving or not. It could not be done. And it was not done. This difference between the West and New England crops out at every turn. It seems to be in the blood here; yet, when a New Englander goes West he gets into the new spirit in a week."

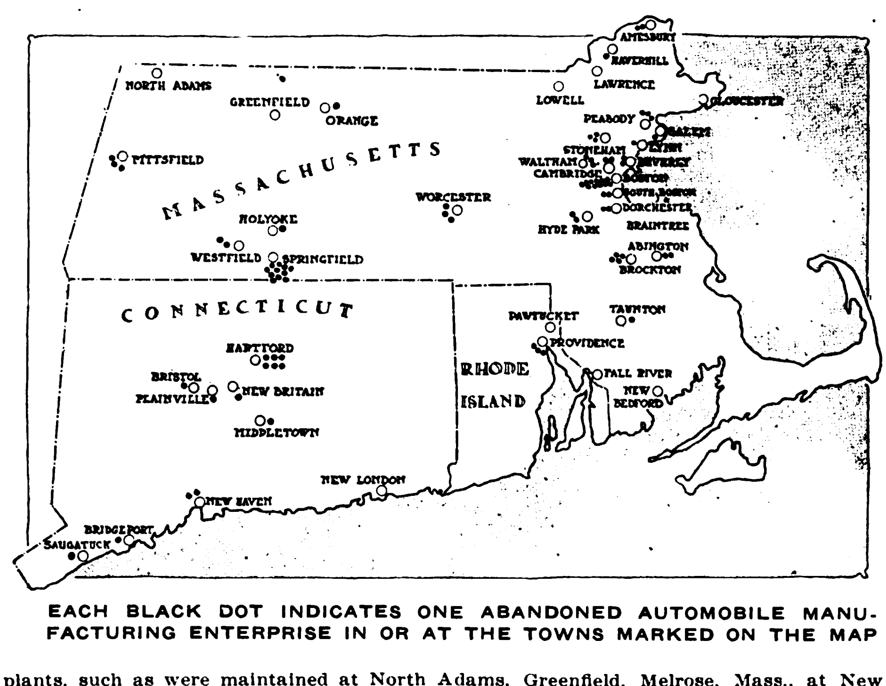
Other examples were mentioned, so actual that they cannot be detailed, but tending to show how very loath the prosperous New England concern is to scrap any part of the machinery which is still in working order and with which he is able to make profits so long as no modernized competition has gained headway. Government contracts and much other profitable work still find their way to New England firms which have the prestige of an industrial position of long standing but whose equipment is antiquated.

"It seems that the New England industries need Taylorizing," suggested the interviewer, "if they shall keep permanently ahead, in other lines than automobile manufacture."

"There is an entering wedge in the Taylor system and the manner it is being advanced," Mr. Maxim thought, "which seems rather congenial to the New England spirit. It is taken up in several places here. Still, that is a long road."

—

During this discourse, all the while he was gaining a



EACH BLACK DOT INDICATES ONE ABANDONED AUTOMOBILE MANUFACTURING ENTERPRISE IN OR AT THE TOWNS MARKED ON THE MAP

Early experimental plants, such as were maintained at North Adams, Greenfield, Melrose, Mass., at New Haven, Danbury, Conn., and at many other places before the year of 1902 are not included in the map. The names identified with the abandoned factories recall many a worthy industrial struggle, as follows: In **MASSACHUSETTS:** **Boston**—American Automobile and Power, Lyman & Burnham, Radford, Richmobile, Sturdevant-Mill, Razoux, Napier, Ariel, Essex, Bay State, Holmes. **Springfield**—Warwick, Knox, Automotor, Springfield Automobile, Morse, Rogers, Knox Truck, Atlas, Bailey, Med-Bow, Sultan. **Abington**—Lamson, Buffum. **Brockton**—Motor Cycle, American Motor, Cameron, Roader. **Waltham**—Waltham, Metz, Metz Company. **Cambridge**—Crest, Berkshire Motors. **Westfield**—Loomis, Westfield Motor Truck. **Hyde Park**—Robinson, Pope-Robinson. **Orange**—Grout. **Worcester**—Morgan, Morgan Company, Morgan Motor Truck. **Pittsfield**—Berkshire, Alden Sampson, Stilson. **Amesbury**—Boston and Amesbury, Crown. **Stoneham**—Phelps, Gray & Couch, Shawmut. **Beverly**—Upton, Cameron. **Dorchester**—Clark, Crest. **Salem**—Locke Regulator. **Holyoke**—Matheson. **Taunton**—Taunton Motor Carriage. **South Boston**—Gilmore Electric. **Lynn**—General Electric (automobile department). **Peabody**—Vaughn, Corwin, American Coulthard. **Haverhill**—Hill. In **CONNECTICUT:** **Hartford**—American Cycle, Electric Vehicle, Law, Maxim & Goodridge, Columbia, Kelsey. **New Britain**—Corbin (automobile department). **Middletown**—Eisenhuth. **Plainville**—Bristol. **Saugatuck**—Toquet. **Bridgeport**—Ariel. **Bristol**—Bristol Engineering Company. In **RHODE ISLAND:** **Pawtucket**—United Motor Corporation, Brown Machine. **Providence**—Builders' Iron Foundry, "Alco," Page. At **Rumford,** Maine—Bonton.

new and clear view to explain why the automobile industry has flocked, and continues to flock to the West, the interviewer could not help being impressed with the sturdy ability which must have been displayed in the automobile manufacturing concerns in New England—with which the States of New York and Pennsylvania perhaps should be included—that after all have managed to fight winning industrial battles without falling in with the helpful tide of the westward current, compelling respect and patronage on the strength of individuality of design and construction.

Another matter suggested itself. The occasion for getting the opinions on the future from one whose judgment has been matured under these severe conditions could not be neglected. In consequence, Mr. Maxim was plied with more questions relating mostly to those things which are radical and prospective in automobile design. The answers, bound to be rendered in a limited space, had to be given word for word, so as to convey nothing more and nothing less than that for which Mr. Maxim would assume the responsibility. And for this reason they were given in the form of a letter—which makes it plain, too, what questions were asked—as follows:

The Coming of the $250 Light Car, Fully Equipped, a Certainty in the Light of Previous Development of Automobile Engineering

My Dear Mr. K.:

The following is what I have to say regarding the questions you asked me here in Hartford:

I think we are decidedly in a position to be able to revise our automobile engineering knowledge so as to produce a commercially successful **light motor car.** In looking forward from a standpoint of established fact to what seems to be a logical possibility, we must take past history as our chief guide. Let us briefly analyze automobile engineering history as it relates to this particular question:

We began by concerning ourselves exclusively with what was necessary in order to "keep the machine going," regardless of any other consideration. Breakdown, was the great nightmare before us. Cost to manufacture and market were subordinate questions.

Then came the middle period, when the most skillful of us saw clearly beyond dispute that we had the knowledge of how to produce a machine which would "keep going indefinitely." This conviction developed a new school of automobile engineering. It was evident that with this knowledge of how to produce a motor vehicle which could be absolutely depended upon inspired certain of us to see how **cheaply** we could produce this reliable motor car. The low price astonishingly successful vehicle appeared forthwith. This is where we stand today.

Now, there are certain of us who realize **two big facts** —that we have the knowledge necessary to build a thoroughly reliable machine, and that we also have the knowledge necessary to build this machine and sell it for $500. This has inspired certain of us to take the third step: To alter our original engineering practice enough to accommodate the new manufacturing possibilities, **and to produce a motor vehicle for $250.** There are a lot of us who are convinced that this can be done, just as there were some of us in 1903 who were convinced that a successful car could be made and sold for $500.

This idea is fixed in men's minds, and we know that once an idea is positively fixed there will be a man come along who will carry out the idea successfully. The light cheap car will come, and nothing can hold it back, in my judgment.

As regards **starters, gear shifters and transmissions,** I believe these will undergo astonishing simplification **after** the light car has come into its own. It is just as logical to believe that a cheap and thoroughly good starter will be produced when the demand for it has been established, as it is to believe that a cheap and thoroughly good motor car will be produced. Tremendous possibilities exist when the demand is big enough. I expect the starter will be operated by gas, as this is both light and cheap, and I expect the lighting will be electrical with something very cheap in the way of a primary battery for carrying the load when the engine is not running. But, this is only my own personal analysis, and really should not be given, since we are engaged in this discussion in considering broad questions only.

In the case of gear shifters and transmission devices, I fully believe that we have every right to assume that we shall duplicate in the cheap light car every improvement developed for the high priced car. If semi-automatic gear shifting becomes general, a way will be found to semi-automatically shift the gears on a light car by an extremely cheap-to-build and light-weight device.

Just so with transmissions. If an hydraulic or an electric transmission comes on large cars, a duplicate will be found for the light cheap car. The law applies on accessories in exactly the same manner that it applies to the complete motor vehicle.

In the matter of Dr. Steinmetz's expressed belief that the electric motor car will be the car of the future, I am unable to believe that Dr. Steinmetz intended this to apply immediately, or within the next ten years. We all expect that eventually we will find a way to develop power from some previously prepared and intensely concentrated fuel, and that this fuel will be applied electrically. But, we do not consider we have the right to expect this until several new **discoveries** have been made, and not merely new inventions. We are as far as we can go electrically, in motor vehicle matters, until some new discovery is made, in my judgment.

As for your question regarding whether the average citizen [motorist] will ever catch up to the technical understanding of the internal combustion motor, and its accessory apparatus, I do not believe it is necessary. He will never catch up to any specialty, whether it concerns an internal combustion engine or a surgical operation. The average citizen is a composite of many composites, and all he asks is that you give him something which will **get him there and back** with the expenditure of ordinary average intelligence. If you don't someone else will, and he knows it, and he will buy from the other fellow.

Very truly,

June 27, 1914. *Hiram Percy Maxim.*

The question of location is one so momentous to every new concern and to every firm contemplating a change that no one man's opinion on the subject can be considered as exhausting its interest. The fact that Chicago, for example, has never become a large center for automobile manufacture may not be fully explained by the superabundance of other financial interests in that city and its vicinity; yet they may have influenced the results. Everywhere the personal elements and those depending upon the currents of information and assistance, financial, mechanical and industrial, in which a manufacturing concern finds itself placed, are so intricately mingled that final conclusions are difficult to reach except in the case of strongly marked movements involving large districts. That bonuses and municipal concessions may play an important part in influencing a decision on location is usually conceded, but in the history of the industry these considerations have rarely proved themselves decisive for full-grown success in the long run.

Broad and reasoned viewpoints on the whole matter, illuminated by examples, could not fail, if they were forthcoming, to help in bringing clearness in a matter which is often decided somewhat at random, on purely personal or local grounds, and in many other cases is allowed to drift along for years unsatisfactorily. The views of Mr. Maxim seem very helpful to start thought along definite lines, while those relating to design and cost no doubt will rouse contradiction.

The Engineering Digest

Concurrent Control of Fuel and Air in Bréguet's Carbureter

LATELY a large number of Gnôme and Rhone motors in French aeroplanes have been fitted with Ramondou carbureters, which are a recent invention by Bréguet, the well-known aeroplane designer and builder. Practical tests had shown that they were more economical with fuel—in the case of motors with revolving cylinders—than the best carbureters before used and also that they produced a higher maximum power—both items of the greatest importance for aviators.

The characteristic of the Ramondou carbureter is that the gasoline and the air supply are regulated simultaneously to produce the same proportions in the gas mixture at all motor speeds.

The carbureter body A has at the narrowest place of the suction channel a lateral cylindrical appendage in which two concentric and hollow pistons I and J can be moved to regulate the cross-sectional area of the suction channel from zero to maximum, as in other cases done by the throttle. Piston I projects at one end, where it is provided with an eye for attachment to a control rod, from the cylindrical body and contains in its bore the valve needle B which at its opposite end projects into the jet and fuel feed tube F. Spring K establishes an elastic connection between pistons I and J. In the position shown in Fig. 1, in which both pistons completely close the suction channel, the needle B also shuts off the fuel by pressing the conical portion Z against the mouth of tube F.

The regulation of the two pistons in the opposite direction is limited in two ways. The piston I can be pulled into the cylinder until the flange S abuts against the end of the adjustable threaded sleeve T, while piston J can follow this movement only till it is stopped by the ends of screws M which sit in the ring D, provided with the lever H, and themselves can be adjusted. The manner of adjusting the threaded sleeve T by means of the screwhead E and the locknut V is plain from the drawing. The ring D is moved slightly up or down, when lever H, to which the air-control rod is attached, is turned, as the screws M follow oblique slots in the cylinder wall. The spring K comes into action when piston J is stopped by screws M while piston I and needle B are pulled farther out. Spring L serves only the purpose of steadying the needle valve.

Rapidly Regulated

The regulating of the carbureter is done as follows: After the motor has been started, the suction channel is first throttled to a small opening—2 to 3 millimeters—and then the fuel feed for still-running is adjusted once for all time by screwing the jet tube F in or out, after loosening the locknut U, so as to regulate the interval between the mouth of the tube and the needle at the conical portion Z. This adjustment once found and the locknut re-secured, the regulation for full power is made. To this end the piston I and the needle are pulled out till the maximum power is obtained, locknut V is loosened and sleeve T is screwed into abutment with flange S. The proper amount and velocity of air at this adjustment is obtained by means of lever H which, as mentioned, limits the opening of piston J.

After these permanent adjustments the carbureter will thus produce the correct fuel proportions as well at still-running and very slow speed as at the highest velocities, and it is the designer's theory, which has been found supported by the practical tests, that the proportions must also be right at all intermediate speeds by reason of the simultaneous opening or closing of the jet and the suction channel by which the throttling operation for any desired power effect is made.

Furthermore, the lever H, though normally left untouched, may be separately operated if a change in atmospheric conditions—altitude, humidity—should make this desirable.

Security against carbureter fire is to some extent obtained through the fact that the fuel is shut off when the suction channel is closed, and any striking out of a flame is prevented by the double metal-gauze screens O in the air-intake drum and the S-shaped course a flame must follow to reach them, causing it to spend what force it may have against the slightly springy aluminum bell G.

In applying this carbureter to an aviation motor with revolving cylinders, it is connected by a right-and-left thread union nut directly with the end of the hollow crankshaft, as is the general practice for Gnôme motors. It can also be applied with an intermediate elbow, so as to bring the plane of the air-intake parallel to the direction of movement. The principle of this carbureter should be applicable to automobiles.—From *Der Motorwagen*, June 10.

Saving a Little Weight and Wear in Sliding-Gears; Vibration Too

IN all gear boxes the wheels, when in mesh, are directly opposite each other, as in the left portion of Fig. 2, and the chamfered portions of the teeth, while necessary for easy shifting of the gears and to avoid burring them, represent a certain waste in the useful width of the metal, as they constitute narrow zones on both sides of the wheels, and these zones are out of engagement and yet so close to being engaged as to give rise to noise and vibration. It is now proposed

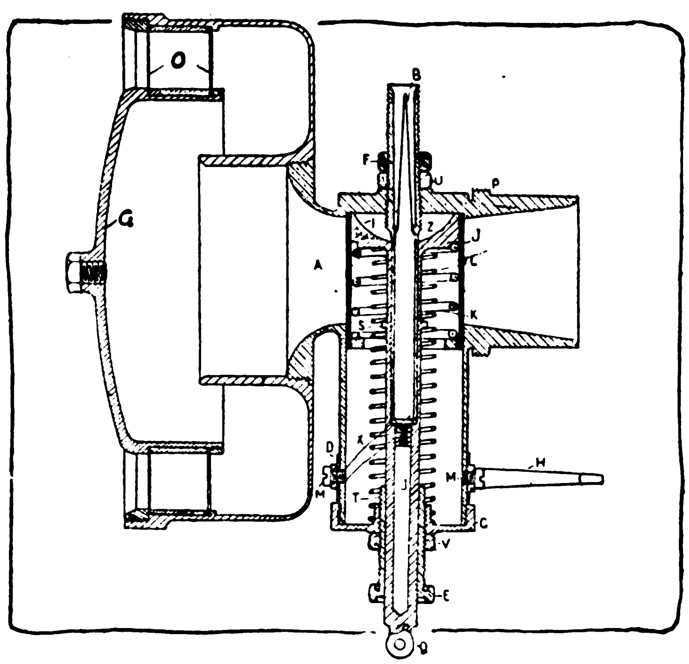


Fig. 1—Ramondou carbureter, aeroplane style

to remedy this and gaining the width of one of the zones for the metal in engagement by arranging to push the slidable gear so far through that the chamfered zones of both gear wheels are released, as shown to the right in Fig. 2, while the entire width of the straight portions is engaged.

In practice the tapered portions of the teeth correspond to a width of about 3 millimeters in the ordinary four-speed gearbox with three sliding members. In this case, if the improvement is applied to the three reduced gears, the application to the third speed does not lengthen the gearbox at all, while the application to the second speed lengthens the box by 3 millimeters; and, further, if the wheels for the second and third speeds on the intermediate shaft are in one piece, the slidable wheel enters the space left for the disengagement of the sliding-fork.—From *La Technique Automobile*, June 15.

Sightly Device for Securing Nuts and Bolts—Tests Favorable

SPRING washers and split pins are the most favored means for securing the nuts on the ends of bolts in automobile construction in cases where they afford sufficient security, while locknuts of the depth required for real efficiency are deprecated for looking clumsy and adding to the necessary length of the bolts. New devices intended to supply the long-felt want of a thoroughly acceptable contrivance are therefore constantly forthcoming, while automobile and accessory designers, on the other hand, strive to reduce the number of bolts used in a construction to a minimum, even resorting to riveting in many instances, on the plan that the riveted end of a bolt can be chiseled off, in case of necessity for taking the construction part, and the bolt replaced. Retaining-flanges and autogenous welding are also employed more and more where formerly bolts and nuts abounded.

The latest locking device, heralded from France, is shown in Fig. 3 and has been tested at the laboratory of the Conservatory of Arts and Trades. It was here shown that a locknut turned on with a pressure of 5 kilograms at the end of a wrench .40 meter long came completely loose after 80 shocks, while the *autobloc*, as the new device is called, though secured by hand only, remained in its place after 103,000 blows. It was also found that the work required for turning an *autobloc* nut without its locking piece amounted to 3.2 gram-meters, while with this piece in place the work required rose to 2,720 gram-meters. Prolonged use of the device on the locomotives of the Metropolitan in Paris has confirmed these results.

A peculiarly shaped slot in the nut and the locking-pin constitute the whole provision, the bolt remaining whole and no longer than needed for taking the nut. The slot has a rocking-edge on its outer side and a curve on its inner side. The pin has rectangular faces and is thinner at one end than at the other; the face turned toward the bolt is grooved lengthwise to correspond with the thread of the bolt. It seems that the grooves are straight. When the pin is driven into its place, it is squeezed between the sharp ridge on the outer wall of the slot in the nut and the much larger contact surface with the threads of the bolt. When a tendency to loosening of the nut manifests itself, the pin therefore turns with the bolt and is wedged the harder in the slot the stronger the tendency to loosening becomes.—From *Omnia*, June 27.

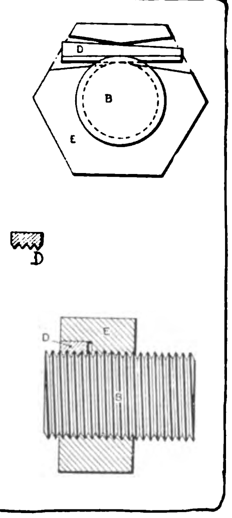

Fig. 3—Nut lock

Double Eccentric Worm Adjustment —An Important Improvement

IT is known that the correct mounting of a worm drive is so complicated and difficult that this feature more than any other has retarded the adoption of this driving system, says Mr. Decoux and quotes in confirmation of this assertion Mr. Perrot, chief engineer of the Argyll works where a good thousand of worm-drive vehicles have been turned out. Mr. Perrot's remark is: "The worm must be mounted absolutely in the middle plane of the worm wheel; the smallest deviation causes considerable friction, and the drive heats up." The simplest method for overcoming all difficulties involved in this peculiarity consists in employing a double eccentric adjustment on the principle indicated in Fig. 4, according to Mr. Decoux. It is patented, he says.

The worm shaft A is mounted with its bearings in two eccentric sleeves B and C. One of them can be the torque tube and the other can be operated from the rear. By turning one of the eccentrics the worm shaft is displaced to the right or left, to center it in relation to the wormwheel. If it is desired to adjust the shaft vertically, it is sufficient to turn both eccentrics an equal amount in opposite directions. The regulation is thus obtained without need of adjusting the wormwheel, so that its alignment with the other organs of the construction, such as the gearbox, is conserved.

By this method the axis of the worm shaft can be taken to any position within a circle which has for its radius the sum of the two eccentricities. The plan facilitates machining and mounting and readily admits of changes in the transmission-ratio. It can also be applied to the steering gear and for the centering of brake shoes. In the case of the worm drive, a system for locking the adjustments has also been devised.—From *La Technique Automobile*, June 15.

The Oiling of High-Speed Motors

AT the recent Tourist Trophy run on the Isle of Man the majority of the involuntary stops were caused by deficient cylinder oiling, doubtless due to exaggerated linear piston speeds, according to a French observer's report. Fractures of mechanical components were practically unknown and the tires gave little trouble. With regard to the oiling it is noted, however, that all the motors used in the race, excepting that in the Straker Squire car, were specially designed creations, this including the Knight motors in Minerva cars, which were provided with an auxiliary exhaust.

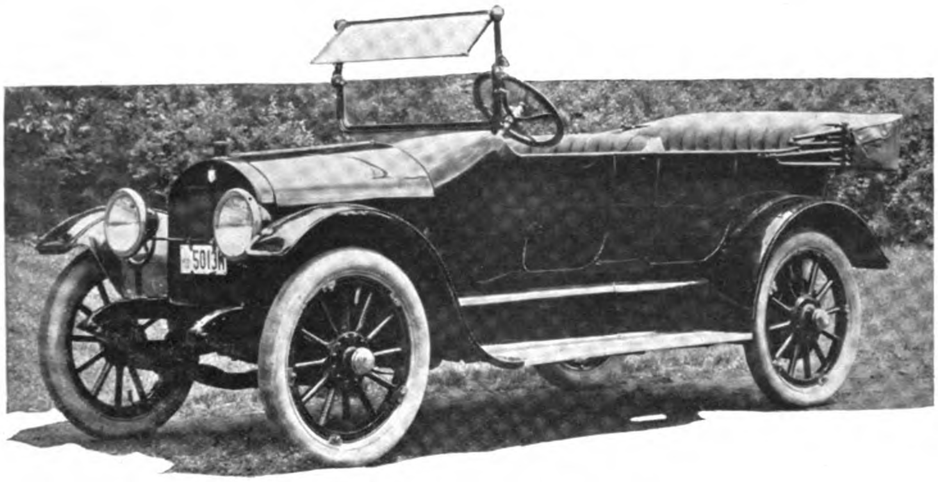
Stream Lines Distinguish 1915 King



King for 1915 with larger motor, streamline body and crowned fenders for $1,165

Plan view of 1915 King showing seating arrangement

Bore of Cylinders Increased 1-16 Inch —Wheel-Base Lengthened One Inch— Brakes Improved — Inside Upholstery

RADICAL changes mark the introduction of the King car for 1915. A larger motor, streamline body, crowned fenders and a reduced price are the three most prominent innovations. With the new body and the many refinements the new King bears but little resemblance to its namesake of a year ago.

1/16 Inch Added to Bore

The most important change mechanically is the addition of 1-16 inch to the bore of the cylinders, making them 3 15-16, the stroke remaining at 5 inches. This adds materially to the power output, although the manufacturer's rating has been left at from 30 to 35 horsepower. The S. A. E. rating is 24.8 horsepower.

The latest idea from Europe is that the upholstery is placed entirely inside the body, none protruding over the edges. This is a harmonious touch which is distinctive.

Cantilever Spring Mounting New

Although retaining the cantilever rear springs which have always been a characteristic feature, a modification has been made in the manner of attaching their rear ends to the axle housing. The former plate-and-sleeve construction on the axle housing has given way to a hinge form of attachment. An eye bolt through the lower leaf of the spring secures the latter to a sleeve around the housing.

In connection with this spring mounting change, the forward end of the torque tube is attached to the lower side of the gear box by a slip joint which allows free end play to the torque tube while preventing injury to the end thrust bearing in the universal joint due to side thrusts occasioned by changes of positions of the outer ends of the rear axle in conforming to the irregularities of the road.

New Axle Housing 50 Pounds Lighter

The wheelbase has been lengthened 1 inch to 113 inches. A pressed steel axle housing now is provided to replace the east type formerly employed. This new housing is 50 pounds lighter. The axle itself is of new form in that a floating construction supersedes a three-quarter floating one. Option of either a 3.7 to 1 or a 4 to 1 ratio is given. The latter for hilly country.

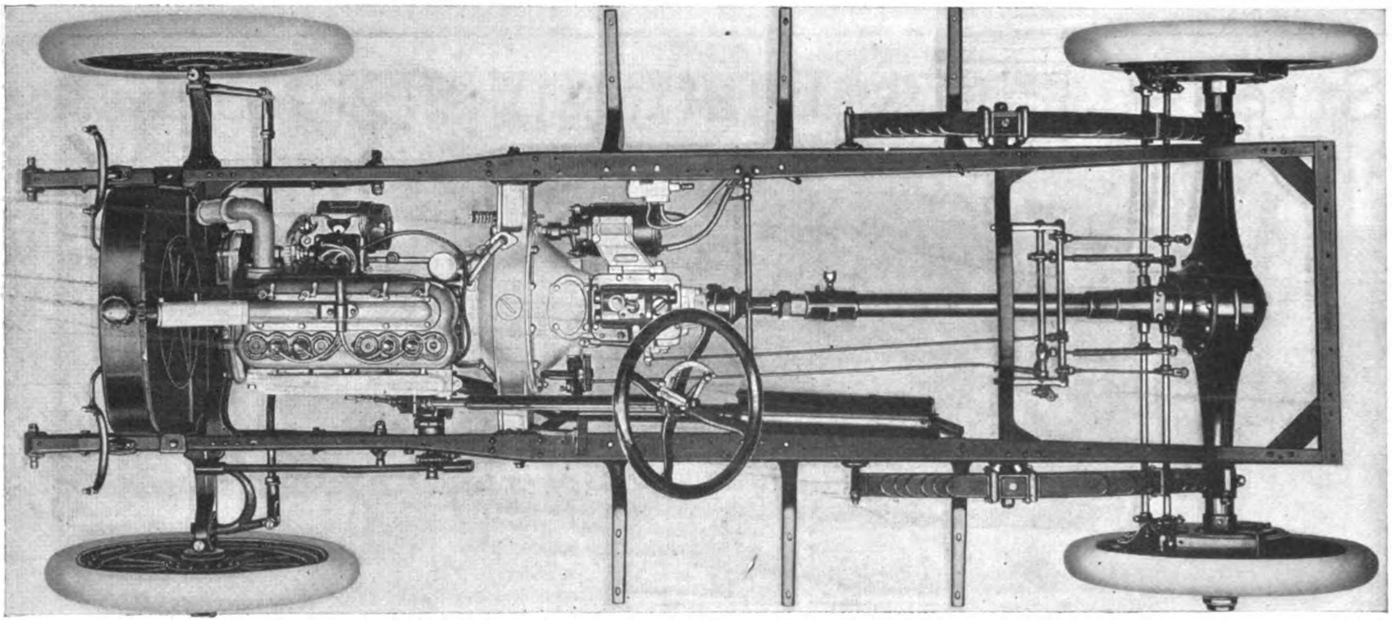
The brakes, too, have come in for some change to make them simpler and more efficient. The internal bands are of the full wrapping type for operating practically the entire circumference of the drum, as compared with the semi-wrapping or crescent-shaped band used in the preceding model. Operation of these internal bands is now by an S cam instead of by toggle joints.

The general construction of the engine has not been changed because of the bore increase. It is an L-head type with both manifolds on the left and is three-point suspended from the main frame, the clutch and gearset being in unit with the crankcase. The aluminum crankcase is horizontally split into halves.

Both intake and exhaust manifolds are separate from the cylinder block, and bolt to it. There is an individual opening into the exhaust header from each exhaust port, while in the case of the intake one opening into the block takes care of the distribution internally to two intake ports. One manifolding change is the shortening of the intake and causing the carbureter to be mounted higher. This is made possible by the location of the fuel tank in the cowl and makes the Stromberg carbureter more accessible, besides tending to greater mixing efficiency since there is less pipe length for condensation.

Spiral timing gears are used. There is only one exposed shaft, that being on the right and driving through belt connection the fan, the ignition distributer and the generator, when the latter is supplied.

A honeycomb radiator replaces the formerly used vertical tube pipe. It is more efficient and its appearance attractive, the front edges being coped after present-day fashions. The system is thermo-syphon. The inlet connection to the block is at the front right side, the distribution to the jackets being an integral part of the casting.



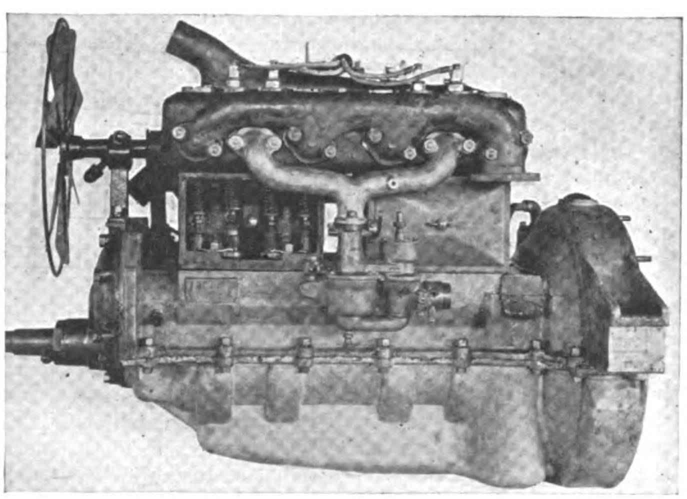
Plan view of King chassis, showing new slip joint attachment at forward end of driveshaft housing

The lubrication system is a combination of force feed and splash, the flywheel acting as a pump and delivering the oil to the crankshaft bearings and the timing gears. Rotating in the oil, it throws oil into a scoop or trough by centrifugal force. Thence it goes to the bearings. The cylinder walls and pistons receive the splash from the connecting-rod ends dipping into the splash troughs, there being individual troughs.

Flywheel Acts as an Oil Pump

The ignition has been entirely changed, the magneto being replaced by the Atwater-Kent system. The distributer is mounted where the magneto was formerly placed, being driven off the end of the fan and generator shaft. The chief advantage claimed for this change is that there is a gain in flexibility at low speeds due to the fact that the current supplied by the battery is constant regardless of the speed of the motor.

The Ward-Leonard cranking motor and generator are separate units, with the generator mounted below the ignition unit on the right of the engine, and driven by silent chain from the shaft. This chain is not enclosed and allows the ready removal of the generator. Generation of current reaches its maximum at from 10 to 15 miles an hour car speed, the generator being driven at twice engine speed. A special controller keeps the Willard 80-ampere-hour battery charged fully and prevents too rapid charging, at the same time allowing full rate at the car speed mentioned.



Left side of King motor showing a high mounting of carbureter

The cranking motor unit is located at the right side of the gearbox, to which it is bracketed and is a more powerful one than its predecessor, being capable of turning the engine at from 135 to 140 r.p.m., as compared with 90 r.p.m. The reduction gearing between it and the flywheel has also been simplified, one of the intermediate gears having been eliminated.

Starter Control Has Been Improved

The starter control has been improved and in place of the old pull-up handle there is now a lever between the front seats at the driver's right which is operated by pushing forward. The starting system is a two-wire type of 6 volts. There are large and small bulbs in the head lamp for city and country driving.

There are nine bronze disks and an equal number of saw steel disks used in the clutch whereas in the preceding model all disks were of steel. The disks are provided with cork inserts instead of being faced with an anti-friction material, as heretofore. The new clutch is very easy in action. The three-speed gear set uses chrome nickel gears, as compared with the combination of carbon and nickel in the older models. Ball bearings have given way to Hyatt throughout the gearset. A ball-and-socket lever controls the shifting instead of the cross type used before.

In line with the other body trimness, the fenders are crowned and conform closely to the contour of the wheels. The instrument board containing gasoline gauge, electric light switches, ignition switch, speedometer and speedometer light is another new feature which brings the new King up to 1915.

Gasoline Tank in the Cowl

The gasoline tank is located in the cowl and contains 12 gallons, the filler being at the right side so as not to interfere with either occupant of the front seat. A gasoline gauge is also provided. The previous model had the gasoline tank under the front seat.

A notable manner of clearing the running boards of any obstructions is found in this new model. The storage battery is placed under the front seat at the driver's right, the tool box being located under the drive seat. These are therefore both very accessible, while the space under the rear seat is left for luggage. The extra demountable rim and tire are carried at the rear. Tires are 33 by 4 front and rear.

Steering is on the left, the gear being of Gemmer make and operating through an 18-inch wheel. Cast aluminum spark and throttle levers on the wheel are a new thing in motor car construction, they being usually made of steel and nickeled. These aluminum controls naturally cannot tarnish and are amply strong. The horn button is conveniently located in the center of the steering column above the wheel.

The equipment takes in everything now demanded by the driver. There is a rain division windshield, silk mohair one-man top, quick detachable side curtains, Stewart speedometer, electric horn, demountable rims with one extra and a complete outfit of tire tools, machine tools and jack.

The 1915 series, known as model C, comes in roadster and touring car, and the application of the Ward-Leonard cranking and lighting system is optional as it was last year. With this equipment the new price with either body is $1,165 as compared with $1,195 last year when similarly equipped. The price without these electric features is now $1,075, or $20 less than previously.

Metz for 1915 Has New Fore-door Body

IN producing its 1915 model, the Metz Co., Waltham, Mass., has paid a great deal of attention to the details of body design, with a view to perfecting the car's appearance but no mechanical changes have been made, as none were found necessary. The price remains at $495.

The new car is characterized by a streamline body, with tapering hood, sloping cowl, high doors, and a slanting rear deck. The new windshield is a two-piece, design that is fully adjustable. Another departure is the removal of the lamps from the fenders they now being attached at either side of the hood. They are reinforced by a connecting bar. A Prest-O-Lite tank has been substituted for an acetylene generator. The body changes have necessitated increasing the wheelbase from 90 to 96 inches and this also improves the looks of the machine. The gasoline tank, holding 10 gallons of fuel, is concealed in the cowl and feeds by gravity.

Mechanically the 1915 Metz, is exactly the same as the 1914 model, the leading characteristic of which is the friction speed changing mechanism from which drive is taken through a jackshaft and side chains to the rear wheels.

The four-cylinder motor has block-cast, L-head cylinders 3.75 by 4 inches, the S. A. E. rating being 22.5 horsepower. The valve stems and springs are inclosed and both crankshaft and camshaft, which are steel forgings, are finished by grinding and run in white metal bearings. Lubrication is by a constant level splash system with pump circulation of the oil; and cooling is by thermo-syphon, the capacity of the system being 3.5 gallons. The carbureter, which is made by the Metz company provides the proper mixture at all speeds and ignition is effected by a Bosch high-tension magneto.

Friction Drive Employed

The friction drive is effected through a disk and wheel, the wheel being shifted along the face of the disk to gain the different speeds. From the wheel the power is transmitted to the drive shaft by a single silent chain; and from the jackshaft which carries an inclosed differential, the drive is transmitted to the rear wheels by side chains which are inclosed in tight cases and operate in oil. The gear ratio is 3 to 1 on high.

The frame is of pressed steel and is supported by full elliptic springs all around. The wheels are wood, 30 inches in diameter and are shod with 3-inch tires. The braking equipment of the machine is unusually complete there being a set of internal expanding brakes on the rear wheels, an external contracting brake on the jackshaft, and besides, the friction disks may be used for braking purposes. All wheels run on ball bearings and the tread is 56 inches.

Dodge Car Newest in Light Field

Dodge Motor Car Co. Offers Electric Starting on $595 Car Weighing 1,400 Pounds

THE Dodge light car has just been brought out by the Dodge Motor Car Co. of Detroit, which must be distinguished from Dodge Bros. of the same city. The Dodge car which is referred to here is made by the company which has been named after its president, Alvan M. Dodge who was formerly associated with the Wahl Motor Car Co.

The new car is a two-passenger type of standard tread having a sloping hood and rounded top, giving a more or less foreign appearance. The complete weight of the car with tanks filled is 1,400 pounds.

In offering this new light car, the Dodge company makes two optional prices. When equipped with top, windshield, two gas headlights, oil tail lamp, gas generator, 30 by 3 tires and bulb horn, the car may be had for $495. But with electric cranking, top, windshield, two double-bulb electric headlights, electric tail lamp and horn, electric generator and storage battery, 30 by 3 1-2 inch tires, the price is $100 more.

The car has a four-cylinder, water-cooled, valve-in-the-head engine with a bore of 3 11-16 inches and a stroke of 4 inches. This is said to develop 25 horsepower, which is ample to pull the light chassis through any kind of road. Speeds from 3 to 45 or 50 miles an hour are attainable, while it is further stated that economy of fuel is another notable feature, 30 miles to the gallon of gasoline being the rule.

The engine uses rocker arms to operate the overhead valves.

The cylinder head itself is detachable, making it possible to remove pistons and connecting-rods through the top. The spark plugs are set into the head casting at an accessible angle, while the exhaust manifold is integral with this head, the outlet being through a single opening, thus eliminating back pressure.

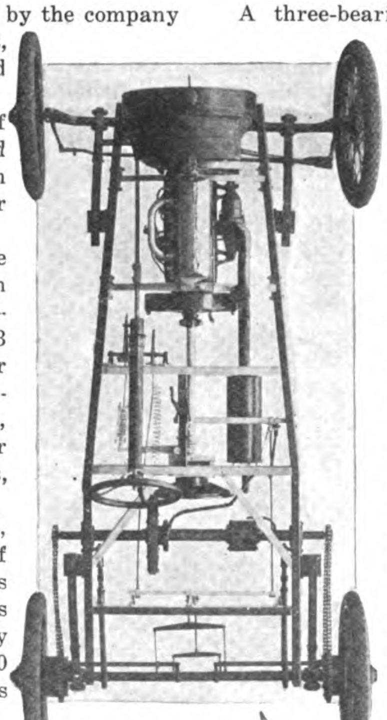
A three-bearing crankshaft, a camshaft with an equal number of supports and large valves made possible by the head construction indicate that the motor is substantially and properly designed. The valves have a clear opening of 1 1-2 inch. The principal bearings are brass backed.

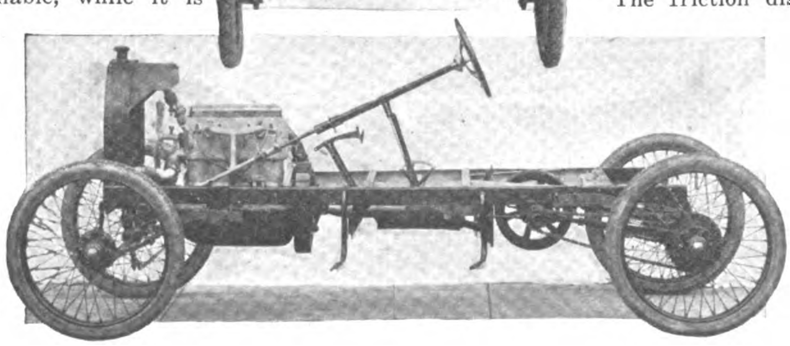
The oiling is by splash with positive pump feed, a sight feed being mounted on the dash; ignition by a high-tension system; cooling by thermo-syphon with a belt-driven fan; and a Zephyr 1-inch carbureter is used.

The motor is carried on two bowed cross pieces, front and rear, and its flywheel is not inclosed. The driving shaft runs directly from it back half way of the chassis to the friction disk transmission mechanism mounted on a frame cross member. This friction drive is of the standard type, the disk being mounted to slide on the end of the shaft so as to be brought against and released from the friction wheel which revolves at right angles to the disk. This wheel is carried on a jackshaft, from the outer ends of which chains run back to the rear axle.

The friction disk control lever is at the right of the driver, the steering wheel being on the left side. The side drive chains, running in oil, are inclosed and the rear axle to which they connect is a 2-inch tubular type. There are two sets of internal expanding brakes on rear axle drums.

Cantilever springs are used front and rear. Wire wheels are standard.

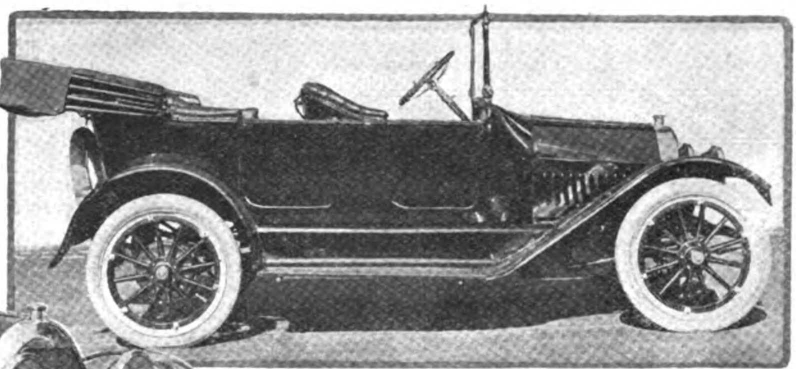


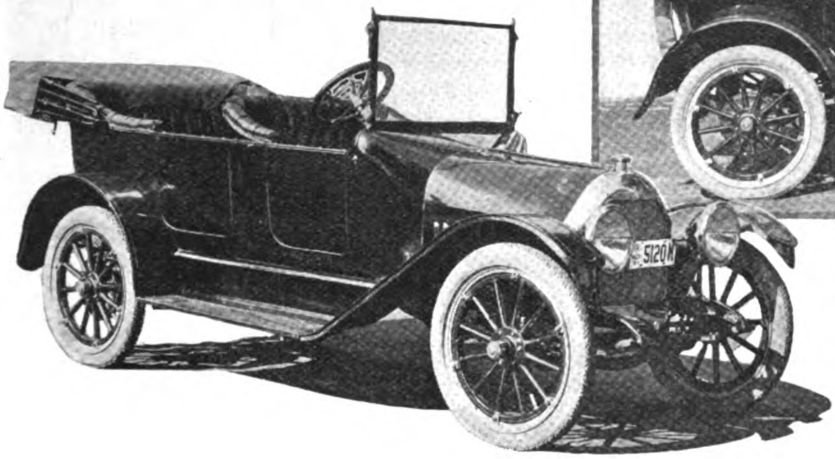


Plan and side views of the chassis which has been constructed for lightness and strength—Note friction drive

Complete Equipment Features 1915 Wahl

Streamline Body with Greater Seating Capacity — Concealed Hinges — Electric Equipment to Order





Two views of the new Wahl touring car, which has been refined for the 1915 season. Note molding of hood into body

FEATURED by more complete equipment, the new Wahl car, the product of the Wahl Motor Co. of Detroit, is now ready for delivery. The new features of the car are chiefly minor refinements and include a more up-to-date top, full streamline body with flush doors, concealed side door hinges, wider seats, deeper upholstery, roomier tonneau, double-bulb headlights, electric horn and, to order, an electric starter.

On the 112-inch wheelbase chassis there are two bodies fitted as standard, a roadster and touring car. Both sell at the same price, $890, with equipment, excluding starter and lighting system which is $125 extra. The car weighs 2,250 lbs. and is featured by a unit power plant, disk clutch, three-speed gearset with right drive and center control.

The horsepower rating of the Hazard motor is 28.5, according to the maker, and with a 3.75 by 4.5 cylinder this motor should readily turn up that amount although the S.A.E. rating is but 22.5. The construction is of unit type, the gearbox bolting through a flange to the rear of the flywheel housing, and the three-point suspension principle being carried out by having the two rear supports integral with the flywheel housing and the front support in the center. The cylinders are cast in pairs.

Valves on the Left

Being an L-head the valves are all on one side—the left. These are completely inclosed by two cover plates removable through thumb nuts. The exhaust header runs above the intake connections, and there is an individual exhaust opening from each cylinder, allowing free escape of the burned gases, while there is a common opening from each two cylinders to the intake manifold.

Crankshaft and camshaft are each carried on three bearings. The timing gears are spirally cut and of proper pitch to eliminate any noise when running at speed. One cover plate at the front when removed exposes the entire gear train for inspection or adjustment. The crankcase is of the barrel type. That is, instead of having two horizontally split halves, it is all in one piece. There is an opening at the bottom, which gives access to all bearings, however.

The oil pan which is bolted to the under side of the crankcase contains a series of four troughs which are used in connection with the splash system of lubrication. A scoop on the lower end of each connecting-rod dips into the corresponding trough on each down stroke, splashing the lubricant up into the cylinders and lubricating the walls and piston surfaces. The timing gear drive is oiled from an oil pocket of a depth sufficient to insure a sufficient quantity of oil at all times.

The carbureter is a Stromberg, while ignition is provided for by an Atwater-Kent distributer system, the unit being placed on the right side and driven by a shaft in connection with the timing gears.

Thermo-Syphon Cooling

A very efficient method of cooling by thermo-syphon is employed, which is said to be proof against over heating under any driving conditions. The large V-radiator is of Mercedes type. The fan is belt-driven.

The two-unit electrical system is a Deaco, motor and generator being separate and mounted on opposite sides of the power plant. The generator, on the right, is driven from the exposed shaft at crankshaft speed, while the starting motor is placed at the opposite rear side and connects to the teeth in the flywheel rim through an overrunning clutch. The Michigan battery used with these instruments is of 90 ampere-hours capacity and 6 volts. The system is two-wire and there are two sets of bulbs in the headlights, the smaller being for city work.

The Monocar

NOW that the postal department is extending the length of rural delivery routes from 24 to 50 miles and increasing the appropriation from $1200 to $1800 in order to permit of the use of a motor vehicle, there should be good opportunity for a small vehicle specially designed for this use. Such a vehicle could be a monocar, seating but one, and should be designed to meet all weathers.

The monocar has attracted attention abroad but has never been considered seriously in this country, in spite of the fact that some large industrial houses that provide their sales solicitors with motor vehicles are in favor of a one-seated machine as compared with a two-seated one. There are many city salesmen, in different lines, that have not any more use for a two-seated vehicle than they have for a limousine. The single-seated car is particularly suited for the work, and for city salesmen it can be made of narrower tread, which will assist in getting through traffic faster than the standard-tread machine.

The monocar for the rural free delivery man should have a narrow streamline body, so that resistance can be cut to a minimum, and weight can be held at the low-water mark. A compartment for the mail can be arranged in rear of the seat and a light, but adequate, top fitted from this compartment to the low windshield.

Getting Together

INDICATIONS point to a motor truck convention during the coming fall, in which motor truck makers and dealers will be brought together to discuss the problems that enter into the manufacture and merchandising of trucks. For the last 18 months this industry has been without any get-together conferences, and in not a few places it has suffered because of this.

Getting together, if for no other reason than becoming better acquainted with one another, is in itself sufficient reason why the makers and dealers should meet in annual conference. When a maker is left to himself for several months or perhaps a year or so, it is almost certain he will develop some action or mode of merchandising that is not in harmony with the best interests of the industry. Participation in open discussion prevents this.

There are, however, hosts of subjects that truck makers can discuss to their advantage. Some makers are opposed to conventions, because they think that nobody can tell them anything of value and that the entire convention will resolve itself into a question of a few giving away their manufacturing and merchandising secrets to the weaker ones.

Fortunately, there are few in this class. The rank and file acknowledge that there is much to be gained from a convention, and that while there may not be any revolutionizing factors unearthed, yet meeting and discussing questions in common will wipe away many of the cobwebs that have hung so long in the musty places that the owners have begun to look upon them as real enduring factors.

Merchandising problems in the truck industry will stand discussion. Not that several of the leaders in the industry are not using the most approved methods but that some of the weaker ones are not merchandising to their own advantage or to the good advertisement of the industry.

Others have been working on the installment payment policy along impossible lines.

With others the "knocking" evil has been carried so far as to react on themselves as well as injure the industry.

Others are a little dubious on the future of the industry and a true analysis of the possibilities of motor trucks would stand them in good stead.

There are those who want to know what service from the manufacture to the dealer means, and others who want to know what service from the dealer to the owner should comprise.

The possibilities of using kerosene in motor trucks and the feasibility of kerosene carbureters are today mooted questions whose clear discussion must benefit the industry.

With some the question of final drive is uppermost—whether it is to be enclosed chains, double-reduction bevels, single-reduction bevels or the worm mounted either above or below the axle.

It is not expected that a convention would give the last word on any of these subjects, but a thorough analysis would be of material interest to many in the industry.

1 Car to Every 35 Inhabitants in Bay State

Registrations of 64,717 Cars in 6 Months Exceed by More Than 2,000 the Total Licensing of 1913

BOSTON, July 11—An argument against pessimism in the motor industry is shown by the fact that in 6 months of 1914 more than 2,000 motor cars have been registered in Massachusetts, more than during the entire 12 months of 1913, and the latter was a very good year, too.

In the 6 months the Bay State has collected $16,201.18 more from automobile owners than it has in the entire 12 months of the preceding year. If the rate of increase keeps up more than 75,000 motor cars and trucks will be listed this year. And the revenue will total more than $1,000,000.

At the present rate approximately 100,000 will be operators of machines, or one in every 35 inhabitants.

Comparisons between the first 6 months of 1913 and a similar period of 1914, and also between the entire 1913 period and the first 6 months of 1914 show some interesting figures. There is not an increase in the operators and chauffeurs because each gets a license that runs for 12 months, renewable at any time. But there is an increase for the first 6 months this year over the first 6 last year in all departments except chauffeurs, the decrease there denoting that more people are driving their own cars. The figures are given in the accompanying table.

Delaware Adds 164 More Cars for June

DOVER, DEL., July 13—One hundred and sixty-four new registrations were added to the list of owners of automobiles in Delaware during June. Of this number there are fifty-eight Fords, eleven Maxwells, fifteen Overlands, seven Buicks, nine Studebakers and eight Metz cars. The rest comprise a few foreign cars and a few high-priced cars.

Colorado Exceeds 1913 by 2,000 Cars

DENVER, COLO., July 9—The total registration of motor cars thus far for 1914 is 15,340. This is a gain of more than 2,000 above the total registration for 1913, which Secretary of State Pearce estimated at 13,000.

The city and county of Denver has a registration of 6,844 for 1914 and the outside counties 8,496, as against 4,793 for Denver last year and approximately 8,000 for the outside counties. 1913 was the first year of state licensing of motor vehicles in Colorado.

The 1914 registration is divided as follows:

Total number of gasoline passenger cars	14,267
Total number of electric vehicles	708
Total number of gasoline motor trucks	272
Total number of electric motor trucks	27
Total number of steam cars	66
Total number of all classes	15,340
Number of gasoline passenger cars up to 25 horsepower	8,695
Number of gasoline passenger cars above 25 horsepower	5,572

90-Day Warranty Pasted to Car

NEW YORK CITY, July 7—The plan of pasting a copy of the N. A. C. C. standard warranty on the board which holds one of the front seat cushions, so that the warranty becomes a part of the car, has been adopted by one of the members of the National Automobile Chamber of Commerce to insure that the purchaser will receive a copy of the warranty and have plenty of opportunity to become familiar with its terms.

It has been the experience of the company that dealers do not always notify the factory of the name and addresses of new owners, so that sometimes it is impossible to place a copy of the guarantee in their hands.

Triplicate copies of the warranty are issued for each car, each bearing the serial number of the warranty and number of the car and lettered respectively A, B and C. One copy is pasted in the car, one goes to the dealer and one is retained by the manufacturer. All bear the printed facsimile signatures of the president and the secretary-treasurer of the company.

This method keeps the owner advised of his right to demand the replacement of defective parts, etc.

Jeffery Co. Fixes 23 Sales Districts

KENOSHA, WIS., July 13—A new plan of organization was announced by Sales Manager E. S. Jordan at a conference of Jeffery salesmen held at Kenosha last week.

The country has been divided into twenty-three districts, each in charge of a district representative working under the general direction of the factory sales department.

It will be the duty of the Jeffery district representative to appoint dealers, determine the extent of territories and exercise general supervision over the business of the Jeffery Co. in the districts assigned.

The appointments made with the territories designated and the headquarters of the various men are as follows:

Agent	Territory	Headquarters
C. G. Anderson	Northern Illinois	Peoria, Ill.
G. N. Bliss	Kansas and Nebraska	Kansas City, Mo.
John Carlberg	Oklahoma and Arkansas	Oklahoma City, Okla.
J. E. Corby	Indiana	Indianapolis, Ind.
A. E. Creeger	Western Ohio	Tiffin, Ohio.
C. S. Culp	New York	Rochester, N. Y.
W. H. Dailey	Southern Illinois	Kenosha, Wis.
L. H. Glenn	Western Iowa	Omaha, Neb.
H. C. Hart	Eastern Iowa	Des Moines, Iowa.
T. W. Johnston	North and South Carolina	Columbia, S. C.
E. W. Milburn	California and Nevada	San Francisco, Cal.
R. R. Minton	Colorado, Utah and Wyoming	Denver, Colo.
G. B. Muma	Montana and Canada	Winnipeg, Man., Can.
R. L. Newton	Va., E. West Va., D. C.	Richmond, Va.
L. E. Rood	Wisconsin	Kenosha, Wis.
John A. Rose	Florida and Georgia	Jacksonville, Fla.
H. D. Snyder	Michigan	Grand Rapids, Mich.
B. F. Spencer	E. Ohio, W. West Va., W. N. Y.	Warren, Ohio.
C. R. Spencer	Alabama, Mississippi and Tennessee.	Memphis, Tenn.
H. A. White	Texas and Louisiana	New Orleans, La.
W. Ross Eaton	Arizona and New Mexico	Phoenix, Ariz.
H. A. Burgess	Idaho, Washington and Oregon	Portland, Ore.

Bingham Co. To Make $800 Trucks

CLEVELAND, O., July 11—The Bingham Mfg. Co. has taken over the plant and adjoining property of the Electric Locomotive & Engineering Co., at Lorain avenue and Lake Shore Railroad, and will go into automobile manufacturing. Plans now outlined call for the manufacture of a light delivery truck to sell at about $800. Officials claim it will be the cheapest truck for its capacity made in the country. The car will have a 25-horsepower motor, 114-inch wheelbase, and its bed will be 42 by 78 by 52½ inches. It is expected to turn out about thirty cars a month at first and to increase to 100 cars a month later. The capacity is estimated at 500 cars a month.

Tabulation Showing Registrations of Automobiles, Trucks and Drivers in Massachusetts in 1914 to July

	First 6 Months of 1913 and 1914.			Total for Entire 12 Mo. of 1913, within Increase and Decrease for First 6 Mo. of 1914.	
	1913	1914	Increase	12 Mo. 1913	Inc. or Dec.

Interchangeable Wire Wheel, Packard Patent, for Kardo?

Letters of a Broad Basic Character Date Back to Early Application in 1901

WASHINGTON, D. C., July 14—What might prove to be an important addition to the group of Kardo patents was issued today. The patent covers demountable wire wheels which may be used interchangeably on the front and rear axle. It was issued to the Packard Motor Car Co. on an old application of Edward P. Cowles who was at one time employed by the Packard company in Warren, O.

This patent shows on its face that it was filed in 1912, but as it is an offshoot of an earlier application filed in 1901, its date is carried back 13 years to the early days of the automobile industry.

As may be expected from its early date, the claims are broad, covering the use of removable wheels which may be interchangeably used on the front and rear hubs, claim 7 for instance, reading as follows:

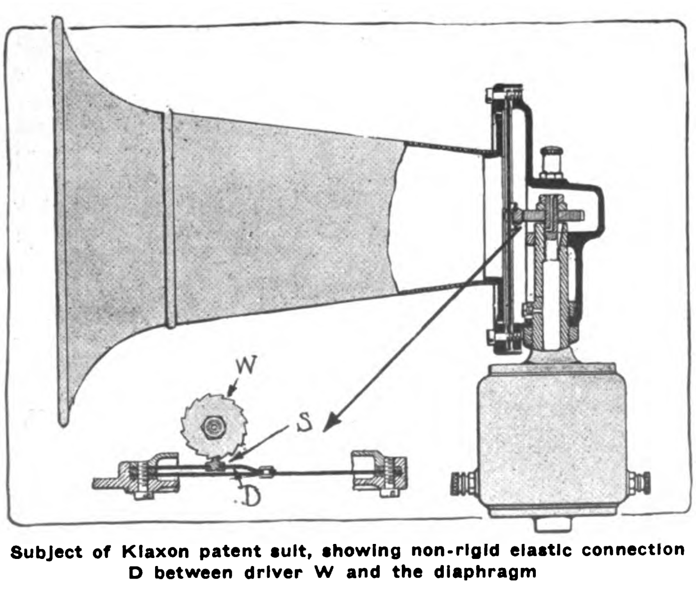
"In a motor vehicle, the combination with a front and rear stationary axle of a steering spindle pivoted at the end of the front axle, a hub-receiving member surrounding and freely rotatable upon said spindle, a driven hub-receiving member at the end of said rear axle, and wheels having hubs adapted to be removably secured, interchangeably, to said hub-receiving members."

Mr. Cowles' general idea is well expressed in his specification, where he says, "By simply removing the nuts the wheels can be interchanged, or in case of extended journeys an extra wheel carried on the carriage can be quickly and conveniently put on to replace a disabled one, without disturbing the ball or roller bearings in any way."

It is not known at the present time just what use the Packard company will make of this patent but it is reported on authority that the Kardo Co. will take it over to use in connection with the axle patents which it acquired recently from the Packard, the Peerless, and the American Ball Bearing companies.

Protest Against Truck Demonstration Tax

NEW YORK CITY, July 11—A protest against the demonstration tax now imposed upon motor truck dealers in this city has been lodged by the various dealers in this city with the Merchants' Assn. Manufacturers of and dealers in automobiles are required by the Callan automobile law to take out a general license which covers all of their vehicles prior to sale, such vehicles being identified by a single license number. But these vehicles are not allowed to be used for hire for private use. It is, however, necessary, particularly in the case of motor trucks, to demonstrate the capacity of the truck before a sale can be made. These demonstrations often show the truck in operation under the same conditions as it would be used by the owner.



Subject of Klaxon patent suit, showing non-rigid elastic connection D between driver W and the diaphragm

The Automobile Bureau of the Secretary of State's office holds that demonstrations with loads is a violation of the requirements of the law and demands that the manufacturers in such cases take out owners' licenses for these demonstrating trucks. This would compel the payment by the manufacturers in some cases of several thousand dollars annually for license fees.

The failure to comply with this law, that is, the taking out of both an owner's license and also a general license required of the manufacturers, makes the driver liable to arrest and fine.

Simms Spark Plug Patent Valid

DETROIT, MICH., July 11—In the case of the Frontier Specialty Co. against the Heinze Electric Co. for infringement of Simms Patent 642,167 covering a priming spark plug construction, final decree has been entered in favor of the complainant. The Court held that the patent is good and valid as is the title of the complainant and that the defendant infringed claims 1 to 6 inclusive and the defendant has been enjoined from further infringement of the patent. All question of damages, etc., has been settled.

Cadillac 2-Speed Axles Not Enjoined

DETROIT, MICH., July 10—Judge Sessions of the United States court, in Grand Rapids, Mich., refused to grant an injunction against the Cadillac Motor Car Co., Detroit, from continuing to make any more two-speed axles, as had been applied for by W. S. Austin, the Grand Rapids automobile manufacturer. The case will come up for final hearing August 11.

Weed Company Gets Default Order

NEW YORK CITY, July 13—In the case of the Parsons Non-Skid Co. and the Weed Chain Tire Grip Co. against the Leather Tire Goods Co., Inc., no answer was filed by the defendant in 20 days after the serving of the notice. Judge Hand has signed an order taking the bill of complaint pro confesso. The motion was made by Frederick S. Duncan, attorney for the complainants. The court ordered that the bill be taken pro confesso, "and that after the expiration of 30 days after the entry of this order a final decree may be entered herein."

A preliminary injunction on default was issued by Judge Mayer in favor of the Parsons Non-Skid Co. and the Weed Chain Tire Grip Co. in May in the U. S. District Court for the Southern District of New York.

The plaintiffs charge infringements on the Parsons patent No. 723,999, covering the well known Weed chain tire grip construction.

Klaxon Sues Newtone Dealer

NEW YORK CITY, July 13—The Lovell-McConnell Mfg. Co., Newark, N. J., has brought suit against Julius Bindrim, a Brooklyn dealer in automobile supplies selling Newtone and Newtone Superior horns. The plaintiffs allege infringement of patent No. 1,094,403, granted April 21, 1914, and covering a non-rigid elastic connection or coupling between the driver and diaphragm of an automobile horn, as shown at D in the illustration. The driving wheel is shown at W and the stirrup at S. These improvements are intended to render the sound less harsh and at the same time to reduce the wear and tear on the diaphragm. The Newtone and Newtone Superior horns referred to are models put upon the market since the beginning of the suit of the Lovell-McConnell company against the Automobile Supply Mfg. Co.

The Automobile Supply Mfg. Co. is defending the suit against Bindrim in the same manner in which it has defended all suits brought against its dealers.

Fined for Speeding—Appeals—Wins

NEW YORK CITY, July 14—The first speeding case to be tried in this city by a jury has resulted in a victory for an automobile owner and it only took the jury five minutes to acquit him after the magistrate had fined him $50.

Silas Axtell, an attorney, was the defendant. It seems that the whole case revolved around the question, whether going 18 miles an hour at 10 o'clock at night when the street was empty of any traffic was really breaking the law. The officer claimed he was going 26 miles an hour. Mr. Axtell proved he was going 18 miles an hour. The magistrate then fined him $50 for exceeding a speed law of 15 miles an hour in the crowded section of the city, with the permission of an appeal. Mr. Axtell's evidence that the street was practically empty of any traffic, was ruled out.

The appeal came yesterday before Judge Crain in General Sessions and the owner was acquitted. The judge stated that a speed of 15 to 20 miles an hour is safe when the streets are not crowded and when the driving is not reckless. The same testimony heard by the magistrate went before the jury. The ordinance involved:

1. Rates of Speed—No person shall operate, drive or propel, and no owner thereof riding thereon or therein shall cause or permit to be operated, driven or propelled, on any public highway in the city of New York, any motor vehicle recklessly or negligently, or at a speed or in a manner so as to endanger, or to be likely to endanger, the life or limb or property of any person, provided, that a rate of speed exceeding 15 miles an hour shall constitute prima facie evidence of a rate of speed and manner of driving prohibited as aforesaid and of a violation of the provisions of this section; provided further, that a rate of speed exceeding 20 miles per hour shall constitute a rate of speed and manner of driving prohibited as aforesaid and in violation of the provisions of this section; provided further, however, that a rate of speed exceeding 25 miles per hour on public highways where the same pass through country or outlying sections which are substantially undeveloped and sparsely settled, shall constitute a rate of speed and manner of driving prohibited as aforesaid and in violation of the provisions of this section.

This ordinance which became effective June 1, 1913, gives persons driving automobiles the privilege to travel the streets of New York at the rate of 20 miles per hour, but, in the unusual language of the ordinance, if the speed exceeds 15 miles it will constitute prima facie evidence of recklessness or negligence.

—

WASHINGTON, D. C., July 9—A drawback allowance was today granted by the treasury department on the exportation of automobile windshields manufactured by the Diamond Mfg. Co., Detroit, Mich., with the use of imported glass.

—

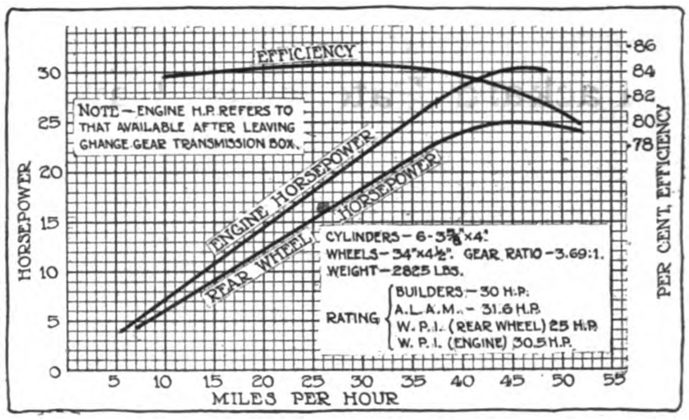
Stewart-Warner Charges Patent Infringement

CHICAGO, ILL., July 13—Suit has been brought in the United States District Court by the Stewart-Warner Speedometer Corp., Chicago, against the National Carbon Co., Cleveland, for alleged infringement of a Stewart magnetic-type speedometer. This is an amendment to the original bill filed a few months ago against the American Eveready Co., New York with offices in this city. The American Eveready Co. and the National Carbon Co. have consolidated and the Chicago branch, now called the American Eveready Works of the National Carbon Co., was the original defendant. The American Eveready Co. states that it will fight the case.

—

Ball Bearings in Customs Auction

CLEVELAND, O., July 9—Eleven cases of ball bearings will be sold at public auction on August 11, 1914, at the Custom House, this city, at 10:30 A. M. The cartons containing the balls are printed, "Best Quality Diamond Cast Steel Balls," manufactured by the Auto Machinery Co., Ltd., Coventry,



Curves showing the results of a test on the efficiency of the Franklin 6-30

England. The dutiable value is $4,070. The duty at 35 per cent. is $1,424.50 and the home value is $5,494.50. A detailed description of this merchandise can be obtained at Room 214, Federal Building, Cleveland. Samples will be forwarded to the collector of customs in the cities of those interested.

—

Detroit Section of E. V. A. A. Organized

DETROIT, MICH., July 9—For the purpose of further promoting the popularity of electric vehicles, both for pleasure and for commercial usage, a Detroit section of the Electric Vehicle Association of America has been formed, of which J. W. Brennan, purchasing agent of the Edison Illuminating Company, Detroit, is temporary chairman.

—

Franklin Shows 84.4 Per Cent. Efficiency

WORCESTER, MASS., July 8—Final reports of a test on the Franklin 6-30 chassis held in the automobile testing plant of the Worcester Polytechnic Institute of this city show an average efficiency of 84.4 per cent. in the power transmission of the car at ordinary driving speeds.

In making the test the car was run on direct gear. The rear wheels rested on steel drums which were connected to water brakes which absorbed and measured the power. In this way a reading was secured on the power that would be available for driving the car along the road at any given speed. Readings were taken at car speeds of from 5 to 50 miles an hour and the results plotted in the curve shown herewith.

The efficiency given is the ratio of the power delivered at the wheels to that delivered by the engine. Thus at 35 miles an hour if the motor is delivering 25.5 horsepower and the wheels are delivering 21.5 the car is 84.4 per cent. efficient and 15.6 per cent. is being lost in tire friction, slippage and internal losses such as bearing friction, etc. The results of the test are certified by the Institute.

Bosch Buys Rushmore Interests

NEW YORK CITY, July 8—The Bosch Magneto Company has bought the plants and the entire business of the Rushmore Dynamo Works, of Plainfield, N. J. The completion of this deal, which has been pending for some months, now gives the Bosch company two factories in which to carry out the combined business of the merger.

All the contracts and service obligations of the former Rushmore company will be carried on, and it is the present intention to carry on the Rushmore line as it was before the combination took place, with such refinements and additions as time may suggest. The Plainfield plant has a floor space of 100,000 square feet and at the present time employs a force of about 700 men. This, added to the Springfield plant of the Bosch company, practically doubles the facilities for manufacturing and now puts the Bosch company in a position to accept orders for any quantity of the full line of electric lighting and starting systems which will be manufactured.

The line of starting and lighting products which was formerly known as the Rushmore will now bear the name of Bosch-Rushmore, while the other Bosch products will still carry the name Bosch as heretofore. The government work in searchlights, etc., will also be continued.

While the manufacturing end of the Rushmore line will continue much as it was under the direction of Bosch officers, the sales and service work will be handled through the Bosch organization. The 239 service stations that have been built up by the Bosch company will now take care of the service work for the entire business. Victor Kliesrath, as chief engineer, and C. M. Wills, as factory superintendent, will supervise the work under their jurisdiction in both plants of the company.

The Rushmore company has been established for over 20 years, having specialized during that time in the production of dynamos for train lighting and arc lights. They became interested in the automobile lighting problem at an early date and then finally in the production of an electric starter. This full line, which was described in THE AUTOMOBILE for November 6, 1913, and augmented by another light starting motor, as described in the issue of May 14, will be continued. In addition, the Bosch company is manufacturing a starting and lighting system of their own. Both the Bosch and Bosch-Rushmore systems operate at 12 volts. The Bosch starting motor uses an over-running clutch and the Bosch-Rushmore a flywheel installation.

Detroit Dealers Move 12,500 Cars in 1914

No Indication of Depression in Contiguous Region—Business Generally Better

DETROIT, MICH., July 14—Detroit automobile dealers have sold during the first 6 months of this year approximately 12,436 automobiles. Eighteen of the local dealers, by their own figures, have sold 10,236 machines, and adding to this the estimate of 1200 machines sold by dealers who have not given their definite figures gives the total of 12,436.

It does not mean that this number of automobiles have been sold in Detroit and vicinity, as some of the dealers have practically all of the State of Michigan. Others have but a few counties.

In general, business this year has been much better with Detroit dealers than a year ago, in spite of the depression due to general financial conditions and that brought about by the Mexican war. Ninety-five per cent. of the Detroit dealers state they have had a better year during the first 6 months of this season than during the corresponding 6 months of 1913. The remaining 5 per cent. are not optimistic.

Practically all of the dealers are looking forward to good business for 1915, some of them having already booked large orders. Nearly half of the dealers this year experienced a shortage of cars at one time or another, and with some of them the shortage during the months of May and June was an important factor.

The following extracts from individual reports of the different companies show the general tendency of business during the first six months of the year:

Buick—Business for the first 3 months of this year was 100 per cent. better than for the 6 months a year ago. We were sold out by March 16. Since then we have turned down 316 orders. We have already booked orders for 136 1915 cars.—C. C. Starkweather, Branch Manager.

Car-Nation and Keeton—We started delivering the little Car-Nation light cars only the latter part of April and have sold several hundred, while the sales of the high-priced Keeton have been most satisfactory. The general outlook is very good—Lininger-McHugh Co.

Cartercar—Our records show 25 per cent. increase over corresponding period a year ago. Have hardly been able to get cars during last 3 months.—L. Williams.

Chalmers, Pierce-Arrow, R. & L.—Business increase 25 per cent. over a year ago. Demand for cars very strong during last month. —Neumann, Lane Co.

Chevrolet—Have done 50 per cent. better business than a year ago.—Chevrolet Motor Co.

Detroiter—Business is good, but there has been general unrest so that a high mark in sales has not been reached. Conditions are beginning to look better.

Ford Business Gains 60 Per Cent.

Ford—Business 60 per cent. better than 1913. June has been our best month, and is 100 per cent. above last year. Have sold 5,200 cars, or 2,200 more than same period last year. Our territory is entire state of Michigan, less five counties around Grand Rapids and the upper peninsula.—Ford Motor Co. Detroit Branch.

Grant—From March to July 1 have sold 165 cars. Conditions are improving and 1915 will be a big year.—Geo. C. Waite.

Hudson—Business 100 per cent. better than in 1913. Have 1915 models on hand and getting splendid business.—E. Bemb, Bemb-Robinson Co.

Hupmobile—Business 40 to 45 per cent. better than last year. Have not felt so-called business depression.—Grasser Motor Car Co.

Krit—During first 6 months of this year have sold only five less cars than during the preceding 14 months. We handle Detroit and Wayne County only. Business 50 per cent. better than last year.—H. L. Davies.

Lozier and Paige—From May 1 to July 1 have sold 100 more cars than a year ago during same period. On one model we are twenty-five cars behind deliveries now.—Wetmore-Quinn Co.

Maxwell 100 Per Cent. Ahead of 1913

Maxwell—Have sold close to 700 cars during first half of 1914, which represents an increase of 100 per cent. over last year, and could have increased our business 150 per cent. if we could have obtained cars. For last three months have been shy 100 cars per month in deliveries.—Cunningham Auto Co.

Oakland—Business 20 per cent. better than first 6 months of last year. Could have sold 40 or 50 more cars up to July 1 if we could have had them. Our territory, Wayne County only.—Detroit Oakland Branch.

Oldsmobile—Have disposed of 25 per cent. more cars than last year. Outlook for 1915 good.—Detroit Oldsmobile Branch.

Overland—Have sold a few less than 600 cars, and of these 60 per cent. right in Detroit. Business 100 per cent. better than a year ago. Our territory only five counties in state. During last 2 months we did $200,000 worth of business.—Overland Motor Car Co.

Packard—Business satisfactory as it has always been.—Standard Auto Co.

Couldn't Get Enough Cars

Reo and Mitchell—Have never had a better year than 1914 so far, having sold 600 cars in the Reo territory of nine and one-half counties, and the Mitchell in one-half the state. Three-quarters of our sales were made in Detroit and Wayne County. This business would have been 50 per cent. bigger if we had had the cars to sell. Our records show that in June we could have sold 200 more cars. Business 65 per cent. ahead of last year.—M. A. Young.

Saxon—In 4 months have sold 400 cars. Could have sold 200 more if we could have gotten them.—T. J. Doyle.

Business Never So Good—Studebaker

Studebaker—During the 8 years I have been in the automobile business, business has never been as good as this year. We have done close to 30 per cent. better during the first half of 1914 than during the corresponding 6 months of 1913. During the last 3 or 4 weeks we could not get another four and thus lost about 120 to 125 sales in less than one month. The business in sixes has been nothing short of surprising. I think the outlook for the future business has never been better and estimate that

Market Reports for the Week

MARKET prices in general remained constant this week. A weaker tone in a few of the metal products developed. Both electrolytic and Lake copper dropped in prices, due to a small demand. Tin had a fluctuating week of it. Rising to $32.60 on Friday, it suddenly broke, closing on Tuesday at $31.50 per 100 pounds. This reduction in price was in sympathy with that in London, which occurred on the same day. There was very little demand from either consumers or speculators. Prices were generally steady in the oils and lubricants market. Cottonseed oil went up $.09 per barrel due to brisk trading conditions. The rubber market in this city was firmer this week, especially for plantation. Fine Up-River Para rose $.01.

1915 will be the biggest year we ever had. Conditions are good all over the state, the increasing sales coming from all over and no one particular section of Michigan.—Sales Manager Detroit Studebaker Branch.

Winton—Business 50 per cent. ahead of last year. Were sold out May 18. Business for 1915 is 100 per cent. ahead of the business of a year ago.—Winton Detroit Branch.

New Federal Factories To Cost $500,000

MILWAUKEE, WIS., July 13—Officials of the Federal Rubber Mfg. Co. celebrated the third anniversary of the company's existence on July 1, by giving orders for the erection of new factory buildings to cost over $500,000. Work is already under way on the new structures. When completed the new buildings will mean an increase of 150,000 square feet of floor space, making 450,000 square feet in the entire factory. There are 1,500 employees on the Federal payroll, More men will be employed as soon as the additional factory space is available.

Superintendent Hutchens is already at work on the buildings for 1915. These will consist of a separate building 60 feet by 497 feet with six stories and basement to four of the present buildings—all 50 by 50 feet and five stories in height. Brick and mill construction will be used throughout, this having been found to be the most desirable for purposes of rubber manufacture. Among the buildings on which work has been started is the addition to the power plant. This will contain two new boilers of the latest water tube type, capable of delivering 1,000 horsepower to the dynamos. Overhead coal bunkers will be arranged in such manner as to eliminate the handling of fuel by employees from the time it leaves the freight car until it enters the automatic stokers at the base of the furnace. These coal bunkers will be 700 tons capacity.

In addition to new boilers, a 1,000-kilowatt low pressure, exhaust steam turbine will be installed. This will be directly connected to three wire current direct generator with jet condenser and cooling tower. This will increase the electric power generated formerly by one-third. Enough space will be provided in the new building to take care of one more of the big turbines, which will probably be installed during the coming year.

Superintendent Hutchens estimates that over $1,000,000 has been expended in new machinery and buildings in the past 3 years. Of the 8 acres owned by the Federal company, 6½ acres are covered with buildings, and a big portion of the remainder will be placed under roof by the end of next season.

Overland Plans 75,000 Cars for Next Year

LONDON, ENGLAND, July 10—John R. Willys, president of the Willys-Overland Co., is quoted as saying that he expects to turn out 75,000 automobiles from the factories of his company during the next 12 months. Last year, he said, the company manufactured 45,000 cars. Mr. Willys also stated that the company expects to ship 7,500 automobiles to Europe next year.

Automobile Securities Quotations

NEW YORK CITY, July 15—The continued inactivity which has marked the automobile and allied securities market for several weeks has been apparent throughout the past 7 days. There were very few changes recorded, most of the stocks remaining at the same level as last week. Case gained 2 points. Firestone Tire 5, Goodyear 4 on the common and 1 on the preferred, Maxwell common gained ¼ point, Stewart, Warner common ¾ of a point, Studebaker common 1½ and preferred 2 points. The only other gains recorded were U. S. Rubber first preferred ½ point and Willys-Overland common 1 point. The losses suffered were very slight. The complete quotations for the past week follow:

Gasoline Prices Are Still Tumbling

Competition and a Reaction in the Crude Oil Market Among Contributing Factors

NEW YORK CITY, July 14—Gasoline prices throughout the country are getting lower. However, every reduction in the price of gasoline is not the result of competition alone. The recent reaction in the crude oil market had a great bearing on the lowering of these prices and not nearly so much price cutting would have been done had this not happened. However, the biggest reductions in prices have come where most competition is offered. The following list gives the prices in different sections of the country:

New York City	$0.23	St. Louis, Mo.	$0.11
Los Angeles, Cal.	.12	Jersey City, N. J.	.09
Detroit, Mich.	.11	Dallas, Tex.	.08

Conditions in this city have kept the prices a little higher than in the surrounding country. Since the beginning of July, New York garage owners have generally reduced the price of gasoline from $.25 to $.22 and $.23 a gallon, and it is likely that further reductions will be made in the near future.

The initial step in reducing prices was taken at a meeting of garage owners, started by the West Side Garage Owners' Assn., last week. Arrangements are now progressing towards the holding of another meeting of the garage men to effect a reorganization in the garage business. Under existing conditions the cost of car storage generally charged by the garage does not cover expenses. In order to make a profit the garage owners kept up the price of gasoline. Until the recent cut in prices was effected, the New York garages were paying $.14 a gallon for their gasoline and retailing it at $.25. To equalize conditions, it is proposed to raise the storage charges and lower the price of gasoline. It is thought that in this way it will be possible to bring the price of gasoline at the garages below $.20 a gallon.

The strongest competition in the East is found in Hudson county, N. J., across the Hudson from New York City, where gasoline can be bought as low as $.09 a gallon. Most of the gasoline in that territory is supplied by the Standard Oil Co. of New Jersey, Gulf Refining Co., and the Texas Co.

In the South gasoline prices are lower than they have been for a long period. In Texas gasoline is being sold to the dealers in some instances as low as $.08 a gallon.

In the middle West gasoline is sold below $.11, more frequently in Missouri.

In California several cuts in gasoline prices have recently been announced by the Standard Oil Co. of California, and these have been followed by the other companies.

3,256 Cars and Trucks Exported in May

WASHINGTON, D. C., July 15—*Special Telegram*—Ninety-nine commercial cars valued at $127,024 and 3,157 passenger cars valued at $2,857,601 were exported in May, as against 141 commercial cars valued at $236,383, and 2,895 passenger cars, valued at $2,918,806, exported in May a year ago. During the 11 months' period ended May the exports were 694 commercial cars, value $1,061,354 and 26,324 passenger cars, value $23,522,081 in 1914, and 878 commercial cars, value $1,569,750 and 22,254 passenger cars, value $22,252,032 in 1913. Our best customer in May was Canada, which imported 764 cars, valued at $941,345. United Kingdom was second with 663 cars, valued at $556,753, and British Oceania, third with 466 cars, valued at $416,259.

Charge Stock Issuance Fraud by U. S. L. Directors

BUFFALO, N. Y., July 14—Judge Hazel in federal district court Monday afternoon named James O. Moore of Buffalo, Guy M. Walker of New York City and A. Henry Ackerman of Brooklyn, N. Y., as receivers for the United States Light & Heating Co., directing them to continue business of the concern. The court fixed a joint bond of $100,000 for the three receivers. Mr. Ackerman is at present manager of the Niagara Falls plant of the company.

Alleging that in the past 5 years directors of the United States Light & Heating Co., a Maine corporation, with a plant here in Buffalo, issued in an illegal manner $9,500,000 worth of stock, several petitioners in United States district court added to their application for the appointment of a receiver charges of fraud and mismanagement. Issuing of stock in five particular cases is claimed by the petitioners and complainants as having been in violation of the law.

The stock issued to William Hawley, a director of New York, said to be worth $100,000, is alleged a fraud, stock reported worth $10,000 awarded to Sanford Adler of New York is cited in bill of complaint as being fraudulent and also the reported issuing of stock said to be worth $100,000 to J. Allen Smith of New York, at the time of the transaction vice-president of the company, and Charles A. Starbuck chairman of the directors. The issuing of stock to Edmond Hooley, inventor, of Niagara Falls, in exchange for patent rights secured by the inventor is illegal according to the complainants because the stock, they maintain, was worthless. The petitioners for appointment of a receiver by the court and complainants in an action to determine whether or not the affairs of the company were mismanaged and the directors guilty of fraud and illegal operations in office are the Picher Lead Company, Joplin, Missouri; the Buffalo Drill Company and Frederick R. Humpage, of 22 Bidwell Parkway, former head here of the E. R. Thomas Motor Car Company, creditors and stockholders and certain associate creditors and stockholders.

The directors of the company, some of whom are liable to face prosecution in the event that the petitioning creditors establish proof in their contentions of fraud and illegal practices, and William Hawley, Walter S. Crandall, Charles A. Starbuck, J. Allen Smith, Theodore P. Shonts and John A. Fleicher.

Since the first of the present year the affairs of the company have been satisfactorily carried on by Frederick R. Humpage of Buffalo and Guy M. Walker and J. A. Fleicher of New York City as a stockholders' committee. The petitioning creditors do not desire that the factories of the United States Light & Heating Company be closed down, and in court yesterday afternoon they offered in eivdence contracts to show that considerable business is offered the plant and that money perhaps sufficient to meet all obligations can be secured within the next several months.

What the petitioners maintain they do want is a thorough review of the operations of every defendant in the actions and an adjustment of the company's affairs. The concern claims assets of $3,000,000 with reported liabilities of $900,000. The plant and main offices of the company are located in Niagara Falls, and during the absence of J. Allen Smith, vice-president and general manager, who now is in Europe, the concern has been managed by Henry Ackerman, Buffalo, who in conjunction with the stockholders' committee has profitably run the business during the past few months.

Through the complaint filed by Frederick Humpage it was shown where various alleged fictitious stockholders' claims had been made by stockholders and large and exorbitant sums had been transferred to their personal use. Another important factor in the case is the fact that through John A. Fleicher, a stockholder in the company, the famous Brady estate of New York, is interested to the extent of several thousands of dollars.

Counsel for the company announced today that it will contest the receivership in the courts. The statement made advances the claim that to bring about the receivership it was necessary that the company receive preliminary notice and that no such notice was given.

Billings & Spencer To Increase Force

HARTFORD, CONN., July 10—Satisfaction is keen in local industrial circles now that the Billings & Spencer Co. has taken over the plant of the Columbia Motor Car Co., which has been closed down for some time past and dismantled of mechanical equipment. The Billings & Spencer Co., one of the soundest of the old line local industries took immediate possession. It is said an increase in the working force will result from the purchase. During the slack period with the former owners work was done in the shop for Billings & Spencer. The company has outgrown its present quarters. The transfer of the business to the new possession will be made gradually. In this way there will be no interruption in the work at the old plant. The Billings & Spencer company's progress has been consistent with the expansion of the automobile industry. With the new purchase there is ample room for expansion as the tract comprises over eight acres and furthermore shipping facilities are infinitely better at the new location as spur tracks from the main line of the New York, New Haven & Hartford road run into the factory yard and buildings. Automobile forgings constitute a big share of the company's product and most of these are shipped to the middle western manufacturers of cars. The company manufactures 23 different kinds of wrenches and in specializing on forged automobile accessories.

Quantity Production Means Cyclecar Success

By Hon. Mitchell May, Secretary of State

AN interesting phenomenon of the last year or so is the development of a motor vehicle intermediate between the motorcycle and the ordinary motor car. The name cyclecar has been invented for this hybrid machine; and it is a name that should stay, since it embodies the two principles upon which the vehicles are made,—viz., that they chiefly resemble motor cars so far as the body is concerned and motorcycles in respect to the chassis. The difference between a motorcycle and a motor car has never been legally defined in this state, but custom regards as motorcycles all motor vehicles having three wheels or less. The four-wheeled cyclecar is always a motor car, whereas the three-wheeled one might or might not be.

Big Makers Would Help

The cyclecar is still in its infancy and it is not without interest to consider at this early stage its probable line of development. There are a number now in use; some with seats arranged in tandem and some abreast and with every form of gearing and transmission. So far, the output has been from the small maker rather than from the large motor car manufacturers. The latter are at present busy with the usual form of motor vehicle, and are little under pecuniary temptation to turn their activities into a new channel. There is no doubt that the large manufacturers would be able, if they took up the cyclecar, not only to improve it greatly, but even to introduce some of its simple features into the smaller motor cars. At present, the motor car is changing very little. The influence of cyclecar design bringing with it fresh ideas, should, therefore, be good. It will inevitably suggest here and there alternative ways of doing things which have too long been stereotyped. Precisely just what effects will be produced in this way, it would be impossible to predict, but a useful stimulus may be looked for.

Hon. Mitchell May, secretary of state of New York

The cyclecar is the direct descendant of the motorcycle and side car, just as the latter sprang from the bicycle. The effort needed for propulsion of the bicycle was too wearing to allow the combination to become popular. With mechanical power this objection vanished. A cyclecar chassis is much more lightly built than motor car chassis; besides, the steering is far more simple. Some designs are on the market for $400 and there is no reason why they should not become cheaper. With proper encouragement, the cyclecar should prove an exceedingly effective way of making motoring still more popular, particularly as a means of vacation touring. At present there are not many cyclecars in use in this state, but when there is introduced a cheap, reliable vehicle costing less than a motor car does now, and capable of carrying two persons and their luggage, the movement may be expected to grow until the production of cyclecars becomes one of the greatest industries in the country. So far, the great motor car manufacturers have stood aloof and it is not to be expected that much will be seen of the cyclecar during the present year. But a great field of possibilities awaits the maker whenever the demand tempts him to take advantage of the possibilities.

Price Is the Main Factor

However, the whole question of cyclecars revolves itself into one of price and, as manufacturers have already shown that cars of moderate power can be marketed at an exceedingly low figure, when turned out in sufficient quantities, the most probable solution of the cyclecar problem seems to be in a similar direction. But the question of relative comfort is sure to be the final criterion by which choice will be made. Great as have been the strides in motorcycle and side car constructions, in the shape of greater trustworthiness and increased comfort for both rider and passenger there is no doubt that many people regard the combination with distrust on account of the apparently exposed position of the rider and the cramped position of the passenger. The degree of comfort obtainable in a cyclecar depends on the amount of attention the makers are willing to bestow upon the springing and as soon as they realize that the buyer of a motor car does not care to be too crowded, a very great improvement will result. With the light weight which is characteristic of the cyclecar the designers should be able to construct good suspensions.

French Army Testing Trucks; 112 Compete for Subsidies

Rigorous Road Trials from July 6 to August 4 Begin and End with Examinations

PARIS, FRANCE, July 9—In this year's French military commercial vehicle trials to determine the type of trucks suitable for government subsidies, there are 112 entries, constituting the biggest number of commercial vehicles ever brought together for a competition in France. The event opened on June 29 with examination and verification of the competing machines. The trucks took the road on July 6 and with the exception of 3 rest days will be kept constantly on the move until the evening of August 4, when the survivors are submitted to a close technical examination. Going back to a previously tried system, the trucks are run over a varied set of roads around Versailles, returning to this town each evening. As Versailles is practically a suburb of Paris, and within a dozen miles of the great majority of the French factories, the choice of this centre is pleasing to manufacturers.

This year's trials differ from those of last year by the admission of tractors in addition to ordinary trucks. The four wheel drive machine is a type now being seriously encouraged by the army and likely to have a considerable application for commercial purposes. All the firms taking part in the trials are French, as required by the rules. The list is as follows, each firm entering from 2 to 8 trucks of different types: Berliet, Renault, Dewald, Clement-Bayard, Delaugere-Clayette, Cottin & Desgouttes, Blum, Rochet-Schneider, Barron & Vialle, Panhard & Levassor, La Buire, Peugeot, Aries, Saurer, Mors, Balachowsky & Caire, Schneider, De Dion Bouton, and Delahaye.

Results Out in French 4-Wheel Drive Tests

PARIS, FRANCE, July 9—After considerable delay, the official results have been published of the military four-wheel drive tractor competition held by the French army last March. This event, the first of its kind, took place across country and over military roads in the east of France, during which the machines were put to a particularly severe test, and was followed by a very close technical examination in the artillery headquarters at Vincennes, near Paris. In the following list merit points have been awarded for regularity of operation, hill climbing ability, economy in fuel and oil, and finally for the state of the mechanism at the end of the tests.

LIGHT TRACTORS

		Points
1	Latil No. 9	810.7
2	Panhard No. 2 (Knight motor)	773.6
3	Panhard No. 1 (Knight motor)	743.6

Sixteen Entries for Elgin Races

CHICAGO, ILL., July 14—One new entry for the Elgin road races of August 21-22 has been filed within the past week—that of Charles Erbstein's second Marmon, which will be driven by Lou Heinemann.

Eight cars are already nominated for both days, making a total of sixteen for the meet. These include E. J. Schroeder's Peugeot, E. V. Rickenbacher's Duesenberg, Oldfield's and Anderson's Stutzes, Grant's and Babcock's Sunbeams, and Patschke's Marmon. The Chicago Automobile Club is counting on six cars from the Moross group, including Tetzlaff, Hughes and Calson in Maxwells, Klein in the King, Brock in the Ray, and d'Alene in a Marmon. Spencer Wishart and Ed Pullen in Mercers are promised, and Finley Porter is rushing work on his new cars in order to start three of them at Elgin.

Bob Burman has promised positively to drive his Peugeot both days, and it is almost certain that Mulford will be here with a third Peugeot. Alex Sloan is figuring on starting two Cases, and Knipper in a National is another probability. De Palma, too, can be counted on as a certain starter, but it is not known which he will drive, a Mercedes or a Vauxhall. Two more Duesenbergs will be nominated, while there are probably a dozen other likely candidates.

An extra $1000 has been added to the prize money, making first each day worth $2000; second $700 and third $300. Harry Vissering, president of the Chicago Automobile Club, already has given $200 for the fastest lap the second day, while the first day is taken care of by Martin Kavanaugh, also a club member, who hangs up $200 for the first day.

Grand Prix Mercedes for Next Vanderbilt Race

NEW YORK CITY, July 11—One of the three Mercedes that took first, second and third place in the Grand Prix of France on July 4 will probably be a contender in the next Vanderbilt Cup race.

Paul Lacroix, the American agent for the Mercedes, has received instructions from E. J. Schroeder, owner of the Mercedes car which won the two last Vanderbilt cup races, to enter into negotiations with the Mercedes factory to obtain for him one of the Grand Prix racers, which Mr. Schroeder intends to compete with in the next Vanderbilt and Grand Prix races in California and the next Indianapolis 500-mile race.

It is probable that Ralph De Palma will drive this car in the three events, but if he is not secured it is most likely that either Lautenschlager, Wagner or Salzer will come over to drive in the races.

It is expected that one of these cars will be here before long. De Palma is now abroad expecting to conclude arrangements with the Mercedes factory to bring one over for the Elgin road race, where it will be entered by E. C. Patterson.

$4,650 in Prizes at Galveston Races

GALVESTON, TEX., July 10—Sixteen events are announced for the next big automobile race meet—the Galveston Beach Carnival, scheduled for July 30-31 and August 1 and 3. Events for all classes of racing cars are on the program and $4,650 in cash prizes is offered, together with numerous valuable trophies. An innovation this year will be a day devoted to amateur races exclusively.

Parade To Dedicate 1915 Motor Exposition

SAN FRANCISCO, CAL., July 7—A line of 25,000 automobiles, the largest number of cars ever brought together at one time in the United States, is expected for the 50-mile parade during the Automobile Day Festival of the Panama-Pacific International Exposition on July 15.

This important event will signalize the dedication of the space to be devoted to automobile exhibits at the exposition. Upon the conclusion of the parade, which will terminate upon the exposition grounds, the area set aside for automobile exhibits will be turned over to the automobile industry by Captain Asher Carter Baker, U. S. N., retired, director of the Division of Exhibits.

Tented Motor Show at Indiana Fair

INDIANAPOLIS, IND., July 13—The fall motor show, to be held at the Indiana State Fair here the week beginning September 7, promises to eclipse any motor show ever given by the Indianapolis Automobile Trade Association, under whose auspices it is to be held. The committee in charge of the show consists of Fred I. Willis, of the Hearsey-Willis Co.; George D. Wildhack, general traveler for the Oakland Motor Car Co., and John Orman, of the Premier Motor Manufacturing Co.

A tent 150 feet wide and 325 feet long is to be used. This will give 20,300 square feet of exhibiting space, exclusive of

Lining up for Montamarathon trophy race at Tacoma, July 4 aisles. It will be located on a prominent part of the fair grounds, near the Coliseum. Until August 22 space will be sold at ten cents a square foot, members of the association to be given the preference. After that date the price will be increased to twenty cents a square foot.

15,000 at Louisville Midsummer Show

LOUISVILLE, KY., July 11—Under the auspices of the Louisville Automobile Club this city's first annual midsummer automobile show was held last Thursday at Fontaine Ferry Park. Twenty exhibitors were represented in the display, which included gasoline pleasure cars, trucks and electrics. Many dealers handling some of the leading makes were unable to enter the exhibition because of their inability to secure models from their factories at this time, it was announced.

Optimism was in evidence everywhere among the dealers, and indications point to a splendid season next year. According to the majority of the dealers, business is much better than it was at this time in 1913, the principal complaint of the agents being that they cannot secure a sufficient number of cars from manufacturers. Local distributors are doing the bulk of their business out in the State, where the farmers and people living in small towns are purchasing cars in greater numbers than ever before. There seems to be the greatest demand for the machine selling in the neighorhobd of $1,000, and the small cars listed under $700 also have made great strides.

The midsummer show was staged in connection with a membership campaign being conducted by the Louisville Automobile Club. Fontaine Ferry, where the exhibition was held, is an amusement park. The event was designated as Automobile Day and about 15,000 people were in attendance.

Cadillac Owner Wins Consistency Trophy

DENVER, COL., July 10—The sweepstakes trophy for the best general average of consistent driving in the first annual All-Colorado Auto Derby, July 3, 4 and 5, was won by Harry W. Swigert, driving a Cadillac. Point cups for the five separate legs of the 280-mile run from Denver to Colorado Springs, Canon City, Pueblo and return were won respectively by Carl Ph. Schwalb in a Cadillac; Swigert, winner of grand prize; A. C. Lee in an Abbott-Detroit, E. H. Bull in a Franklin and Theodore Marx in a Locomobile.

The winning time for the entire course of 280 miles was 14 hours, 6 minutes and 15 seconds, which was within 9 minutes of the time secretly fixed by the timing committee as the most reasonable for covering the official route, namely, 14 hours and 15 minutes.

Tests of New Fuel Continue

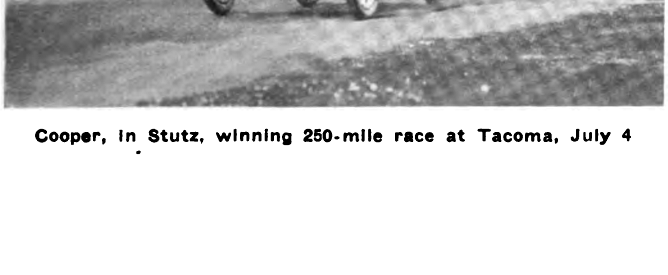
INDIANAPOLIS, IND., July 13—Experiments with the substitute for gasoline invented by John Andrews, of McKeesport, Pa., are still under way at the Indianapolis Motor Speedway and continue to attract wide attention. The experiments are being closely watched by Carl G. Fisher, president of the speedway company, and by chemists from other cities. It is understood steps are to be taken soon to place the substitute on the market.

The new fuel is distilled from water and chemicals. Andrews asserts it can be marketed at 5 or 6 cents a gallon. It can be made of any quality from 60 proof to 100 proof. The process of manufacture is rapid.

Several cars have been used in the experiments. A six-cylinder Cole using the substitute made 13.5 miles to the gallon, the substitute having a specific gravity of 60. Previously the same car made 12.9 miles to the gallon on 64-proof gasoline.

A National six-cylinder car made 16.5 miles to the gallon on 64-proof gasoline and later made 17.75 miles to the gallon on the substitute having a specific gravity of 60. Another National six-cylinder touring car, fully equipped, attained a speed of 56 miles an hour on 64-proof gasoline, then reached a speed of 60 miles an hour on 60-proof substitute.

A Marmon car made a continuous run of 116 miles on 9½ gallons of the substitute, an average of 12.2 miles to the gallon.



Cooper, in Stutz, winning 250-mile race at Tacoma, July 4

Rules Difficulties May Kill Wisconsin Tour

MILWAUKEE, WIS., July 13—There will be no revival of the Wisconsin State Automobile Assn. reliability tour for the Milwaukee Sentinel $1,000 trophy in 1914, and it looks as if the Badger motoring classic is dead for all time. Officers of the association claim that the A. A. A. will not grant a sanction for a grade 1 tour, nor permit the association to take its own steps to provide a stock car classification and registry. Therefore, for the second time, the 1,000-mile run is abandoned and unless the association makes good in 1915, there is scant hope that there will ever be another dealer's touring contest in Wisconsin, at least not under the W. S. A. A.'s auspices.

The tour was instituted in the summer of 1910 and proved a success. The trophy, which cost $1,000, was won by a Buick. In 1911 the Imperial was returned winner. Both tours were under the stringent grade 1 code of the A. A. A. In 1912 the promoter was not able to muster sufficient cars under this set of rules, so grade 3 regulations were invoked and all but three or four out of twenty-two cars came through with perfect scores and the Sentinel cup was not awarded, certificates and medals being distributed. In 1913 the W. S. A. A. ran up against the snag which put several other prospective contests in the United States out of business. The A. A. A. had no stock cars registered as required by grade 1 rules and could not grant the Badger promoters a sanction. The same situation confronts the Badgers this year.

Monihan Resigns from Cole Company

INDIANAPOLIS, IND., July 13—John Guy Monihan has severed his connection with the Cole Motor Car Co., this city, resigning the position of associate director of sales and advertising. Mr. Monihan states he will probably re-enter the automobile business this fall, but meanwhile will make an extensive automobile tour with his family.

Rudge-Whitworth Offers Prizes for Elgin

NEW YORK CITY, July 13—The Rudge-Whitworth Co., Ltd., Coventry, England, manufacturer of the Rudge-Whitworth detachable wire wheels, whose license is held in this country by the Standard Roller Bearing Co., Philadelphia, Pa., will offer the following prizes to the cars coming in first and second in the Elgin Road Race, held by the Chicago Automobile Club this year, August 21, provided the cars are equipped with Rudge-Whitworth detachable wire wheels: First, $200; second, $100.

Will Tour to Yellowstone Trail Meeting

MINNEAPOLIS, MINN., July 11—The automobile tourist caravan for the annual meeting of the Yellowstone Trail Association meeting, August 5 and 6, at Hunter Hot Springs, Mont., will leave Minneapolis July 27. Stops will be as follows: July 27, Montevideo; 28, Aberdeen, S. D.; 29, McIntosh, S. D.; 30, Marmarth, N. D.; 31, Miles City, Mont.; August 1, Billings, Mont.; August 3, Hunter. The association will lay plans at the convention for the government to open Yellowstone Park to motor cars and to extend the trail to Seattle. Government stone crushers from the Panama Canal Zone are expected to be loaned for the trail work.

Cyclecar National Association Elects New Directors

DETROIT, MICH., July 13—Active organization work has been inaugurated by the Cyclecar Manufacturers' National Assn. At a meeting in this city July 5 F. Ed. Spooner was elected secretary, with offices at 903 Free Press Building. Two vacancies in the board of directors were filled by the election of W. I. Twombly, of the Twombly Motor Corp., New York City, and W. Lumb, of the Flagler Cyclecar Co., Cheboygan, Mich. The makers at the meeting decided to encourage the promotion of contests of every character, including track races, hill climbs, etc.

Factory Miscellany

DENBY Truck Opens Factory—The Denby Motor Truck Co. has started business in Detroit with offices at 2036 Dime Bank Building, and a factory at Dubois and Franklin street. The factory has 20,000 square feet of floor space, which is to be doubled later, option having been taken on the additional room. Contracts have been placed for material for 500 trucks for the first year, with an increase to 1,000 trucks as the business develops. Particulars regarding the truck that will be manufactured are withheld at present but it will run from 1,500 pounds to 1-ton in capacity, according to reports. Garvin Denby is president and general manager of the company; J. Walter Drake is vice-president of the new company; Arthur Webster is secretary, and Edwin Denby, treasurer; L. C. Freeman is engineer, while R. P. Spencer is sales manager, with R. F. Moore advertising manager.

Southern Tire Co. Builds—The Southern Tire & Rubber Co., Augusta, Ga., will erect a plant to manufacture tires, etc. It will be 50 by 200 feet, with brick construction, and will cost approximately $9,000.

Will Furnish Atlas Spare Parts—The Auto Parts & Repair Co., Springfield, Mass., has purchased the repair end of the Atlas Motor Car Co. and can furnish all parts for 2-cycle engines at all times.

Simplex Co. Manufacturing Rims—The Simplex Demountable Rim Co., Milwaukee, has been organized to manufacture automobile rims and tire appliances. The capital stock is $150,000 and the promoters are M. Rosenheimer, W. J. Sarres and M. H. Rosenheimer. It has been engaged in manufacturing on a small scale for several months, but intends to lease larger factory quarters at once.

Richard Co. Will Build—The Richard Automobile Mfg. Co., Cleveland, expects shortly to begin the erection of a plant on Finney avenue and the Belt Line Railroad for the manufacture of touring cars. There will be provided 25,000 square feet of floor space. As the parts will be made by other plants, the work in the plant will be confined mostly to assembling, so that little machinery will be required, although a few small machine tools may be purchased.

Lord Baltimore's New Building—The Lord Baltimore Truck Co., Baltimore, Md., will move into its new building on July 20. This plant, situated on Bank and Fifth streets, Highlandtown, Baltimore, is 50 by 140 feet, two stories high with a 6-ton elevator. This building will be devoted to the manufacturing of Lord Baltimore internal gear-driven 1 and 2-ton trucks. In the new quarters there will be a paint shop and the cars will be finished complete by the company. The company has just received an order from the War Department for a 1½-ton truck.

Alter Co. in New Plant—The Alter Motor Car Co., formerly at 1146 Grand River avenue, Chicago, has moved into its new plant in Plymouth, Mich., a two-story plant, 50 by 200 feet. The concern, which is a new one, recently shipped its first ten cars and has several hundred cars booked to be delivered within the next few months. "We will be pretty busy from now on," said H. P. Choate, of the company, "catching up with our back orders. We have been delayed, especially because it took much longer to get the plant fixed up than had been anticipated."

Studebaker Acquires New Building—The Studebaker Corp., Detroit, Mich., has recently acquired the building at Hastings street and the Boulevard, Detroit, which will be used as a service department. This gives the Studebaker over 100,000 square feet of additional floor space, and means the employment of about 100 more men. When the 1,200 feet of new loading docks on Clark and Jefferson avenues, Detroit, will have been erected the Studebaker Corp. will have facilities to handle 800 freight cars per day.

Automobile Plant for Calumet—A letter has been received by Secretary George L. Price, of the Commercial Club of Calumet, Mich., from a new motor car manufacturing company, recently organized, but whose name will not be made public at present, and which desires to locate its plant in the Michigan copper district. The automobile company, in its correspondence, stated that it will have a yearly output of 1,500 cars and give employment to a large number of men.

Will Manufacture Garage Tools—The International Electric Tool Co. has been organized in Milwaukee, Wis., by a number of well known men in the electrical and engineering field to engage in the manufacture of a line of electrical tools for garages, machine shops, foundries, etc. The officers are; President, William R. Sorgel; vice-president and secretary, William H. Gaulke; treasurer, E. K. Rundle. Factory space has been leased and equipment is now being installed.

Simmons Co.'s Three New Buildings—The Simmons Mfg. Co., Kenosha, Wis., a large producer of spring sets for motor car cushions and upholstery, and the largest manufacturer of metal beds and parts in the world, has broken ground for three additions to cost $100,000 and be completed by August 15. The buildings will consist of a machine shop, pattern shop and drafting room, 60 by 260 feet; a gray iron, brass and bronze foundry and blacksmith shop, 60 by 200 feet; and a pattern storage house, 40 by 125.

The Automobile Calendar

July 18-19	Seattle, Wash., Track Meet, Meadows Amusement Co.

The Week in  the Industry

Motor Men in New Roles

DODGE BROS. Announce District Agents—Dodge Bros., Detroit, have made the following appointments as district representatives: C. W. Matheson, in New York, with jurisdiction over the eastern half of that state, the northern half of New Jersey, the eastern half of Pennsylvania and the state of Connecticut. Mr. Matheson is well known in the trade, having been the organizer and president of the Matheson Motor Car Co., Wilkes-Barre, Pa., and later of the Matheson Automobile Co., New York. More recently he was first, western manager for the Palmer-Singer Co., and then became their general sales and advertising manager. F. L. Jones, formerly with S. F. Bowser & Co., the tank makers, and with Armour & Co., Chicago, will look after the Dodge Bros. interests in Philadelphia. A. C. Templeton, formerly in charge of the Kisselkar Sales Co. for northern Wisconsin and Michigan and at one time Detroit representative for these cars, and later with the Winton Motor Car Co., will have charge of Minneapolis and the surrounding territory. C. H. Hurst, formerly in Canada and more recently in Chicago with the White, will look after the business in Omaha, Neb., and surrounding territory.

Jones Lippard-Stewart Representative—C. R. Jones has been appointed district representative of the Lippard-Stewart Motor Car Co., Buffalo, N. Y., with headquarters in Dallas, Tex.

Smith Chandler Sales Manager—E. V. and Lionel Armstrong have taken charge of the new home of the Chandler Motor Car Co. in Los Angeles. D. P. Smith has been named sales manager.

Evans Goodyear Service Manager.—D. E. Evans, formerly sales manger of the General Motor Truck Co., St. Louis, Mo., is now service manager of the Goodyear Tire & Rubber Co., Detroit.

Hole Manager—The Wilcox Motor Car Co., St. Louis, Mo., has appointed a new manager for the St. Louis branch. He is Frederick E. Hole and succeeds J. P. Gertsen, who resigned because of ill-health.

Horton with Dodge Bros.—E. J. Horton, recently Eastern sales manager of the Empire Automobile Co., Indianapolis, Ind., and who also was with the R-C-H Corp., is now a member of the staff of Dodge Bros., Detroit.

Jacks Retail Sales Manager—O. A. Jacks has been appointed retail sales manager of the La Crosse Auto Co., 921 Hennepin avenue, Minneapolis, Minn. The company handles the Marathon, Imperial and Herreshoff cars.

Greene Succeeds Weldon—F. A. Greene succeeds Frank Weldon as manager of the Cole Motor Co., Des Moines, Ia. Mr. Weldon continues his connection with the company and probably will accept another agency in the state.

O'Brien Goes to Newark—Manager Sills of the Chevrolet Co., of New England, has transferred F. O'Brien, the head salesman at the Boston branch, to Newark, N. J., where he will be manager of the company's branch there.

Lersch Herreshoff Sales Manager—V. D. Lersch, manager for the Goodyear Rubber Tire Co., Albany, has resigned that position to become sales manager for the Herreshoff Motor Sales Co., the general sales agents for the Herreshoff Light Car Co.

Join Locomobile Branch—J. W. Burke, formerly with the sales staff of the New England Fiat branch, and W. S. Porter, of New York, are two recent additions to the sales department of the Boston branch of the Locomobile Co., the latter being sales manager.

Butler Makes Change—A. I. Butler, formerly manager of the Goodyear Tire & Rubber Co., Brooklyn, N. Y., is associated with The Batavia Rubber Co., New York City, in the capacity of special representative. Mr. Butler will look after northern New York territory.

Marcotte in Detroit—Roy E. Marcotte, for the past two years manager of the advertising department of the Canadian branch of the Studebaker Corp., Detroit, Mich., is now with the Detroit Studebaker and will continue taking care of the Canadian publicity from there.

McKenny Makes Change—N. E. McKenny, formerly with the American Steel & Wire Co., the American Plow Co., Madison, Wis., and the Zender, Paeschke Frey Co., Milwaukee, Wis., is now with the Federal Motor Truck Co., Detroit, being in charge of the promotion department.

Mooney Hupp Sales Manager—F. J. Mooney, advertising expert of the Hupp Motor Car Co., Detroit, Mich., who had temporary charge of the spring selling campaign, has been appointed sales manager of that company, in addition to being in charge of the advertising department.

Voorheis Oakland Sales Manager—C. B. Voorheis, until recently sales manager of the King Plow Company, Peoria, Ill., has been appointed sales manager of the Oakland Motor Car Co., Pontiac, Mich. He will be closely associated with Vice-President and General Sales Manager F. W. Warner.

Williams Heads Haynes Agency—The Haynes Auto Co., Kokomo, Ind., has established an office in this city at Fourth avenue and York street. Dave Williams, formerly connected with the advertising department of the American concern at Indianapolis, is the representative of the factory in charge here.

Joe Dawson Improving—Joe Dawson, who was injured in the 500-mile race at Indianapolis, Ind., May 30, while driving a Marmon car, is much improved. He is still in the hospital and it may be several weeks before he is able to be out. It is announced at the hospital, however, that his complete recovery is assured.

Macey Resigns—R. Ward Macey, Jr., recently severed his connection with the Premier Motor Mfg. Co., Indianapolis, Ind., but retains his interest in the company as a stockholder. Before becoming sales manager of Premier, Mr. Macey was in the sales department of Franklin, and before with Henry Ford.

Spear with Scripps-Booth—R. H. Spear, formerly a specialist in factory organization, management and executive administration and editor of the "Commercial World Encyclopedia of Accounting," has been appointed general manager of the Scripps-Booth Co., Detroit, makers of the Scripps-Booth cyclecars.

Campbell's New Job—C. I. Campbell, secretary of the Boston Automobile Dealers Assn., has been made manager of the Rockingham Fair, which will take place at Salem, N. H., during the first week of September on the big grounds formerly devoted to horse racing, and later where automobile contests were held.

New Resigns—Dr. Norman R. New, sales manager of the Milwaukee branch of the Mitchell Automobile Co., Chicago, resigned July 1 to resume his association with the home office and headquarters in Chicago after a 2-year stay in Milwaukee. H. W. Bonnell, local manager, assumes the position of sales manager in addition to his other duties.

Brandt Joins Hudson Forces—E. H. Brandt has resigned from the Detroit-Cadillac Co., New York City, to become the general eastern representative of the Hudson Motor Car Co., Detroit. He will make his headquarters in New York City and will have charge of the Hudson company's eastern business in the territory including the Eastern States and eastern Canada.

French National Advertising Manager—L. S. French has become advertising manager of the National Motor Vehicle Co., Indianapolis, succeeding P. P. Willis, who resigned to accept a position with the advertising agency of Thomas Carroll Tripp, Cleveland, O. Mr. French until recently was with the Henderson Motor Car Co., and prior to that was with the Cole Motor Car Co.

Sudrow King Sales Manager—F. G. W. Sudrow has been appointed by the King Motor Car Co., Detroit, Mich., as southern district sales manager. Mr. Sudrow was for 8 years secretary and treasurer of the National Battery Co., of Buffalo; for 2 years was connected with the Stoddard-Dayton Motor Car Co., of Dayton, O., and has also been sales manager of the Apple Electric Co. and the Marion Motor Car Co. He has a wide acquaintance of friends throughout the southern section, and will assume his duties July 1.

Smith Heads Regal Agency—R. C. Smith, formerly with the Minnesota Motor Sales Co., and A. P. Heaney, lately with the La Crosse Auto Co., both of Minneapolis, Minn., are now respectively president and general sales manager of the Regal Motor Car Company, of Minneapolis, which has been incorporated with a capital stock of $25,000, and will act as distributors for the Regal cars in Minnesota, North Dakota, the Northern half of South Dakota and Western Wisconsin. The company is located at 1400 Hennepin avenue.

Recent Incorporations in the Automobile Field

AUTOMOBILES AND PARTS

BUFFALO, N. Y.—Hudson-Oliver Motor Co.; capital, $15,000; automobiles. Incorporators: E. G. Oliver, George B. Wesley, Charles W. Pooley.

CHICAGO, ILL.—Halleman Motor Livery Co.; capital, $1,000; construct, maintain, operate and deal in automobiles. Incorporators: G. W. Halleman, F. H. Janowisk, Harry De Coudres, J. Dulsen.

CLEVELAND, O.—Atlas Tire and Rubber Co.; capital, $5,000; to deal in automobiles, tires, etc. Incorporators: J. M. Bernstein, E. E. Gross, N. J. Baker, F. Allen, J. M. Ulmer.

CLEVELAND, O.—Trenton Motor Sales Co.; capital, $5,000; to deal in automobiles. Incorporators: W. K. Stanley, J. R. Jewitt, P. C. Steller, S. Horwitz, I. A. Skinner.

COLUMBUS, O.—Justus & Parker Co.; capital, $15,000; to deal in automobile supplies and accessories. Incorporators: E. E. Parker, C. E. Justus, H. M. Parker, Bernard Smith, J. A. Justus.

COLUMBUS, O.—Tesseyman Auto Co.; capital, $20,000; to deal in automobiles. Incorporators: J. E. Tesseyman, I. A. Tesseyman, F. N. Boyd, J. F. Galloway, M. Heinrich.

DETROIT, MICH.—Steere Engineering Co.; capital, $50,000; to manufacture engines, etc. Incorporators: W. S. Blauvelt, Currier Lang, A. H. Green, F. W. Steere.

DETROIT, MICH.—Simplex Engine Co.; capital, $40,000; to manufacture engines. Incorporators: H. Fraser, W. G. Taylor, F. Smallridge.

DETROIT, MICH.—Princess M. C. Co.; capital, $100,000; automobiles. Incorporators: Ola C., I. N. White, K. F. Klein.

HAMILTON, O.—Miami M. C. Co.; capital, $10,000; to deal in automobiles and supplies.

MINNEAPOLIS, MINN.—Regal Motor Co.; capital, $25,000; to deal in automobiles. Incorporators: R. C. and I. E. Smith, J. Costella.

MOLINE, ILL.—Kellogg Turbine Muffler Co.; capital, $15,000; general manufacturing, including automobile parts and accessories. Incorporators: E. M. Kellogg, E. M. Kellogg, Jr., E. C. Brain.

MONTREAL, CAN.—Stockwell Motors, Ltd.; capital, $100,000; to manufacture automobile trucks. Incorporators: F. B. Stockwell, E. E. Leger, H. E. Walker.

NEW YORK CITY—James C. Stopps; capital, $15,000; automobiles. Incorporators: James C. Stopps, Jos. M. Palmer, Louis C. Goetting.

NEW YORK CITY—Motor Credit Co.; capital, $1,000; to deal in automobiles. Incorporators: Arthur Enock, Adolph Morris, David Grinberg.

OSWEGO, N. Y.—Ontario Motor Car Co.; capital, $5,000; automobiles. Incorporators: Arthur P. Wolever, Frank C. Wolever, Chas. A. Peterson.

OWEGO, N. Y.—B. Z. T. Car Co.; capital, $25,000; to deal in automobiles. Incorporators: F. M. Baker, F. D. Baker, C. K. Bell, all of Owego.

PHILADELPHIA, PA.—Crown Tire & Supply Co.; capital, $100,000; to manufacture, sell and deal in automobiles and accessories. Incorporators: F. W. Thompson, B. S. Edwards, J. M. Frere.

PHILMONT, N. Y.—High Rock Motor Co.; capital, $5,000; to manufacture motors. Incorporators: F. B. Harder, P. M. Harder, L. F. Harder, all of Philmont, N. Y.

PUNXSUTAWNEY, PA.—International Motor Co.; capital, $15,000; to manufacture rotary motors. Incorporators: C. M. Long, Jacob E. Wolf, William Burley, J. P. North, A. B. North, Odessa Whiting, F. J. Smith, I. N. Graffius.

ROCHESTER, N. Y.—Pritchard-Lyon Motors Corp.; capital, $25,000; to manufacture motors. Incorporators: P. H. Pritchard, Aast avenue, Brighton, N. Y.; A. R. Pritchard, C. B. Lyon.

ST. LOUIS, MO.—Champion M. C. Co. of Missouri; capital, $50,000; to deal in automobiles. Incorporators: A. R. Walton, O. A. Peters, E. D. McMahon.

TORONTO, ONT.—Dominion Motor Car Co.; capital, $40,000; automobiles.

WATERLOO, IA.—Waterloo Overland Co.; capital, $10,000; automobiles and accessories. Incorporators: John Hanson, J. H. Hadley.

WATERVILLE, N. Y.—Hale Auto Corporation; capital, $500; automobiles. Incorporators: J. Chas. Hale, Augusta M. Hale, Chas. R. Hale.

GARAGES AND ACCESSORIES

BROOKLYN, N. Y.—Bedford Taxi Cab Co.; capital, $5,000; general taxicab business. Incorporators: Isaac Cohen, 128 Hamboldt street, Brooklyn; Abr. Gurewitz, B. H. Fraum.

BRONX, NEW YORK CITY—Grand Concourse Garage Co.; capital, $5,000. Incorporators: John M. Ireland, Mary A. Ireland, Caroline Haffen.

BRONX, NEW YORK CITY—Puncture Seal Co.; capital, $5,000; to manufacture compounds for mending inner tubes, tire accessories, etc. Incorporators: Henry D. Bahn, Frank S. Murray, Frank Eber.

CHICAGO, ILL.—Davis Automobile Accessories Co.; capital, $25,000; manufacturing automobile accessories. Incorporators: E. M. Oehlert, A. S. Kedzie, Harry Garrett.

CLEVELAND, O.—Atlas Tire and Rubber Co.; capital, $5,000; to deal in automobile tires. Incorporators: J. M. Bernstein and others.

CLEVELAND, O.—Harris-Henderson Tire Co.; capital, $5,000; to deal in tires and accessories. Incorporators: J. A. Harris, F. A. Henderson, J. C. Barkley, R. L. McVean, J. P. Dempsey.

GALION, O.—Galion, Mt. Gilead and Cardington Motor Transit Co.; capital, $20,000; to operate a motor bus line. Incorporators: G. C. Hornatin, F. B. McMillin, C. B. Marsh, D. J. Donavin, C. J. Cugler, E. H. Conaway, M. L. Phillips.

HAMILTON, ONT.—National Rubber Co., Ltd.; to manufacture automobile tires. Incorporators: Geo. Wenig, D. B. Wood, R. W. Long, Chas. L. Boyd, F. E. Walker.

HEMPSTEAD, N. Y.—Comfort Shock Absorber Co.; capital, $500; to manufacture shock absorbers for automobiles. Incorporators: Geo. G. Bouthinon, Ida Bowdren, Geo. P. Bowdren.

INDIANAPOLIS, IND.—Gates Mfg. Co.; capital, $20,000; to manufacture motor car tops and seat covers. Incorporators: F. E. Gates, R. A. Gates, F. O. Lane.

MINNEAPOLIS, MINN.—Lyndals Garage Co.; capital, $25,000; to deal in automobiles. Incorporators: C. E. Bullock, H. M. Lewis, E. O. Miller.

MT. GILEAD, O.—Galion, St. Gilead and Cardington Motor Transit Co.; capital, $20,000; general bus line.

NEW YORK CITY—Hollywood Garage Corporation; capital, $30,000. Incorporators: John J. Pheelan, Gerald A. Grant, Max Frieder.

NEW YORK CITY—Independent Auto Renting & Garage Co.; capital, $500. Incorporators: Thos. Callahan, Chas. M. Siegel, Chas. Pechner.

NEW YORK CITY—New York Steam Auto Tire Works; capital, $10,000. Incorporators: John J. Foley, Minnie Beck, J. A. Callanan.

NEW YORK CITY—Public Service Auto Co.; capital, $1,000. Incorporators: Frank J. Bryant, Henry Wilber, Henry F. Carden.

NEW YORK CITY—Wall Street Taxi Cab Co.; capital, $1,000. Incorporators: Bessie O'Hare, John J. O'Hare, Danl. O'Donnell.

NEW YORK CITY—Western Tire Co. of America; capital, $5,000; general tire business. Incorporators: L. Walter Lisberger, Joel Jacobs, Frank H. Cross.

NEW YORK CITY—Seventh Street Garage; capital, $10,000; garage business. Incorporators: S. Frankfater, J. Klinger.

NEW YORK CITY—Imperial Auto Touring and Taxicab Co.; capital, $1,000; general taxicab business. Incorporators: A. S. Gussow, 621 East 3d street, New York City; A. Miller.

NEW YORK CITY—Progress Auto Renting Co.; capital, $1,000; to rent automobiles. Incorporators: Morris Klein, 101 W. 114th street, N. Y. City; Samuel Klein, A. P. Blum.

PITTSBURGH, PA.—Auto Sprinkler Equipment Co.; capital, $25,000; to manufacture automobile sprinklers. Incorporators: H. A. Logue, H. C. Fry, Jr., J. E. Stone.

QUEENS, N. Y.—Astoria Taxicab Corp.; capital, $3,000; taxicab business. Incorporators: G. L. Doyle, W. F. Wund, A. V. Kenealy.

ROCK ISLAND, ILL.—Sandbo Starter Co.; capital, $10,000; to manufacture and deal in engine starters. Incorporators: H. W. Danimann, A. G. Arp, A. I. Sandbo.

SAN FRANCISCO, CAL.—Swan Carburetor Co.; capital, $200,000; to manufacture carburetors. Incorporators: H. S. Hutchings, E. M. Boynton, B. W. Boynton.

SAVANNAH, GA.—Harris Tire Co.; capital, $40,000; to manufacture automobile tires. Incorporators: S. N. Harris, H. M. Garmany, C. S. Richardson, L. B. Rith, M. B. Brabham, J. E. Mosher, E. De Loach, J. L. Sellers.

TOLEDO, O.—Rupp-Skeldon Motor Co.; capital, $50,000; to manufacture and deal in all kinds of motors. Incorporators: Robert G. Young, James Nye, James Greenwald, Bess Young and B. W. Johnson.

TULSA, OKLA.—Hi-Grade Gasoline Co.; capital, $1,000; to deal in gasoline. Incorporators: B. Revel, D. C. Rose, R. S. Fellows.

WARREN, O.—Auto Test Co.; capital, $20,000; to deal in automobile supplies. Incorporators: F. L. Spellman, H. E. Vaughan, H. G. Paden, F. W. Andrews and C. S. Vaughan.

WHITE PLAINS, N. Y.—Ashley Wire Wheel & Rim Co.; capital, $50,000; manufacture wire wheels and rims for autos. Incorporators: R. W. Ashley, F. W. Kolb and Henry L. Stuart.

WILMINGTON, DEL.—International Motor Wheel Co.; capital, $1,000,000; to manufacture automobile wheels. Incorporators: H. E. Tatter, W. J. Maloney, O. J. Reichard.

CHANGES OF NAME AND CAPITAL

CLEVELAND, O.—Alco Motor Co.; name changed to Main Motor Co.

DETROIT, MICH.—Canfield Garage Co.; capital increased from $5,000 to $12,000.

DETROIT, MICH.—Fischer Closed Body Co.; capital increased from $125,000 to $500,000.

INDIANAPOLIS, IND.—Service Motor Car Co.; change of name to Service Motor Truck Co.

OKLAHOMA CITY, OKLA.—Globe Petroleum Co.; capital increased from $8,000 to $24,000.

PORT WASHINGTON, WIS.—Turner Mfg. Co.; capital increased from $100,000 to $150,000.

Accessories for the Automobilist

DINSHAH Motor Tester—An electrical device showing where the motor is at fault, whether this trouble is electrical or mechanical, has been brought out by the Dinshah Sales Corp., 735 Seventh avenue, New York City. While it is attached to the high-tension circuit it is so delicately attuned that it will show all the ordinary mechanical troubles, such as lack of compression, faulty armature bearings, etc.

The tester, Fig. 1, consists of a set of spark gaps, one for each cylinder, and a set of vacuum tubes that give varying colors, depending on the condition of the electrical circuit and the motor. This outfit is housed in a box provided with a convenient visor that keeps out the light and aids in watching the operation of the instrument.

In a four-cylinder motor, for example, there are heavily insulated wires provided with clip terminals so that they may be quickly attached to the spark plugs or magneto terminals. These wires run to individual terminals in the bottom of the tester box. On one side of these terminals are the spark gaps and on the other side are the vacuum tubes. The return connections are grounded through a single wire that is also provided with a clip terminal so that it can be attached to any convenient metal part.

Note the Sparks

In testing a motor the first thing to do is to determine whether all cylinders are receiving sparks that are both hot and properly timed. This is accomplished by disconnecting the spark plug terminals and attaching the four leads of the motor tester to the magneto terminals. Then the motor is cranked over by hand, and if the sparks occur in the regular order and if the tubes show flames of a uniform color, then the ignition and timing is all right. It must not be overlooked to connect the leads from the tester according to the firing order of the motor. If this is done the sparks will occur in 1-2-3-4 order in the instrument. The spark gaps are set at such a distance that it takes the same voltage for the current to jump the gap as is required when the spark crosses the plug gap under compression. In other words, the resistance offered by the atmospheric air gap is equal to the resistance offered by the smaller gap under full compression pressure.

Where it is inconvenient to crank the motor by hand or by a starter, it may be run on two cylinders while the other two are being tested.

Having determined that the sparks are of good quality and that the firing order is correct, all the high-tension wires are connected up again and the four-tester leads are fastened to the spark plug terminals.

It will be noted that on the inside of the tester cover there is a full set of instructions so that anyone can determine, in an instant, just where the trouble is. These directions are divided into two parts, one set referring to the testing of the electrical generating system, as it is called, and the other to the spark plugs, carbureting system and compression.

Testing Directions

For testing the electrical generating system, disconnect the spark plug wires and connect them to the four leads running from the tester, and ground the fifth. Turn the crank, or operate the self-starter and look into the instrument.

1—A regular succession of white sparks at the gaps, accompanied by colored flashes in the four tubes, indicate a perfect electrical generating system.

2—If the sparks miss irregularly the trouble is due to a faulty distributor.

3—If the sparks skip back and forth regularly in two tubes, a loose armature bearing is indicated.

4—Sparks missing in two tubes show that the contact breaker is faulty.

5—All tubes flashing without sparks or with irregular sparks means weak batteries, magnets or loose connections.

6—Darkness in one tube—no electricity in that cable.

7—Darkness in all tubes—dead electrical generating system.

8—Sparks in any tube without a flash show that the engine tester is out of order and should be returned to the makers.

Having put the electrical generating system in perfect order connect the high-tension wires to the spark plugs and hook on the four clips. Then run the motor. Under these conditions no sparks will be seen, the condition of the motor being indicated solely by the colors in the tubes.

9—If all the tubes are flashing the same color the spark plugs are in perfect condition.

10—If the motor continues to operate badly the trouble is due to carburetion.

11—If a tube flashes and darkens irregularly there is a leakage of electricity or the plug point is dirty or too close.

12—A dark tube indicates that that plug is short-circuited.

13—A blinking tube shows that there is a loose connection.

14—A tube flashing very dull in comparison with the others indicates that there is a loss of compression.

15—If a tube sparks when the motor turns slowly it shows that the plug points are too far apart.

The motor tester is made with four, six and eight leads for motors of corresponding numbers of cylinders and it is planned to manufacture one with two leads for the cyclecar and motorcycle trade.

Gahm Auto Starter—A simple starter which is operated by a lever on the dash is manufactured by the Gahm Mfg. Co., Streator, Ill.

It consists merely of a crank that is attached to a cable running over a pulley to the dash. When the handle on the dash is pulled the motor is cranked.

To facilitate starting a primer that holds more than a quart of gasoline and connects direct with the intake manifold by a small pipe is used. Flow of gasoline to the manifold is controlled from the dash.

O-Lax Carbon Remover—A liquid oxygen carbon remover called O-Lax is being marketed by the Wilkes & Grant Co. of Louisville.

To remove the carbon the motor is run until hot, then take out the spark plugs of two cylinders, turn engine over until the valves are closed and see that the valves are seated. Put in from 2 to 3 ounces of the liquid in the cylinders, replacing the spark plugs immediately after, as the liquid changes into an oxygen gas when it touches the hot cylinders. After fixing the two closed cylinders and replacing the spark plugs, let same stand from 10 to 15 minutes, then the motor is started and the carbon blown out through exhaust by speeding up the motor. Then treat the remaining cylinders same as above until car is cleaned.

O-Lax is put up in quart sizes selling at $2.50, 5 gallon selling at $4.50 and 1 gallon selling at $8. A guarantee to refund money if O-Lax does not remove the carbon from the engine is given each purchaser.

The AUTOMOBILE

Mercedes Grand Prix Racers —Their Warp and Woof

Four Steel Cylinders Used with Waterjackets Welded On— Four Spark Plugs Per Cylinder, Four Valves Per Cylinder —Mechanism Horizontal Throughout—Streamline Body

By W. F. Bradley

PARIS, July 11—A set of cars which can win first, second and third places in the greatest European road race of the year, and against the finest racing cars Europe can produce, must possess many features of interest to the average motorist, the engineer and the racing fan.

The winning Mercedes cars in the French Grand Prix were jealously guarded before the race and were even kept under close watch immediately after the contest. It has now been possible, however, to obtain some particulars of their structural features.

As is well known, this year's French rules fixed a piston displacement limit of 274.6 cubic inches and imposed a maximum weight of 2,425 pounds. Mercedes complied with the rules by building a set of four-cylinder cars of 93 by 165 millimeters, 3.6 by 6.49 inches, bore and stroke. This is a stroke-bore ratio rather above the average. With the exception of Peugeot, which had 92 millimeters bore, the Mercedes had the smallest cylinder diameter. The great majority adopted 94 by 160 millimeters. Mercedes was the only firm taking advantage of the rule allowing five cars to be entered in the race. All others were content to compete with three cars.

While these racing machines are special productions designed and prepared for the particular set of roads around Lyons, much of the experience gained in the Mercedes aviation motor has been incorporated in their design. The chassis is distinctive by being of uniform width throughout and having a double kick-up, one over the front and the other over the rear axles. The rear springs are underslung, and the mechanism is absolutely horizontal throughout.

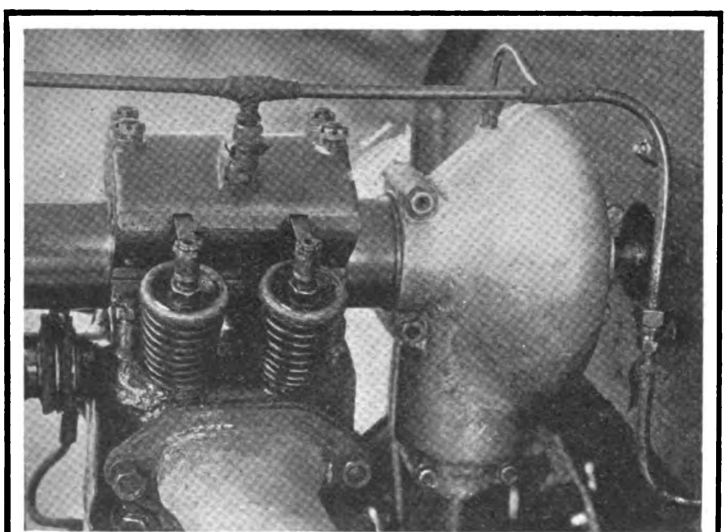

Fig. 1—Mercedes Motor—Each forged steel cylinder was fitted with two intake and two exhaust valves operated from an overhead camshaft with sixteen cams

The motors possess four separate steel cylinders machined out of the solid forging. Welded-on steel jackets are made use of; the combustion chamber is hemispheric and has four valves, two for the intake and two for the exhaust, placed in the head and inclined 30 degrees from the vertical.

Valve diameters are not known. It is estimated that they are 1.6 and 1.7 inches, but the secret is so well kept that this cannot be considered as more than an estimate.

A single overhead camshaft, with sixteen cams, operates the valves by means of rocker arms. The bronze camshaft housing is

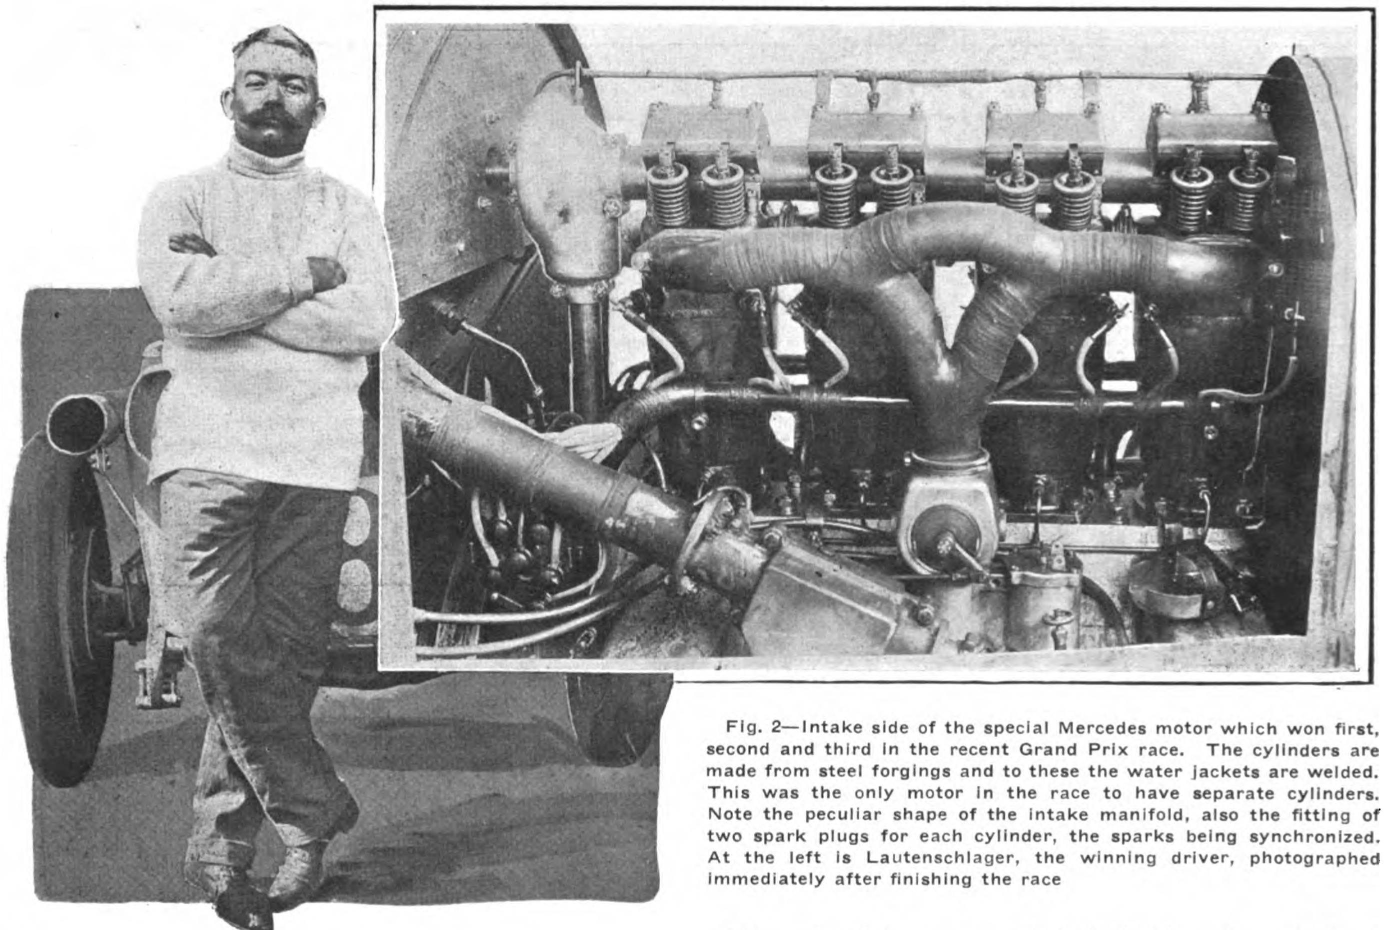

Fig. 2—Intake side of the special Mercedes motor which won first, second and third in the recent Grand Prix race. The cylinders are made from steel forgings and to these the water jackets are welded. This was the only motor in the race to have separate cylinders. Note the peculiar shape of the intake manifold, also the fitting of two spark plugs for each cylinder, the sparks being synchronized. At the left is Lautenschlager, the winning driver, photographed immediately after finishing the race

bolted to the head of the cylinders, and above each cylinder there is a detachable cover on the camshaft housing held down by four bolts and carrying the rockers. The ends of these latter thus project through the housing, and the springs are external. A vertical shaft at the rear of the motor and driven by a pair of bevel gears from the crankshaft, operates the camshaft, the upper pair of bevels being contained within an aluminum housing.

Very light cast-iron pistons are employed. The crankshaft is carried in five plain bearings and the camshaft in ball bearings.

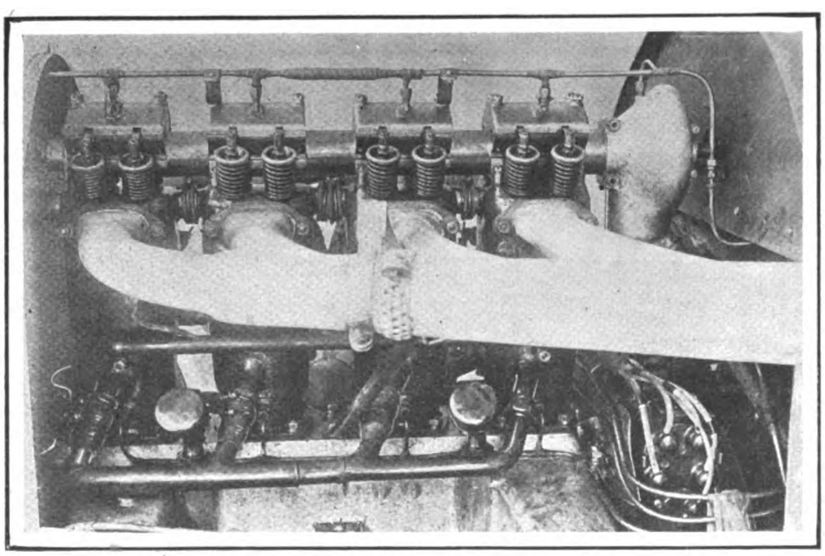

Fig. 3—Exhaust manifold of the Mercedes which is carried well out from the cylinder. Note the series water connections at the top of the cylinder jackets. Two magnetos were used, being mounted at opposite ends of the transverse shaft in front of the dash. Provision was made for four plugs in each cylinder to be fired in synchronism, but only three were used in the race

Compression is declared to be 8 kilos per cubic centimeter and the horsepower 110 to 115 at 3,000 revolutions. Several makers claim to get higher power than this, but their statements must be received with a certain amount of caution.

A transverse shaft at the rear of the motor drives two Bosch double magnetos. Provision has been made for four plugs, firing simultaneously, but in the race the cars only used three, one under each intake valve and one under an exhaust valve. The water pump is carried at the front of the motor, being on a vertical shaft driven from the front of the crankshaft. The radiator is a Mercedes honeycomb V type.

Uses Perforated Crankshaft

There are some distinctive features in the lubrication system. The crankshaft is perforated, and the oil pump, driven off the extension of the vertical shaft operating the camshaft delivers oil to the main bearings and through the internal oil ways to the connecting-rod ends. In addition there are external oil leads to the base of the cylinders on each side, to each rocker arm housing, to the upper pair of bevel pinions, and also through the hollow camshaft. While the pump takes oil from the base chamber it also draws on a reserve tank set across the frame on the floor boards just under the driver's legs. By this means a determined level of oil is always maintained in the base chamber.

On one side of the dash there is a second reserve oil tank with a foot operated plunger pump connected with it. By means of this pump the mechanic can send a supplementary supply of fresh oil to the main bearings, to the cylinder walls and to the overhead valve gear. The quantity of oil carried in the base chamber and in the main reserve tank under the men's legs is about 12 gallons. All cars went through the race without replenishing their oil supply.

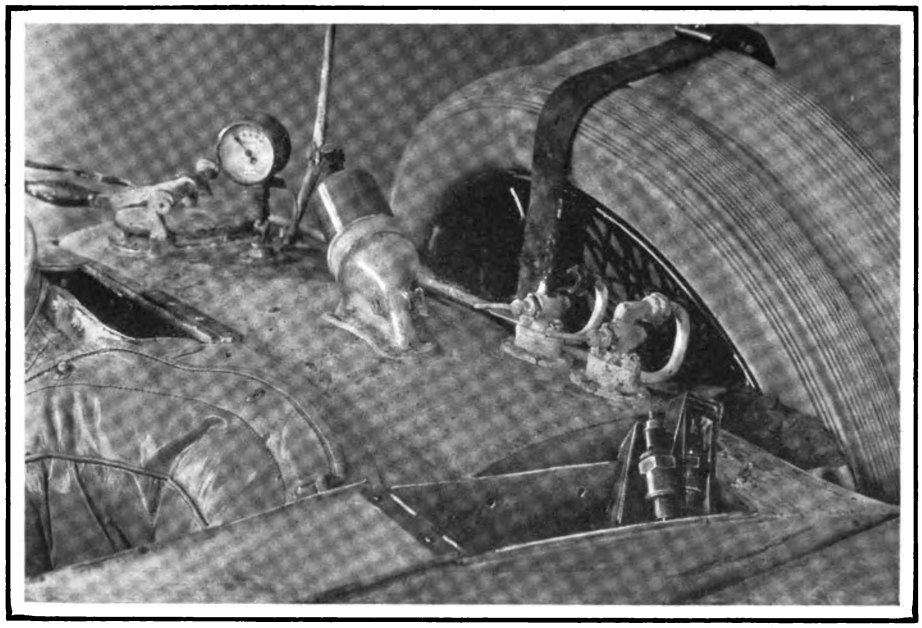

Fig. 4—Rear end of Mercedes racer showing gasoline tank mounted transversely together with various tool-carrying compartments around the tank. At the left side is a compartment for spare spark plugs and other articles. At the right is a compartment for the thermos bottle. In the center are two spaces for jack and jack lever

A separate lubricating system is provided for the water pump. Thick grease is used, but in order that the mechanic may supply this lubricant while the car is under way, the pipe from the lubricator is brought up to the dashboard and a big screw-down grease cap is provided. The supplementary oil tank also allows a delivery of oil to the forward universal joint, and on some of the cars feeds were provided to the four shock absorbers protected by leather gaiters.

Three-Point Radiator Support

The motor has rigid four-point attachment to the main frame members. The radiator on the other hand has three-point trunnion attachment to the frame. The gearbox is also a rigid four-point attachment to the frame, the connection between it and the motor being by means of double cone clutch. The flywheel is of unusually small size. A single Mercedes carbureter is made use of, the only peculiarity being the nature of the intake pipe, which can be readily seen on the illustration.

Mercedes has adhered to the firm's usual triangular attachment of rear axle, the driving shaft being within a torque tube. The axle housing comprises two units, each one being a tube and one-half of the differential housing. These parts are machined out of the solid forging and are bolted together centrally, no tie rod being used.

These were among the few cars in the race in which the drive is not taken through the springs.

The four-speed gearbox has direct drive on fourth. There is no geared-up drive.

The engineers have compromised in the matter of streamline body. The radiator is pointed, a scuttle dash is fitted, there is a complete clean cut underpan extending as far back as the rear axle, but no attempt has been made to fit a tail. While this might have been advantageous from the pure speed standpoint, it would make the wheels and tools less accessible.

The gasoline tank is therefore set across the frame, just behind the seats, and back of it is a cradle for two spare wheels. All possibility of puncturing the tank by reason of the movement of the wheels is removed by fitting a triangular tire carrier inside the cradle, and attached to the main frame members.

The gas line is double and external, both lines being connected up to the carbureter, but one of them being shut off. A big hand pump is mounted on the top of the tank with the object of equalizing pressure. The position of the tank and carbureter allows the cars to run on gravity, and when the tank was being filled the motor was not stopped.

There is a series of lockers built around the tank. On

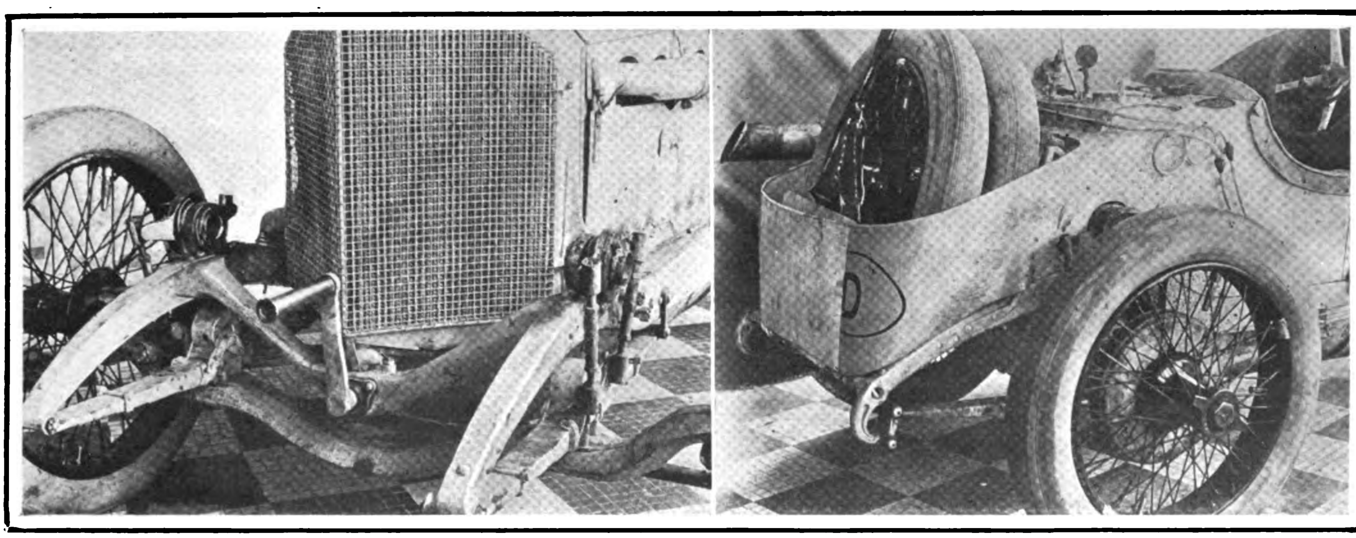

Fig. 5—Front and rear of the Mercedes racers showing how bodies were designed to eliminate wind resistance. The V-radiator was supported at three points on the frame and the underpan is continued to the rear so as to protect all of the car mechanism. The gas tank is entirely concealed between the seat and the compartment for carrying spare wheels. Note the V-shape given to forward edge of the front axle

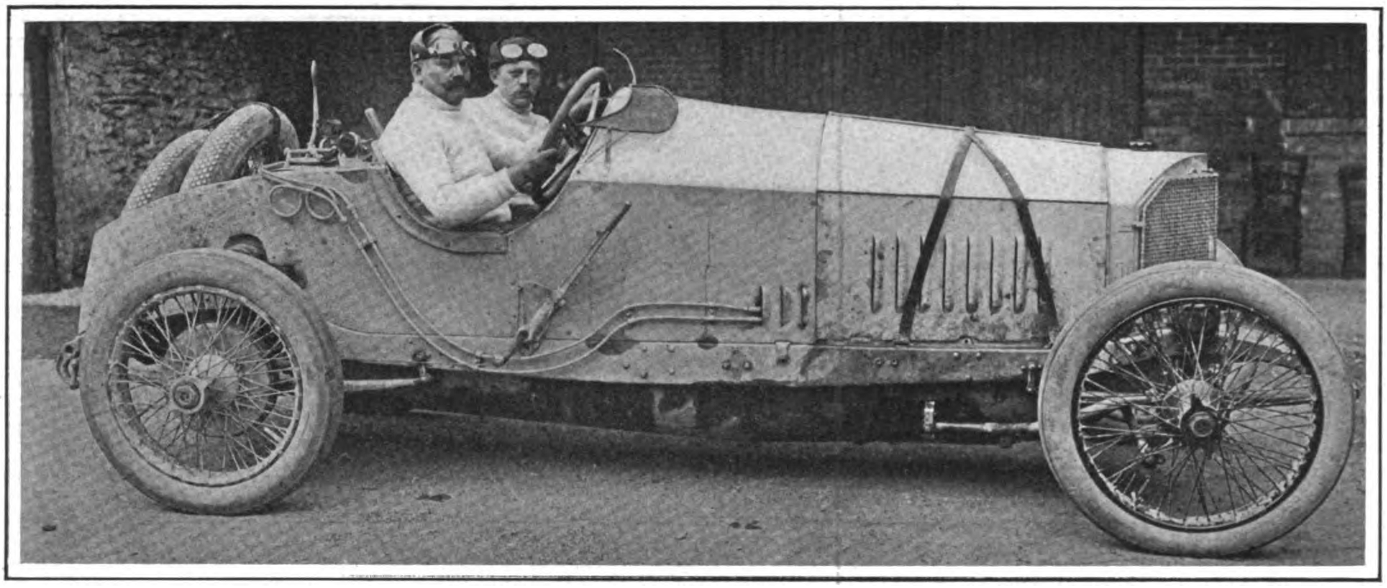

Fig. 6—Side view of Mercedes racer which won first three places in French Grand Prix race showing how the streamline design is carried out from front to rear. The rear springs are underslung and the car mechanism is absolutely horizontal throughout

the left-hand side, just behind the mechanician is a small compartment for spare plugs and other small articles. On the right-hand side, directly behind the driver, is a compartment for a thermos bottle. Some of the men had a flexible pipe attached to the bottle allowing them to drink while driving. In a central position are two holes for the jack and jack lever. Everything is readily to hand, and yet the lines of the car are as clean cut as possible. Under the dash is a small metal box, the front of which carries a set of metal tabs, numbered 1 to 10. The tabs were turned down successively, as laps are reeled off; at half distance they are all turned up again, and then successively turned down until the end of the race.

The Mercedes team ran in the race with Rudge-Whitworth wire wheels equipped with Continental tires, dimensions being 815 by 105 millimeters front and 895 by 135 rear. Lautenschlager changed at half distance as a matter of precaution. Wagner, the second man, ran through without changing at the rear and only changed front as a matter of safety.

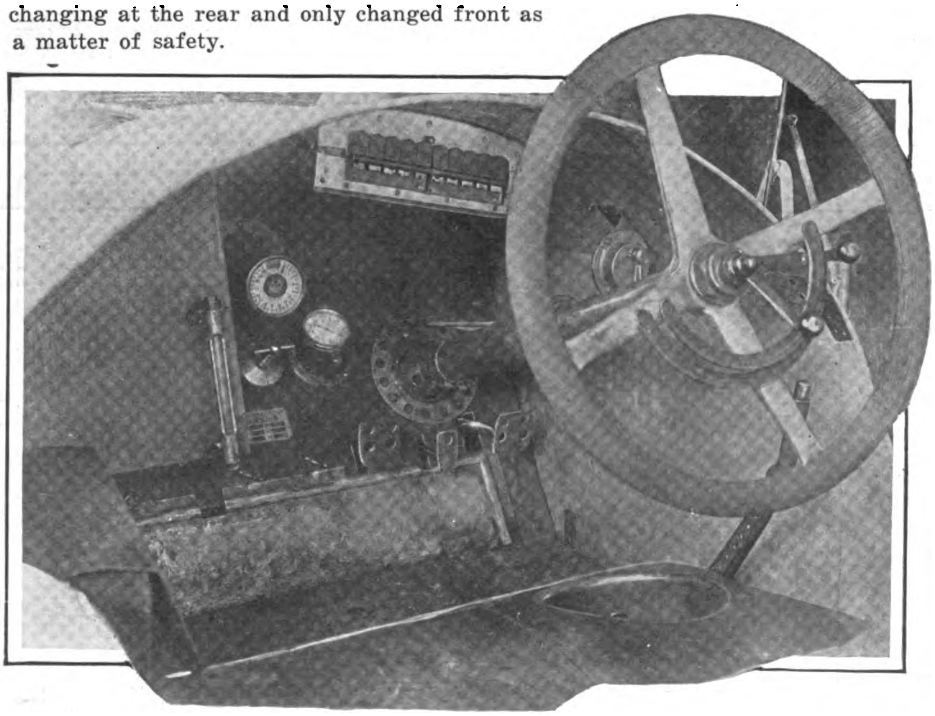

Fig. 7—Dash and control parts on the Mercedes racer. Note the counter box for keeping record of the laps in the race

Not a Spectator Injured—Drivers Only Slightly Hurt

Sporting Commission Reduced Danger To Minimum at the Grand Prix Race

PARIS, July 6—In running this year's Grand Prix race on July 4 on the 23.3-mile circuit near Lyons the element of danger was reduced to a minimum by the excellent precautionary measures taken by the Sporting Commission. At every point where people were likely to congregate the road was barred off by wood boardings. Police and troops were placed at intervals around the entire course.

A new feature this year was the placing of banks of sand or cinders on the outside of all turns and curves on the course. Thus, if a car were unable to get round the probabilities were that it would be arrested by the bank of sand without any damage being done. The sporting committee rented the land on the inside and outside of all the hairpin turns. It was thus possible to put a soldier at each of these points and absolutely prevent any person entering the danger zone.

Not a Single Spectator Injured

By reason of these excellent arrangements there was not a single accident to a spectator and the mishaps to drivers were of a minor nature. Sisz, when overtaking one of the Opel cars partly collided with this latter and suffered a dislocated shoulder. The Opel men were unhurt. Bablot, when maneuvering for a position at the pits, ran his rear wheel over his mechanician's foot. When taking a sharp turn around a wall of rock, Tabuteau struck his rear wheel against a projecting stone. The car was wrecked but the two men were hardly hurt.

Two of the hairpin turns on the course were surfaced with concrete on the top of the macadam. This gave very satisfactory results. The third hairpin turn was in a town and was paved with small smooth granite blocks. The approaching road on each of these hairpin turns was left open for a length of 50 or 60 yards, thus allowing a driver to run ahead if he discovered, on approaching the turn, that his speed was too high to get round in safety.

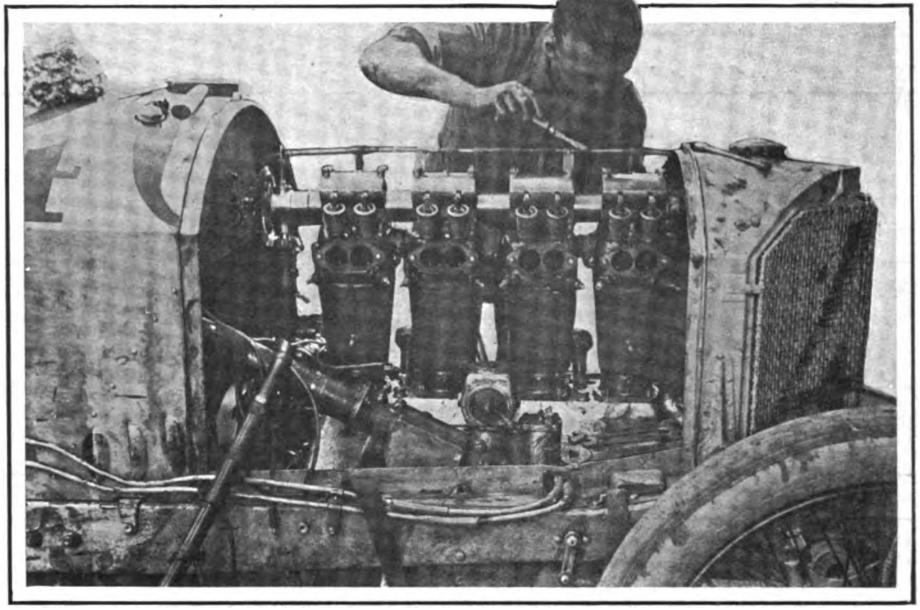

Fig. 8—Partly assembled view of the motor in the Mercedes car. The cylinders are 3.6 by 6.49 inches bore and stroke. In millimeters this is 93 by 165

Mercedes Makes Record

The lap record belongs to Seiler in 20 minutes 6 seconds, which is only a few yards short of 70 miles an hour. Wagner, when given the signal to take up the pace set by Seiler, did a lap in 20:17. The fastest lap done by any of the Peugeot men was 20:20, and as they were pushed to the limit it is evident that they were not as fast as the Mercedes. Duray furnished the fastest lap for Delage in 21:13. Lautenschlager's fastest lap was 20:33, this being when he took the lead from Peugeot. His slowest lap was the first, which he made in 22:31.

In taking account of the average speed it must be remembered that the course was an exceptionally winding one of rather a hilly nature. On the 3 1-2-mile straightaway stretch with a switchback surface the average speed of the best cars was a little more than 100 miles an hour.

Over the measured kilometer, timed in both directions and the average taken, one of the Peugeots did 112 miles an hour. In the trial work some of the Delages touched 124 miles an hour on the fastest portions of the course. In the preliminary trials a Delage averaged 73.9 miles an hour for a single lap, but this average was never made in the race itself.

It is rather difficult to get exact figures on the power obtained from the 274 cubic inch motors, for all manufacturers are not equipped for measuring power at more than 2,800 revolutions. It is certain, however, that several makers obtained more than 125 horsepower, and one maker claims to have secured 135 horsepower at 3,000 revolutions. It will be possible to make closer comparisons when these cars have been seen in the Grand Prix de France, at Le Mans. This is a fast, level course on which several races have been run, and on which the speed possibilities are a known quantity.

Firestone Has Free Library for Employees

AKRON, O., July 20—Following out its efficiency policy, the Firestone Tire & Rubber Co. has recently installed an industrial library that has many striking features, chief of which is that the provision that any one, upon request, may obtain a complete set of books or any other printed matter available on any subject he may be interested in.

Furthermore, the library staff is expected to keep in touch with all employees holding responsible positions and to know what line they are especially interested in. Whenever books or magazines are received along this line, notice is immediately sent to those interested.

A research staff is employed to look through magazines, newspapers, trade journals, etc., and cards are sent to the different individuals calling their attention to items that might be of interest to them.

At regular intervals bulletins are posted and passed around to keep every one advised as to what books are available and what recent additions have been made.

Construction Is Factor in Victory

Best Cars and Men Won Grand Prix—Mercedes Covered 30,000 Miles in Tests

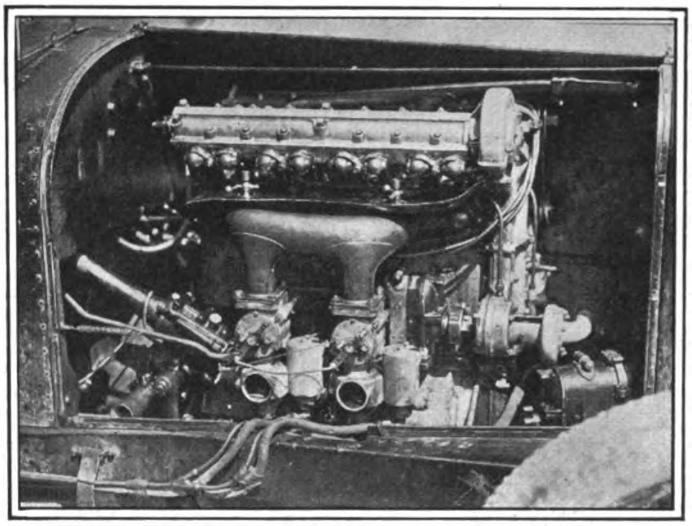
PARIS, July 6—Although it may be a severe blow to French pride, the admission has to be made in Paris that the best cars and the best men won the 1914 Grand Prix at Lyons last Saturday. There is a slight attempt in certain quarters to ascribe the Peugeot defeat to tires, but this excuse will not stand serious examination and is not even put forward by any impartially minded person.

When the race started five firms were picked out as likely to furnish the winner. They were Delage, Peugeot, Mercedes, Sunbeam, and Fiat. It was early discovered that Delage could not be relied on. During the practice period there had been a certain tendency for these motors to backfire into the carbureter, and one caught fire during the official practice. The valves are a new type with double cams giving a positive closing as well as a positive opening. It was thought that the backfiring was caused by an imperfect seating of the valves, and as a matter of precaution the timing was changed the night before the race. There was no time to try out this modification, and it was only when the cars had started in the race that it was seen to have been a most serious mistake. This move came as a great surprise, for Delage has the reputation of being the most careful race organizer in Europe.

Sunbeam experienced mechanical difficulties on two of the cars—broken piston and broken connecting-rod—and the third had some tire and plug trouble. Fiat also met with valve and plug trouble.

As to the others in the race, they were generally suffering from a lack of detail preparation and did not look upon themselves as capable of getting the first place.

Much of the success of Mercedes in this race may be attributed to the very thorough manner in which the race was entered and prepared for. As soon as the rules were announced the German factory put in the maximum number of five cars. The drivers were sent to study the roads as early as last January and two entirely different types of cars were built. One set of cars had six-cylinder motors built to the maximum piston displacement and the other set were those



Sunbeam motor. Note spare magneto and two carbureters

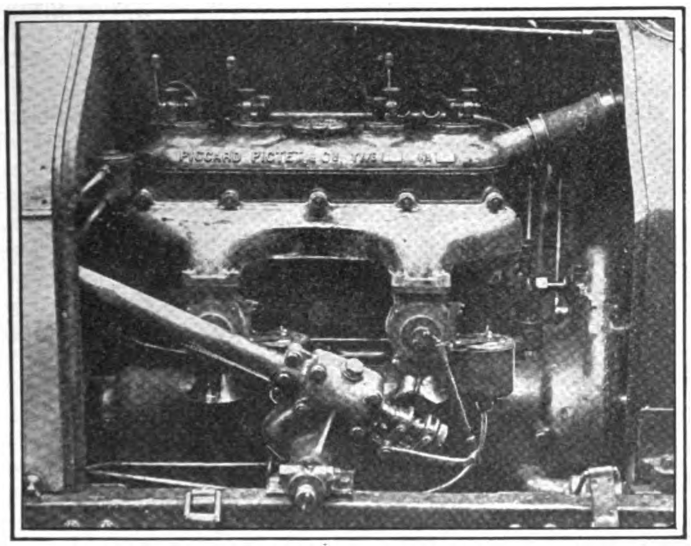
which ran in the race, and had four-cylinder motors. Both sets were completely ready 2 months before the date of the race. In addition to the five cars run in the race, a sixth reserve car was prepared and was even weighed in with the others so that it could start if an accident happened just before the race. Further, a complete chassis without motor was brought to the racing headquarters, to be used in case of emergency, a week before the start of the race. It is estimated that 30,000 miles were covered in road tests before the Mercedes team came to the starting line.

The general organization of the race was also cleverly worked out. The numbers of the cars were decided by the drawing of lots, but this drawing affected the cars only and not the drivers. Thus, at the last moment it was decided to let Sailer, a newcomer and an untried man, take the first of the Mercedes cars, and orders were given him to sacrifice everything in an attempt to run the others to death. Boillot was particularly picked out for punishment in this combination and he fell into the trap in an unusually simple manner. He started No. 5, with Sailer, No. 14, getting away 2 minutes later. As soon as the Frenchman was informed that Sailer had set up a faster pace he opened out with an eye to grandstand applause and when the German passed him on the road, his only thought was to regain the leading position. Sailer overturned after covering nearly six laps, but the German trick had been played, for Boillot had been punishing his car and himself and the three other Mercedes men, after lying back at the outset, were given the order to spurt ahead and maintain a killing pace for Boillot.

The Germans, too, showed superiority in their pit arrangements. They started out with tires of 135 millimeters section on the rear, whereas the Peugeot men used 120 millimeters, and were so undecided as to whether steel studs or smooth treads should be used that some of them made three changes in order to get comparative results. Lautenschlager made one stop for tire changes at the fourteenth lap, replacing all four wheels as a matter of precaution. It was noted that the tires were evidently satisfactory for the entire race, but having received orders to change at this point Lautenschlager carried them out.

Many Racing Precautions

Detail preparation of the racing cars was a strong feature with all of the teams. The external polish and varnish, equal to that given to show models, was merely an indication of the minute care bestowed on the essentials. The Mercedes used a double gasoline line, both completely connected up, but one of them shut off by means of a cock. This duplication was general. Sunbeam, in addition, had all copper pipes, whether for gasoline or oil, inside thick rubber tubing. These two firms carried the pipes on the outside of the frame members, with a filter and water separator so placed that it could be reached by the driver without getting from his seat. Delage wrapped all oil leads heavily in adhesive tape to prevent breakage. These arrangements were so thorough that not a single car was stopped by reason of oil or gasoline lines.



Piccard-Pictet sleeve-valve motor. Note two carbureters

Streamline Efforts General

Where streamline bodies were adopted the protection of the under organs followed as a natural consequence. Fiat and Peugeot did the most original work in this connection. The former firm had a narrow radiator, a tapering hood, a scuttle dash and a cigar-shaped tail with the gasoline tank carried inside it. The streamline effect was perfect, for an underpan was fitted from the radiator to back of the rear axle, giving a circular section practically at every point of the car. The exhaust pipe, instead of being external, was kept under the hood, being passed under the dashboard and finally brought outside the underpan and carried horizontally to the rear.

While this car had the most highly refined streamline effect, some of the advantage was lost by having to carry the spare wheels one on each side, between the front and rear wheels. Peugeot got over this disadvantage by lengthening the tail and setting two wheels vertically within it, a hump being formed on the tail to accommodate them.

Mercedes recognized the value of a streamline body by using a pointed radiator and having a complete unbroken underpan, also wind cutters for the front axle. Back of the driver's seat, however, there was no attempt at cutting down resistance. The tank was set across the frame and back of it a cradle for two spare wheels. Within the frame work around the gas tank there were separate compartments for a jack, hammer, levers for jack, and even a pocket for a drinking bottle containing a small quantity of spirits. Delage had a similar general arrangement at the rear, the drinking bottle being replaced by a fire extinguisher.

Front-Wheel Brakes Made Good

For the first time in automobile racing front-wheel brakes made their appearance on Delage, Peugeot, Piccard-Pictet and Fiat cars. Although the winning cars were not equipped with this type of brake, there can be no doubt that braking on all four wheels was decidedly advantageous. The grandstands were on a slightly down grade and as this stretch was preceded by a straightaway down grade, there was a tendency for drivers to approach their pits at too high a speed. Several of the drivers with cars having the ordinary types of brakes overshot their mark and either skidded violently or caused the back wheels to dance in a fantastic manner in their efforts to pull up. The cars with front-wheel brakes invariably stopped in a shorter space than those with only rear and differential brakes, and they never showed any tendency

to swerve from their course. On one particular occasion when Goux was chasing Lautenschlager, he was able to pass him on a long winding down grade entirely by reason of his more efficient braking. This incident was visible from the grandstands.

Delage, Peugeot and Piccard-Pictet used internal expanding brakes of equal size on all four wheels, the brakes being fully enclosed. Fiat had smaller brakes on the front than on the rear, those on the front being exposed. Delage braked on the wheels by means of pedal, the two front and the two rears being balanced. Connections were by means of steel cables.

Practically all the cars in the race had provision for adjusting while in motion. The adjustment screws were brought through the floor boards, conveniently placed for being operated on by the mechanic.

Gasoline Consumption Low

No official account was taken of the amount of fuel and oil consumed, but it may be taken that the consumption of gasoline was at the rate of 13 to 15 miles per gallon.

The Fiats, owing to their low weight, ran nearly 16 miles to the gallon and carried the full quantity of fuel aboard when starting the race. No other teams attempted to run through without a stop for gasoline, although the feat was possible. It was considered that the disadvantages of the big tank and great weight at the outset outbalanced the advantage of being able to run through without a stop.

No Oil Supply Needed

No car took on oil during the race. The amount carried was considerable, but this was more with a view to maintaining the lubricant at a low temperature than because of the quantity consumed.

Mercedes carried 3 gallons of oil in the base chamber and between 4 and 5 gallons in the reserve tank set across the floor under the legs of the crew.

Delage had about the same quantity in the base chamber and an equal amount in the dashboard reserve tank, this latter being constantly in communication with the motor.

Fiat and Peugeot had 5 gallons of oil in a tank entirely independent of the base chamber. The Fiat supply was mounted in a tank under the scuttle dash, vents being cut in this latter to direct a current of air on the tank. Two pumps were made use of, one of these pumping oil out of the base chamber, and the other drawing the lubricant from the tank and delivering it to the main bearings.

The Peugeot system was similar in its main features, with the difference that the tank was set across the frame under the driver's seat.

Sunbeam adopted the same general arrangement as Peugeot.

Castor Oil Everywhere

Castor oil was extensively employed. One firm used pure castor oil for not only the motor but for the gearbox and the rear axle, there being about 3 pints for the gears and a pint and a half for the axle. As this quantity was sufficient for the race, it is evident that the joints were well made.

With the exception of the Piccard-Pictet sleeve-valve motors, none of the engines smoked. Even at the starting line, with nearly forty cars lined up, there was an almost complete absence of smoke—just a mere puff as some of the cars went away. On a 23-mile course it is difficult to find traces of oil drippings. Opposite the pits, where most of the stopping and starting was done, there were no indications whatever that oil had leaked.

Poor Lever Arrangement Spoils Brake Efficiency

The Automobile Engineers' Forum

Ex-President of S. A. E. States That, for Best Operation, "Hook-Up" Must Be Carefully Worked Out—Criticizes Poor Brake Lining

DETROIT, MICH.—Editor THE AUTOMOBILE—A great many problems enter into the successful operation of brakes in service. It is frequently the case that the brakes *per se* are blamed for poor action when the trouble is not in the brakes themselves, but in the arrangement of the side rods and levers running from the brakes to the operating pedal or hand lever. The best of brakes will not give satisfaction unless what we term the "hook-up" is carefully and correctly worked out, and this varies with different conditions.

Brake Lining Is Often Poor

Another source of trouble is in the brake lining itself. There is a multitude of linings on the market, but only a few of them give all around satisfactory service. Very frequently a brake lining which is good when it is brand-new will quickly become either glazed, so as to reduce the coefficient of friction, or become impregnated with oil, likewise reducing the coefficient of friction. Satisfactory brake lining must be one of very long life which will wear only very slowly so as not to upset the original correct brake adjustment and the brake lining should have no very great reduction in coefficient of friction when it is moistened with water or covered with oil.

It is our opinion that on the whole brake sizes on the majority of cars today are ample. There are, of course, exceptions, but we believe that today automobiles on the whole are equipped with brakes of adequate size for the work required of them.

With proper material in the brake lining, proper design of brake and proper design of brake connections, the customer should have very little occasion to touch his brakes during the first season's use of the car.

Connections Do Not Receive Attention

I believe we can say, however, that one of the features of automobile design which receives less attention than it warrants is this matter of brake connections, between the brakes themselves and the operating levers. Sometimes it looks as though the expert designing engineer had spent all his time on the other features of the automobile and left this virtually important detail to some inexperienced draughtsman. The proper arrangement of levers and rods will warrant the most careful attention on the part of an experienced man, and very frequently an apparently slight change will make what appeared to be unsatisfactory brakes give proper satisfaction.— H. W. ALDEN, chief engineer Timken Detroit Axle Co.

Thinks Celluloid Disks Make Best Headlight Dimming Devices

CHICAGO, ILL.—Editor THE AUTOMOBILE—The writer has investigated and looked at so many dimming devices that are intended to prevent the dazzling of the eyes by glaring headlights that his brain is dazzled on the subject. It is a hard matter to eat your cake and still have it, and that is just what the motorist wants in reference to headlights. The police departments in some of the cities compel him to dim his headlights, and still he wants a bright light that can be used on dark streets and in the country.

We have a very efficient inspection board in Chicago, composed of three of our police heads, and it seems that a very equitable, fair and efficient inspection plan has been devised by this board.

Tested in Dark Room and on Road

First, the lamp with dimmer attached is submitted and a written application filed by the owner or maker. This lamp is tested in a dark room in the basement of the City Hall. If found at all meritorious, a road test is given the next evening in one of our parks on the Lake shore. If the second test proves satisfactory, the owner or maker of the device is given a certificate which he is allowed to reproduce.

On the subject of dimmers, our police board have decided that a metal shield or hood over the outside of the glass is 90 per cent. efficient but 10 per cent. deficient on account of a glare being thrown into pedestrians' or motorists' eyes when the automobile travels up a short incline or over a hill.

The two-bulb proposition, one being placed at the upper front edge of a parabola reflector, passed inspection, but is likely to be knocked out on account of it being regulated from switch on the dash board, it being contended that the driver can use his glaring lights and then when he approaches an officer, throw the switch over to the bulb that is out of focus and thus bring about an argument between himself and the officer. Furthermore, there is nothing to prevent a car owner from substituting a large candlepower bulb for the 4-candlepower bulb which has been authorized, and very few police officers can tell the difference.

The frosted glass has passed inspection and is satisfactory, likewise the celluloid disk, which is specified on certificate number 1.

Two or three firms submitted shutter devices that seemed to give the desired results when they were open and when they were closed, but they rattled and are expensive to make and attach.

A cone-shaped cup just large enough to clear the diameter of the bulb within the parabola reflector was tried out and proved O. K. at the test last fall, but the same has not been submitted in the recent test. The shape of this cup is like a flower pot or a Turk's cap.

Another device made of celluloid and working like a window curtain with two strings to each lamp running back of the dash board within reach of the driver was tested out last fall, but not this spring, the principle of this device being that the driver could drive it down over his headlamp or release it, and it would recoil on its roller at his pleasure. This, being seat-operating, would probably not pass at the present time.

Glass Subject to Breakage

Another firm submitted sample lamps where 2 inches of the outer edge of the glass had been frosted and 5 inches center being clear glass with a small hole drilled in the center and a ¼-inch diameter stub bolt fastened in this hole extending forward of the glass about ½ inch. Over this stud a 5-inch diameter metal disk would be attached and held in place by a knurled nut. This device passed inspection, but it was proven in the original test that the glass was subject to breakage on account of the hole, and to the further fact that the average user would draw up the nut too tight, thus forcing the saucer shaped metal disk against the glass, causing the same to crack. This, of course will be a serious objection to a device of this kind, for a motorist would be up against it if he should break his lamp glasses in putting on the disks when he approaches a town. You understand, this saucer-shaped disk is intended to be removed when a motorist drives in the country.

Glare Thrown Over Hill Crests

Another firm submitted a convex molded and frosted glass, the convex being about 4½ to a 9-inch diameter, being about two to one. Commencing in the center of this convex glass and extending down to the bottom edge and at a width of about 2½ inches is a clear spot. Through this clear spot the rays of light are projected forward and down on to the roadbed, and the effect and result is satisfactory when the car stands on level road. When the car travels up a short incline, or over a hill, the glare is thrown into the eyes of the pedestrians or motorist, just as it is when the metal shield or hood is used.

Another device or glass is called the double lens or prism. This is a molded glass and the front and back surface of each glass is a series of small raised half circles, representing half marbles of different sizes, arranged in circular form. In the center of this molded glass there is one large marble, 2 inches diameter. Arranged in circles around this center piece and reaching to the outer edge are a number of circles of marbles, commencing with the size of about ⅜-inch diameter next to the center piece, and increasing to about 1 inch diameter on the outside circle. This same effect is worked out on the inside of the glass. These glasses have not passed up to the present writing, although they have been on test several times and, according to the writer's opinion, they never will pass, for with a 16-c.p. bulb, there appears to be about ten thousand glaring streaks of light, for it appears that each marble intensifies the light and adds to the glare.

Celluloid Disk Easily Attached

The Monarch celluloid disk has met with the approval of the most critical automobile men and motorists. It can be attached or detached to a lamp in a jiffy, either inside or outside of the door, is non-destructible, is light and will not rattle, and the expense is nominal. This celluloid disk is covered by patent No. 824,603, and can be attached to the outside or inside of a door in various ways. One is to use the prongs and bend them over the door frame, then close the door with the prongs on the inside, thus clinching them between the door frame and the body of the lamp. Another way is to fasten them on the inside of the door next to the glass by the use of the prongs, and a third way is to solder three little clips on to the edge of the door frame, right next to the glass, and then nip off the prongs and spring the short ends into these little clips.

Illinois has just passed the 99,000 mark for automobile licenses, and over 1000 licenses have been issued to dealers in the state. Each dealer's license represents at least three machines, so that it is a safe bet that we have over 102,000 operating automobiles in the state right now. Of this number, authorities estimate that 55,000 are in Chicago and immediate suburbs. Figuring that about 60 per cent. of the automobiles have glaring light, the probable consumption of dimmers in Chicago will be about 33,000 pairs.

In addition to the device mentioned above, of course, you are aware that several firms are manufacturing rheostat or series switches to decrease the voltage of lamps, but these have been depreciated on account of it being possible to operate them from the seat.—H. N. Fowler, president, Fowler Lamp & Mfg. Co.

Fits Brake Shoes Steel Against Steel Like Locomotive

PHILADELPHIA, Pa.—Editor The Automobile—Your editorial on brakes, in the June 18 issue, and C. V. Beck's article on the same subject, are both in the right line. Automobile brakes have been one of the articles neglected from the very beginning, and the reason why they are fitted in duplicate today is because they are not reliable.

The remedy is not another set of the same kind, but change the kind.

Almost every vehicle in use from locomotives to log wagons, is fitted with shoe brakes, and they are not only reliable, but when they are off a glance at them insures that they are free from the wheels. The ordinary band brake drags most of the time, and Mr. Beck is quite right, that gasoline bills are much higher because of the use of the band brakes. Automobile builders have been adding much weight and complication around the hub of the wheel, trying to get in wide powerful band brakes, when it seems only reasonable that the rim of the wheel is the place for the brake. Here is where our roller drive shines again. The drive is applied to the rim of the wheel, and the brake is applied to the driven member. The result is we fit shoe brakes steel against steel, just like a locomotive. We get a most superior driving effect, positive clearance, and practically no chance for failure. Those interested in the best form of brakes will do well to consider the shoe brake in use everywhere, and as fitted to Duryea cars.—Chas. E. Duryea.

Censures Complication of Light Cars and Cyclecars

GALVESTON, Tex.—Editor The Automobile—Although not a real automobile engineer, I would like to talk to some of the designers of our modern automobiles, especially to the men who are planning and building the so-called light cars and cyclecars. The avowed purpose of these men is to turn out cars that will be light, easy on tires, small consumers of fuel, and generally simple in construction and operation.

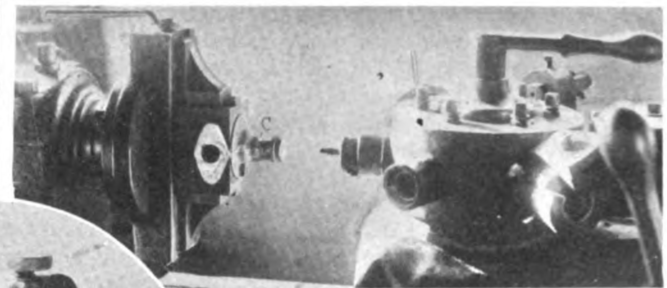
Yet one of the first things these engineers do is to complicate their would-be simple car by the addition of such complications and weight adding devices as starting and lighting systems, which are as useless as they are expensive and unhandy on a car of this type.

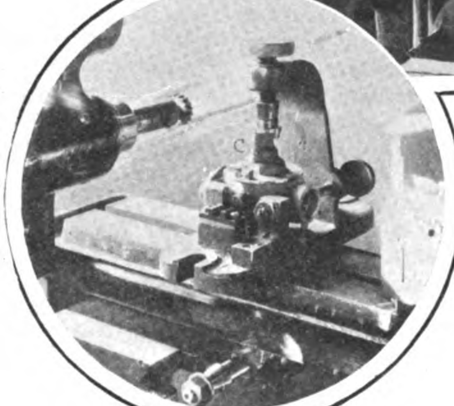
If a man has a big, heavy machine with a high-compression motor he probably needs a starter, and a lighting system is well worth while, but with a little car and a small motor, what is the use?—E. F. Benson.

Accuracy—The Holley Byword

Many Parts of Holley Carbureters Manufactured Under Limits of Accuracy to .001 Inch—Some Parts Have .0005-Inch Limit

SPEED and accuracy in Holley carbureter production are secured by jigs, fixtures and inspection. Thousands of parts must follow each other with the uniformity of the shots of a gatling gun. Each must be alike. The same amount of time should be spent on each, and when all the parts come together in the assembly room they should fit with perfect interchangeability.





In the Holley shops. A casting in position on a monitor ready for several operations such as drilling, turning and threading. Note the special fixture for quickly and accurately fixing the piece in the revolving head of the lathe

How a milling operation is performed on the bowl of a Holley carbureter. A special form of jig quickly positions the piece on the bed of the machine in correct relation to the cutter

Three Manufacturing Departments

Three departments enter into the actual manufacture of a carbureter. They are the foundry, the machine shop and the assembly. These three departments form a Y-shaped scheme. The foundry and machine shop are the two branches and the assembly the root. The two branches must flow smoothly into the root and the entire layout must be symmetrical. The machine shop and the foundry should work together and finally join at the root of the Y in a smooth, steady stream from the assembly department into the shipping room.

The whole scheme is similar to a railroad at a given point of which two branches come together, forming the Y. Two trains start at the same time from each end of the Y, are coupled together at the junction and pass on to the terminal. The starting point is the entrance of raw material into the plant, the stations along the way are the inspection stops, the junction is the entrance to the assembly department, and finally the terminal is the shipping room.

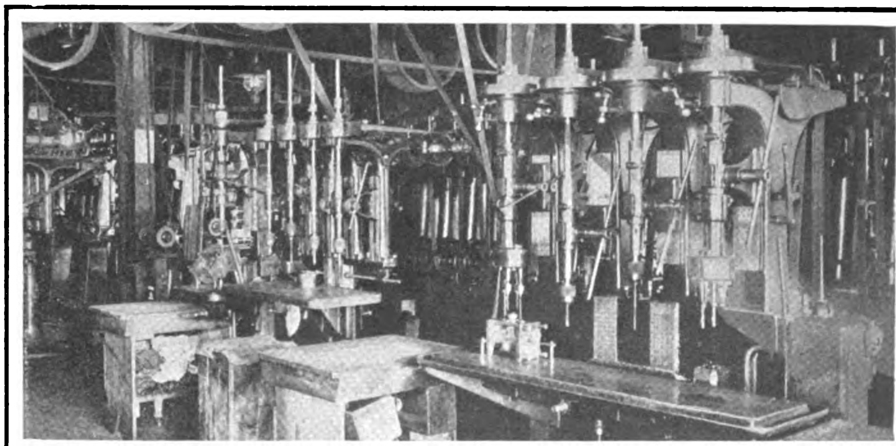
To expedite the passage of the train there are the shortcuts of manufacture, including the jigs and fixtures in machine work, the efficient motions of the workmen, the employment of high-speed machines, etc. All these parallel the fine road equipment of a railroad, shortening the time spent on the road, at each of the inspection stations along the way at the point of juncture at the asembly plant and finally into the terminal shipping room.

The carbureter plant of Holley Bros. Co. has recognized these principles of accuracy manufacture, linking with them quantity output. From the plant 1400 to 1500 carbureters emerge daily, and sometimes when demand is very heavy the working schedule is stepped up to as high as 1,800 a day.

Yet this quantity side of it seems to be secondary to accuracy. Perhaps the secrets of Holley success may best be summed up by saying that the copious use of jigs, good inspection methods and efficiency are at the bottom of it all. The Holley carbureter to be ready for the market must undergo a large number of careful inspections in its progress through the plant, and many of these hold the limits of accuracy to .001 inch, one or two parts, such as nozzles, etc., being deemed so important as to require half a thousandth-inch limit. The parts are subjected to jig treatment for nearly every operation, and such methods are reflected in the product.

The visitor to the Holley plant sees many examples of productive efficiency; sees how time is saved wherever possible without sacrificing accuracy; sees everywhere the results of specialization on the making of a single product.

The embryonic Holley instrument is a form of alloy which comes to the



A part of the Holley machine shop where drilling of the many different sized holes in the carbureter is taken care of with the greatest accuracy and speed. These multiple-spindle drills are molded in connection with jigs which assures correct position of the holes plant in the shape of 25-pound "pigs" of even analysis. These pigs have this composition: copper, 85 per cent.; lead, zinc and tin, each 5 per cent.

Seven or Eight Pigs Melted at Once

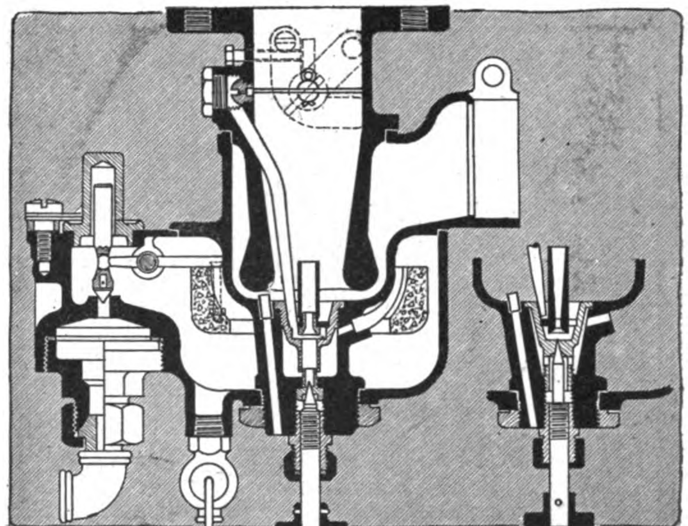
The pigs are melted in crucibles which are placed in oil-burning furnaces. There are half a dozen of these occupying one end of the foundry. Seven or eight pigs are placed in each crucible and heats are made three times a day, this giving time for making of a number of molds between each heat, and everything is thus in readiness for the pouring when the metal is reduced to a molten condition. It is carried to the molds in ladles which are mounted in long-handled holders to protect the two men doing the pouring from the excessive heat. This is in accordance with regular foundry practice.

There are fourteen Tabor molding machines in the foundry. These are very efficient machines for putting up flasks, one man being able to average a mold every 3 minutes. In the making of carbureters most of the pieces are small, hence the molding plates used contain from six to 120 pieces, all connected by little channels so that the metal can flow from one to the other. For instance, one plate has on it eight strangling tubes, another twenty-five pet cocks, and so on. Thus, when a flask is filled with molten metal, a number of these small parts are cast at the same time.

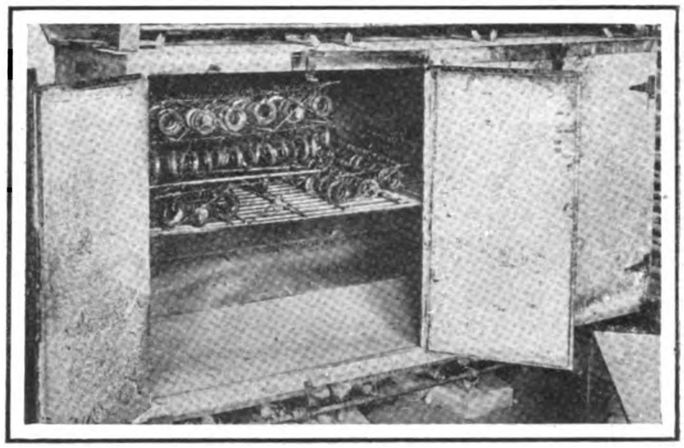
Patterns Are Carefully Guarded

These multiple-pattern plates, which are of uniform size so as to fit into the molding machines, are very expensive, and hence in the Holley foundry there is a regulation type of vault, in which they are kept. This has 18-inch fireproof walls of safe construction, so that in the event of a fire the large outlay for patterns would not be lost. To facilitate the procuring of any desired pattern plate, each is numbered as well as the racks on which they are arranged. A card index is kept of the patterns, and it is a simple matter to refer to this index to locate any one of the hundreds of plates in the racks.

A number of the castings used in the making of the carbureter require cores. These are simply baked sand forms, which are placed within the moulds to make hollow centers to the pieces when cast. It keeps the core room busy making these for the foundry. Here there are sixteen core makers, each provided with an individual bench. Special core forms are provided, in which the cores are made, then placed on racks to dry before being placed in the core ovens.



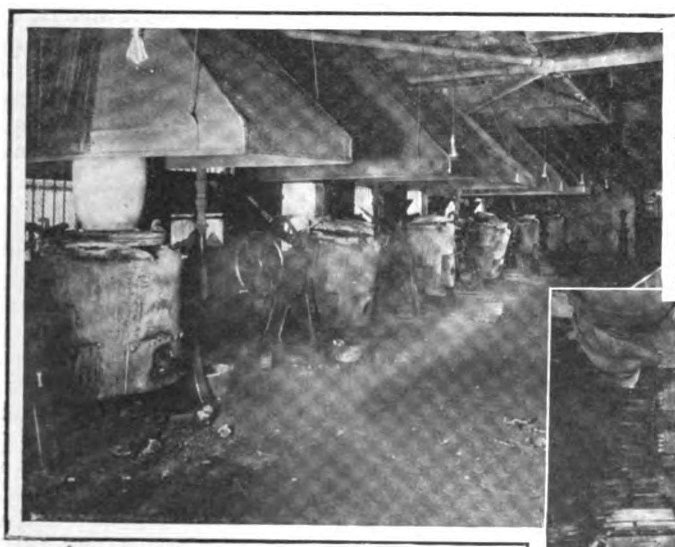
Sectional view of the Holley carbureter showing complete assembly



The cork float baking ovens. After receiving a coat of insulating varnish, each float is baked for 24 hours at 210 deg. F. It is then again varnished and the same baking repeated. These ovens have a capacity of 2,000 floats per day

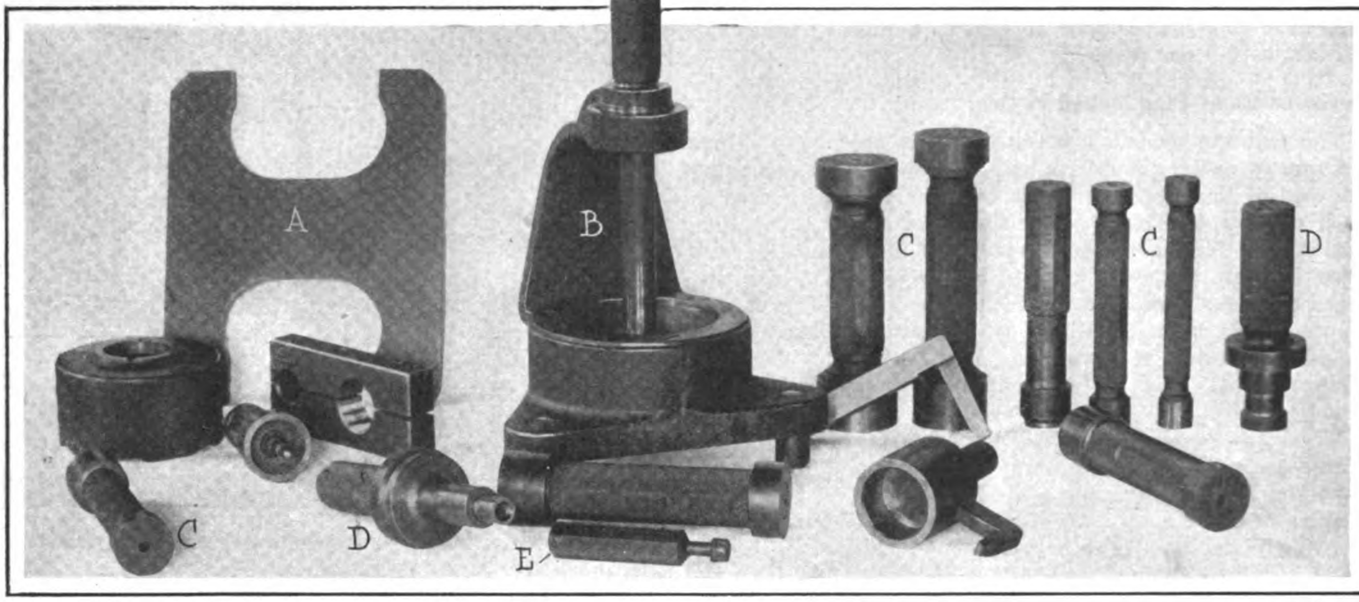
Crude Oil Used in Core Ovens

These ovens use crude oil for attaining the baking temperature of 300 degrees Fahrenheit. There are eighteen compartments to the oven structure, and in them the cores are baked for lengths of time, dependent upon their size. Small cores require but 10 minutes to be hardened sufficiently while some of the larger ones take as much as 1½ hours. When sufficiently baked, a core is almost unbreakable.

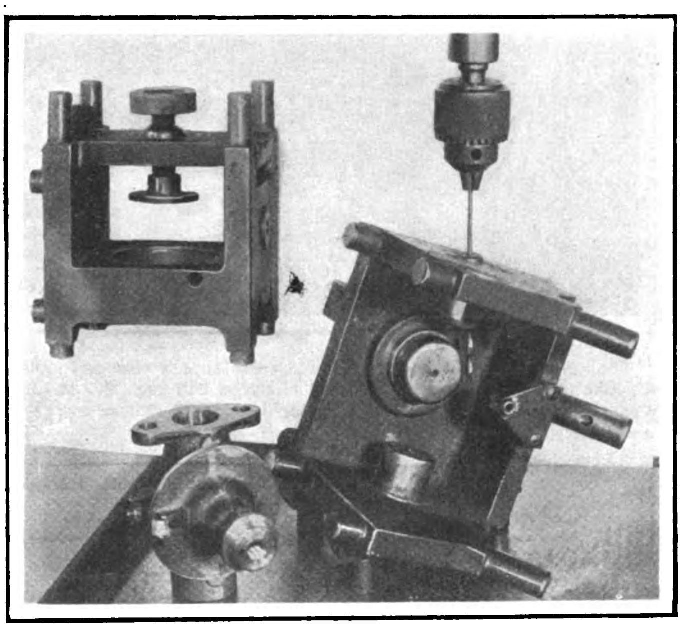


A corner of the Holley foundry where all carbureter castings are made from molds

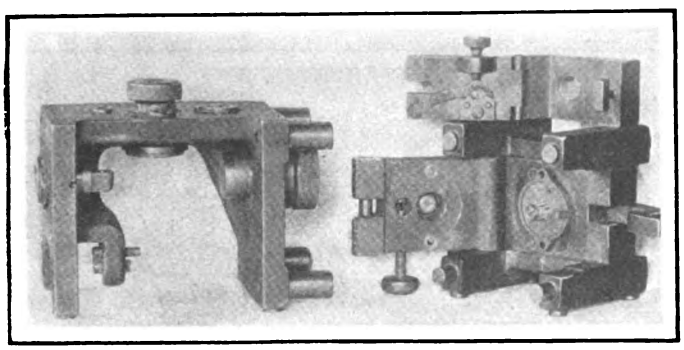
The furnace room of the Holley plant. Six oil furnaces melt the metal in crucibles from which it is carried in ladles to the molds



An array of gauges for testing various dimensions of the Holley carbureter to a thousandth of an inch. Most of these work on the "Go" and "No Go" principle. A—External diameter or width gauge. B—Distance gauge. C—Plug gauges for internal diameters. D—Depth gauges. E—Thread gauges. The rest are special gauges for testing certain parts.



How a jig works. The piece is first fitted within it and clamped, thus locating the drill points. The drill may then be inserted and the operation performed. Such jigs are very costly, this particular one, which is an average affair and not specially complicated, costing the Holley concern $250



Jigs abound in the Holley plant. These are typical of the great number of costly devices of this kind for the accurate positioning of holes and the like in the various parts of the carbureter. The piece is fitted in the jig, which then locates the drilling positions, making it an easy matter to drill the various holes and to make every piece a counterpart of every other similar one

Compressed Air Hammer Loosens Sand

After pouring, the molds are allowed to cool before the sand is broken away from them. Some pieces with cores in them are troublesome in that the core sand is hard to remove. The old method was to rap the pieces with a hammer until the sand was sufficiently loosened to come out. This is a slow process, and the Holley foundrymen have devised a quicker and better method. The pieces are hung on a standard and a small compressed-air hammer held against them long enough to completely loosen the sand. This takes but a few minutes, and one man does the work which would require three men in the old way. Efficiency here scores again.

Having cleaned them of sand, the next step is to shear off the "runners," which separates the individual pieces. They then go to the sandblast, where all foundry dirt is taken off, and are made ready for machining, as any dirt or sand would injure the tools. A New Haven sand blast machine of barrel form, 36 by 46 inches, takes the place of four men at this casting cleaning work. The barrel or drum into which the pieces are placed rotates at two revolutions a minute, and into it are injected sand blasts under a pressure of 80 pounds per square inch. The strong blast of sand, coupled with the rotary movement of the barrel, smoothes and cleans the castings thoroughly. The machine can handle 1,200 pounds of castings at one time, they being subjected to this treatment for 20 minutes.

Finishing Castings by Hand

The castings next visit the grinders, where the fins are taken off, after which they go to the burring bench, where such projections as cannot be reached by the grinding wheels are filed away by hand.

The foundry processes are now complete, and the rough parts go from here to the machine shops for finishing. These are the most extensive part of the plant, and it is here that accuracy of production comes into its own.

On graduating from the foundry, the parts are placed on specially constructed wooden racks which are so made as to admit of piling one rack on top of another. A bank of them is placed upon a truck and the whole transferred to the machine shops. These racks form an important part of the production, in that the pieces as they advance from one machine process to another travel in them, they being their constant companions until assembly is in order. This makes for much quicker handling and better routing efficiency all around.

Much of the machine work is done on lathes, although, due to the great number of holes of varying sizes required in a carbureter, drilling is also a very important part. There are in all about 100 back-gear monitor lathes and some fifty multiple drills, to say nothing of the numerous other types of machine tools.

Lathe processes are standard in every way, the workmen exhibiting remarkable skill in making accurate pieces. They are all provided with the proper gauges to check their work. To see that his tool is cutting accurately, each workman tests every tenth piece he makes. This testing is only preliminary, however, as a very careful inspection by trained inspectors takes place later on, as we shall see.

Multiple Drills Play Big Part

The multiple drills are one of the biggest factors for rapid production in the Holley plant. In each part of the carbureter there are a number of holes of different sizes to be drilled. Wherever possible a single multiple drill is set up to take care of all of this drilling in any one piece. Each spindle is provided with one or more drills, depending upon whether the position of the casting when ready for any particular hole to be made will admit of others being drilled at the same time. If this is the case, a multiple head is used, which turns several drills from the same spindle. In this case all are pressed down into the casting at the same time.

The drilling is arranged in the best possible sequence; that is, figured from the standpoint of making every move of the piece count, the work is done in that order which will require the least shifting around of the piece following each successive drilling operation. This saves time.

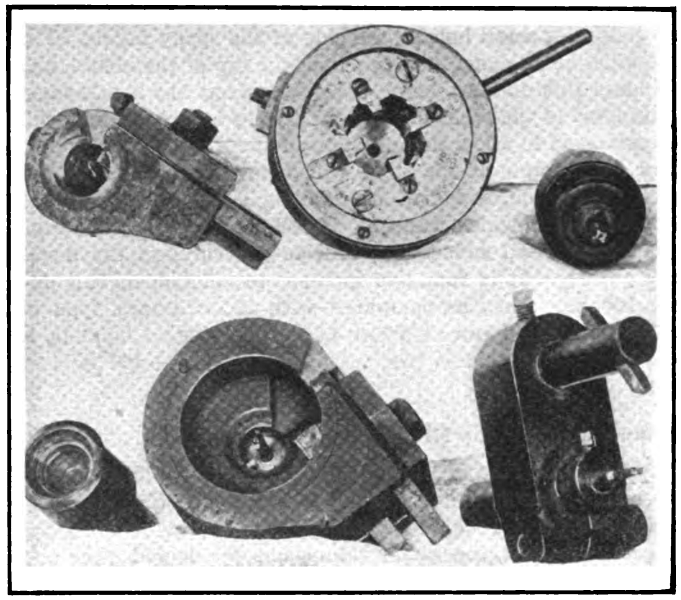
Special Jigs for All Parts with Holes

No drilling is done without the use of jigs. There is a special jig for every part requiring any holes to be made in it, which insures absolute uniformity among the pieces. By their use the operator has but to put the drill in the right hole in the jig, which insures its correct location in the casting within.

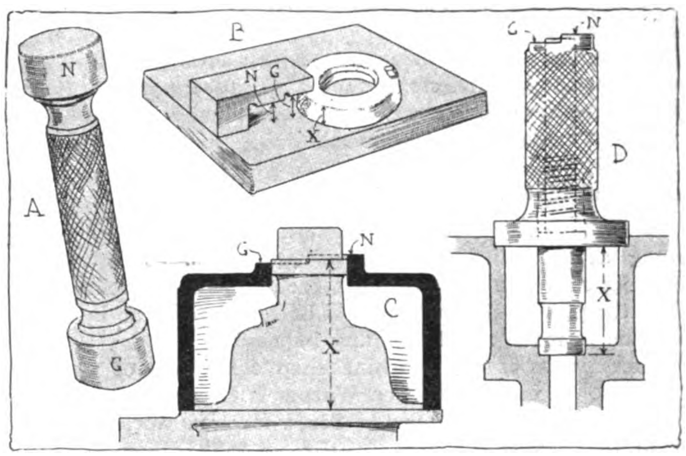
Many special drilling processes have been developed. For instance, one special jig allows for the simultaneous drilling of four holes $\frac{1}{8}$ inch in diameter. All these holes are of different depth, varying from 1.4 to 2 inches, and all are at different angles in the casting. A multiple head on the drill spindle aids the jig in this.

A Foolproof Jig

There is a special jig for elbows, to insure the two drillings at right angles coming together within the casting. There is a special drill for mixing chamber caps, the jig taking care of these drillings at once. Another jig is called a foolproof



Some of the special tools devised by the Holley Bros. Co.

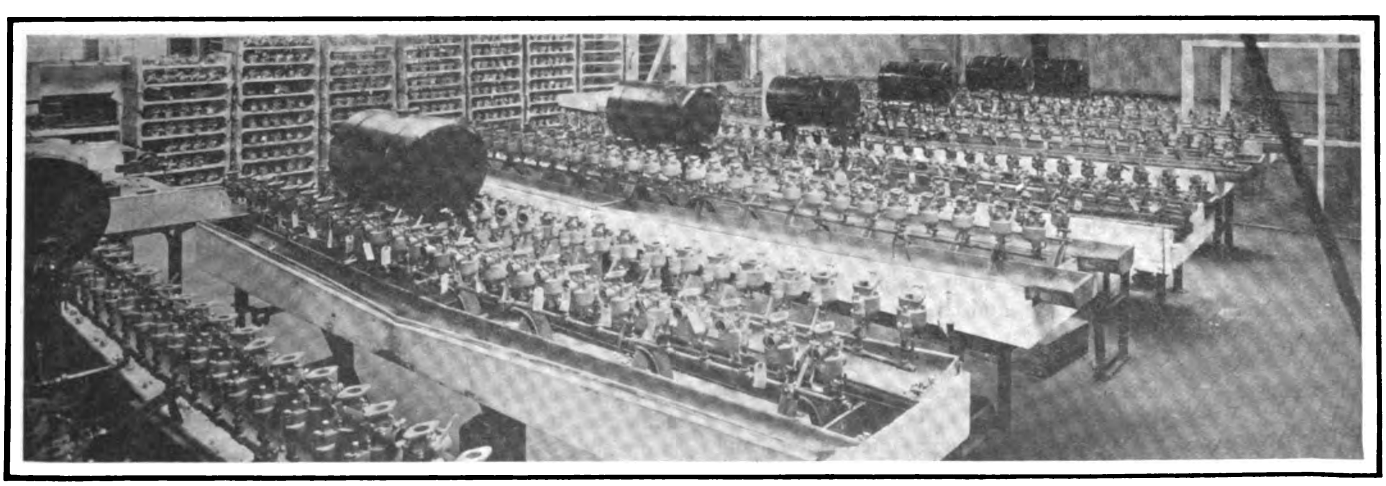


A—This is a plug gauge for internal diameters. The gauge end G should pass through the hole, while the end N should not

B—Float thickness gauge. X—Height of float which, if correct, should pass under that position of the gauge marked G and which cannot go under part N, which is only slightly lower

C—External height gauge. The piece is laid on the flat surface and gauge placed over it. Distance X must be accurate and should be between limits G and N

D—Depth gauge for determining accuracy of distance X. When shoulder of gauge rests on upper part of hole, lower end of plunger or gauge must rest on lower part so that upper end of plunger is within limits G and N



Testing rack where for 2½ hours each finished carbureter is tested for leaks and proper float level affair, because the operator cannot go wrong. This is used for drilling a small hole in the side of the spray nozzle. The hole must be an exact distance from the top of the nozzle, and to insure this distance being absolute correct the nozzle must be inserted to the right distance in the jig before the hole will be uncovered to allow the insertion of the drill.

As an example of the steps which have been taken to get quick production, one drill for making a 1/16-inch hole has been installed, which runs at 10,000 revolutions a minute. This great speed causes the drill to get through the metal very quickly. It is found to increase production of this one hole 100 per cent., as compared with the ordinary type of drill which would run at about 3,500 revolutions. That is, it goes through the pieces just twice as fast, due to the greater speed.

Teamwork Speeds Up Drilling

In some cases the drilling of a part is very rapidly done by two men. One man loads the jigs while the other does the actual drilling. To operate this way, two jigs of the same kind are required, the loader taking out the drilled piece and replacing it with another ready for drilling while the other man is at work drilling the piece in the other jig. Sometimes one loader can keep two drill men busy, provided the drills are arranged so that each can be readily reached from the loading table.

Because of these various schemes, developed through specialization, the drilling is done with great rapidity. One multiple drill, which is about an average, handles 800 castings a day and drills nine holes in each.

All Jigs of Macadamite

All the jigs are made of macadamite, an alloy which is as strong as steel but lighter than aluminum. This makes handling easy and is therefore a factor in rapid production. Were the jigs of steel they would be so cumbersome in some cases as to make rapid handling impossible.

Other parts of the machine shop take care of special processes. A bank of sixteen Warner & Swasey hand screw machines produce small parts. Screw machine work is cared for by four National Acmes, two Brown & Sharpe automatics and two Cleveland automatics, which are ever operating with human intelligence and superhuman speed.

After machining, the burring department burrs off any sharp edges due to cutting tools. Then all finished holes are plugged and the pieces sandblasted to even up the color. Then before they are touched they are lacquered with an air brush and dried. This insures a uniform color over the entire piece and gives a finished appearance.

Tool Department a Big Saving

Besides this room there is also a tool stock room where all tools not in use are kept. When a workman is put on any operation he obtains an order signed by his foreman for the taps, dies, jigs and other fixtures needed for that operation. All these are kept together in one pan, and the tool stock keeper needs only to get the particular pan bearing the required operation number. This saves much time in providing the men with the needed apparatus, which must be returned after the job is completed.

Finished parts after lacquering go to the inspection department, where twenty experts pass upon them. Preliminary inspection has already been made, and the pieces come to this final inspection with traveler system tags upon them. On these tags are noted the date of making, the workman's number and operation number. Thus there is a complete check on the work.

Limit gauges, snap gauges, plug gauges, micrometers and other special testing apparatus is at the command of the final inspectors. Variations of over .001 inch are not tolerated and spell rejection. The low-speed plugs have an even more rigid test. They must have an accuracy to plus or minus .0005 inch. Some of the special gauges and the methods of using them are shown in the illustrations.

Check on Inspectors Also Kept

On the examination of each piece coming to him the inspector is required to make a notation on the inspection report. He must enter the part number, its symbol, the number called for in the order, the number received, the department or sub-department from which received, the number passing inspection, the number returned for proper finishing, the number too imperfect to admit of refinishing and which must be scrapped, and the inspector's number.

Following this rigid inspection, parts are remanded to the stock room, from which they are requisitioned for assembly as needed. Only enough stock to fill an order can be drawn.

The progressive assembly system is employed in the putting together of the Holley instruments. The trays of parts are placed at the beginning of the line of assembly benches. Each man has his part to do, after which he passes the instrument on to the next man. One puts the levers on, the next drills cotter holes, succeeding ones put in the cotter pins, assemble strangling tube, spray nozzle, elbows, inlet needle seat. At the other end of the line of assembly benches they go into waiting trays again.

Meanwhile, in another part of the factory, the cork floats are being made so as to meet the partially assembled instruments at the final assembly benches. This float manufacture is an interesting process. Nine girls are engaged in the work. The cork is first turned into its correct form, which is followed by an inspection for thickness and diameter. The first of these inspections requires a special gauge which has two heights—a "go" and a "no go" height. The cork must just go under the correct height, but not under the incorrect one.

Double 24-Hour Baking at 210 Degrees F.

After the float is manufactured to size it is given a coat of special insulating varnish by hand brush. It is then baked for 24 hours at 210 degrees Fahrenheit. Varnishing is now repeated and the float again baked under the same conditions. This varnish process coats the float with a preservative which is said to withstand almost an acid test.

Following the two varnishings, the lever for float regulation is added by a girl who uses a power screwdriver. With the lever in place, the final varnishing and baking for another 24 hours takes place. If baked less than this time there is danger of the varnish peeling off, and if baked longer there seems to be little advantage. For this baking process there are six gas ovens which have a capacity of 2,000 floats a day.

Having united the carefully made floats with the other part of the instrument, assembly is complete and the carbureter is ready for testing with gasoline for leaks and fuel level. The test racks for this process have room for 780 carbureters, each of which is connected to the gasoline supply contained in a 5.gallon tank mounted on the test table. Below the racks on which the finished carbureters are mounted there are troughs which catch the gasoline overflow and return it to another tank ready for re-use after straining.

Each instrument undergoes this leak and level test for 2½ hours. After standing with gasoline in it for this length of time a level gauge is applied. This is a pointed plunger gauge which rests upon the top of the float chamber as a positioning point. When in position the point should just escape the level of the liquid, but when the plunger is pressed down the point should touch this level. This admits of very little variation.

Having satisfactorily passed this examination, the instrument goes to the polishing room, where the bowls are buffed as an added touch to appearance.

Then the carbureters are mounted on another set of leak and level testing racks and supplied with gasoline. Following this final make-sure test they are ready for shipment.

Germany's Elaborate Statistics

Latest Official Data on the Production and Utilization of Motor Vehicles in German Empire, with Interesting Figures on Traffic Troubles and Enforcement of Legal Responsibilities

OFFICIAL statistics with regard to motor vehicles in circulation in Germany on January 1, 1914, and motor vehicle traffic from October 1, 1912, to September 30, 1913, have made their appearance. Distinctions are made between (1) automobiles for the transportation of persons, and these are in this rendering of the statistics termed Motor Cars, (2) motorcycles, which comprise vehicles with a saddle for the driver, not more than three wheels and a weight not exceeding 150 kilograms (in case of electric power the weight of battery not included), (3) motor vehicles for the transportation of goods, which are here termed Motor Wagons, and (4) motorcycles for the transportation of goods, which are here termed Motorcycle Carts.

NUMBER OF MOTOR VEHICLES IN USE IN GERMANY

Jan. 1, 1913		Jan. 1, 1914
49,760	Motor Cars	60,876
20,325	Motorcycles	22,457
7,704	Motor Wagons	9,739
123	Motor Cycle Carts	100

The leading figures are given in the brief list above. From this it is at once noticed that the increase in motor cars for 1913 is only 11,116, which figure thus represents the production in this class of all the German automobile factories plus importations but minus exportations and the discard of old vehicles. [Exports reach the sum of $24,000,000.—ED.]

Motorcycles show the considerable increase of 2,132, which is probably to be ascribed to the introduction of sidecars, as 1910, 1911 and 1912 showed a decrease in this classification in comparison with the number in use on January 1, 1910.

The increase in motor wagons is substantial, but relates more to delivery wagons and light trucks than to the heavier type, as appears from the weights of the vehicles, as scheduled later in this account. Load capacity usually exceeds weight.

Motorcycle carts number only 100, while in 1907 they numbered 254, and have dwindled to insignificance as a class. The explanation is probably that the three-wheeled vehicles used for delivery purposes or other transportation of goods now weigh more than 150 kilograms and are classified under motor wagons.

Among the observations of general interest to which the figures of the census give rise in the matter of traffic accidents there is one which seems to clash with commonly accepted belief, to the effect that motorcycles are much less dangerous than the other forms of vehicles.

Out of the total number of motor cars those which were implicated in traffic troubles have dropped steadily from 30.1 per cent. in 1908 to 17.8 per cent. according to this year's figures. The motor wagons in this respect show a percentage of 17, which is not a betterment on previous years on the face of the report. It is thought that the longer hours during which motor wagons are operated per day and their greater weight offset their lower speed in the matter of the liability to accident for each individual wagon.

The motorcycles show the low percentage of 1.1, which is about the same as for previous years. In other words only 1 out of every 100 motorcycles gets into traffic trouble each year. No clue is given to this comparative freedom from accidents in the motorcycle class, but it may be surmised that it is due to three main factors: Motorcyclists ride little in the crowded streets; they are as a rule persons of athletic inclinations and skill, and they are about on the same level as pedestrians and do not so easily overlook them.

Chart 1 gives the number of motorcycles and of motor cars registered each year since 1907. The increase in motor cars from year to year since 1908 is seen to have varied considerably and has come down to 22.8 per cent. for the past year. The motorcycles which represented more than 60 per cent. of the total in 1907 now represent only 26.9 per cent., while their absolute number, 22,457, is slightly higher than ever before, after some retrogression in the

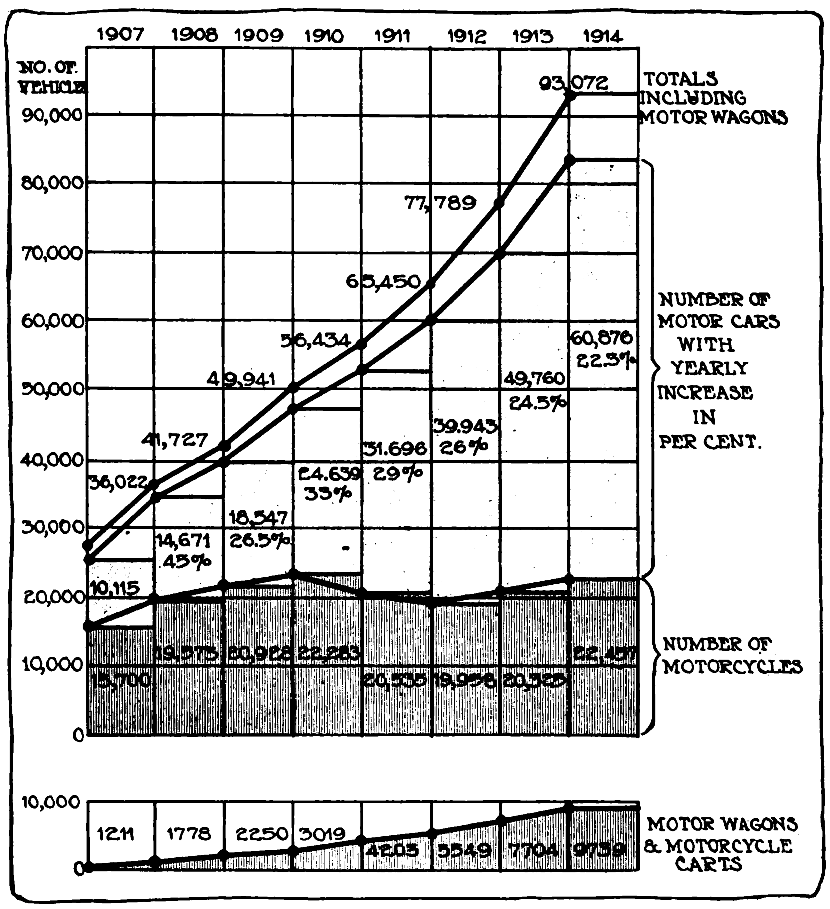


Fig. 1, A—Number of motor vehicles in circulation on January 1 of each year since 1907

Fig. 1, B—Motor wagons and merchandise carts for same period years 1911, 1912 and 1913. Sidecar attachments are gaining. The motor wagons and motorcycle carts are shown separately underneath the main chart and their influence on the totals is indicated again by the top curve in the main chart, showing the total of all motor vehicles for each year.

Power of Vehicles Steadily Increased

Chart 2 shows the distribution of motor cars according to horsepower rating, from which it appears that the increase in numbers is greater for the more powerful cars than for those rated below 8 horsepowers. In reality the tendency to higher power must be still much more pronounced than the figures indicate, because these take no cognizance of the advancement in construction, by virtue of which the actual horsepower is from two to three times greater than the rated one, which was not the case in the earlier years included in the chart figures. With regard to the reading of the chart it may be noted that, as one class of vehicles is superimposed upon the previous lower one, it is not the inclination of the curves to the horizontal which shows the increase within each class, except in the lowest one, but the inscribed figures and the forms of the spaces between curves, while the top curve shows the total increase in the ordinary way by its angle of rise.

Chart 3 shows similarly, but on a larger scale, the distribution in power classes of the motor wagons, the motorcycle carts being omitted. It is noticed that the motor wagons below 8 horsepowers which once constituted 42.6 per cent. of the total now represent only 20.7 per cent., besides being equipped with better motors having a much higher power reserve than formerly, and that the wagons in the 16 to 40 horsepower class now make up 46.7 per cent. of the total.

This is largely due to the subsidizing of heavy trucks to form a reserve for the army. But hereafter the army will use trucks as small as 3½ tons capacity.

Locations Favorable to Trucks

From the statistics referring to the distribution of the vehicles among the component provinces and states of the German empire, which are not here reproduced, it is noticed that the motor wagons represent 10.5 per cent. of the total number of motor vehicles in the empire as a whole but that certain districts utilize motor wagons to a considerably greater extent. In Hamburg and in Bavaria they form thus 17.2 per cent. of the total and in Württemberg about 14 per cent.

Out of the 9,639 motor wagons of this year 6,105, or 63.3 per cent., weigh less than 2,500 kilograms; 1,400, or 14.5 per cent., weigh between 2,500 and 3,500 kilograms and

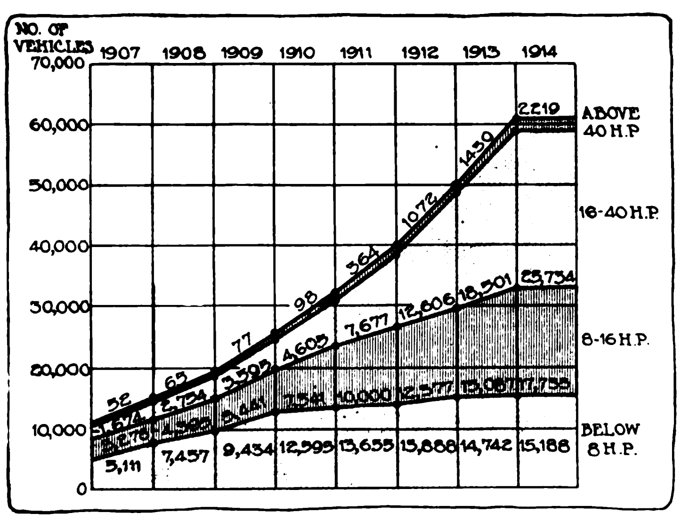

Fig. 2—Census of motor cars classified according to their horsepower, showing that popular preference runs steadily to higher power

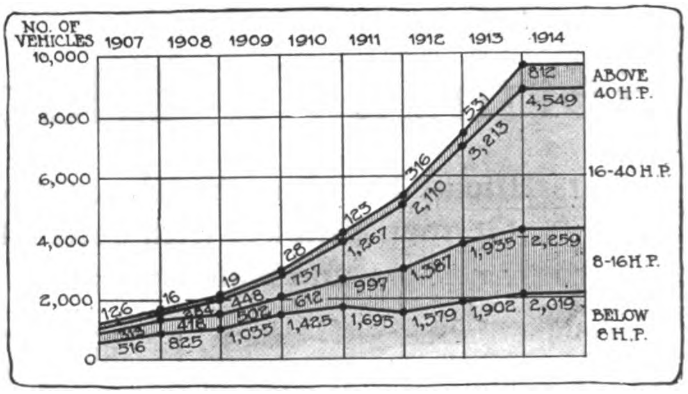

Fig. 3—Census of motor wagons, including trucks, classified by horsepower

2,134 represent the heavy truck class, weighing more than 3,500 kilograms.

How Motor Cars and Motorcycles Are Utilized

The German authorities inquire about the purposes for which motor cars are mainly employed by their owners, and information on this point is given in Charts 4 and 5 for the past year. It is understood that the motor cars which are listed as employed mainly for trade purposes are also occasionally used for mere pleasure, and that the obverse also holds true, but the division gives a clue to the incentives for purchase and the average mode of utilizing the vehicles. By comparison with figures given for previous years the utilitarian uses of motor cars are seen to be gaining slightly over the pleasure purposes. Only the figures for the past year are here shown.

In the available tables of figures no distinction is made between motor cars and motorcycles, and it is these figures which are represented in Chart 4. The most interesting question, as to how many motor cars are employed in Germany at present for sport and pleasure purposes, can be answered only by eliminating the motorcycles. This is done in Chart 5 on the supposition that one-third of the vehicles used in trades and commerce, for professional purposes and by public officials are motorcycles. In this manner it is found that only 22,464 motor cars are used chiefly for sport and pleasure, while 6,426 are used by physicians, surveyors, ministers, lawyers, etc., in their vocations, 21,624 to expedite

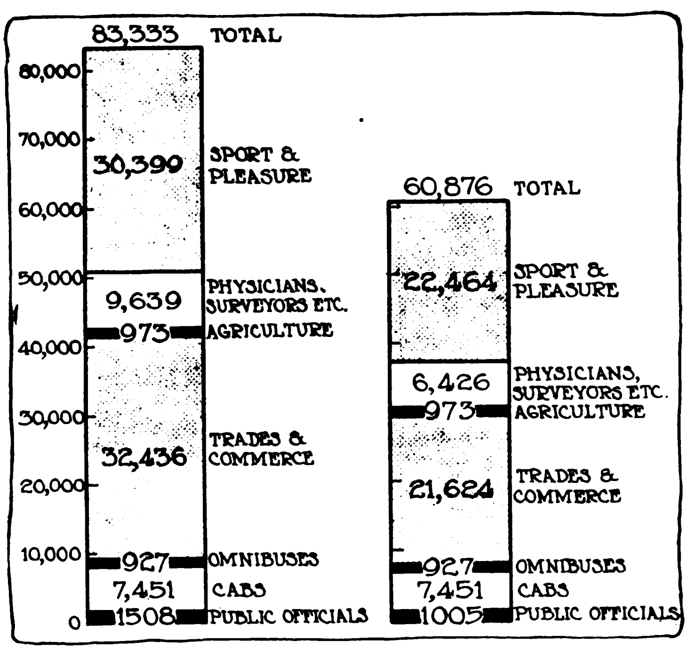

Fig. 4—Uses of motor cars and motorcycles, grouped together. Fig. 5—Uses of motor cars; motorcycles being eliminated by estimate

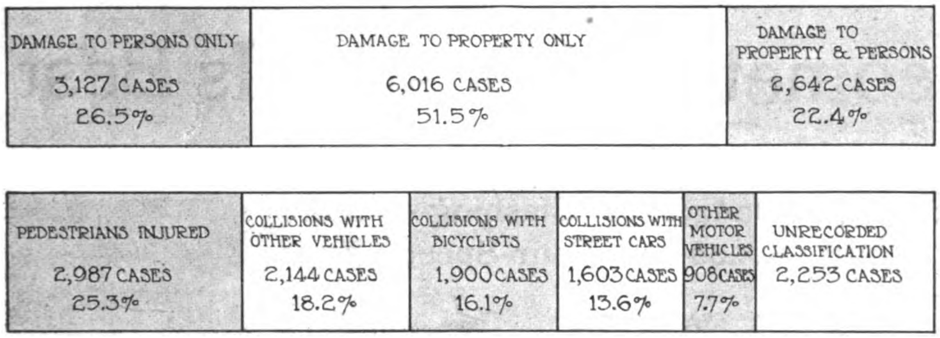

Fig. 6—Effects and nature of 11,785 traffic accidents involving 12,772 motor vehicles

trades and commerce through the transportation of individuals engaged in these pursuits, 7,451 as taxicabs, 927 as omnibuses, 973 in agriculture and forestry and 1,005 by public officials.

On the other hand this way of reckoning leaves 503 motorcycles for the use of officials, 10,812 for trades and commerce, 3,213 for professional persons and 7,935 for sport and pleasure, the total of which tallies with the official count of 22,457 motorcycles in all.

The classification of motor wagons according to their uses is more summary. Out of the total of 9,739, including the 100 motorcycle carts, 8,799, or more than 90 per cent., are listed as employed for commerce in general, while 761 are used by public officials, 81 in agriculture and forestry and 98 for diverse purposes.

International Traffic and Touring

During the year, from October 1912 to October 1913, 24,647 non-German motor vehicles crossed the boundaries of the empire. Among them were 1,522 motorcycles and 232 motor wagons. The increase over the previous year was 2,321, making 10.4 per cent. but this increase is the smallest for the past six years, indicating that Germany is not gaining in favor as a touring ground for people of other nations. Against the 232 motor wagons which entered Germany stand 148 motor wagons for the previous year, showing a substantial increase in the international trade traffic. Among the non-German vehicles 7,685 came from France, 7,300 from Austria, 2,962 from Switzerland, 2,268 from Holland, 723 from Great Britain and 342, or 1.4 per cent., from the United States. The foreign traffic was concentrated to the extent of about one-half in July, August and September.

Destructive Incidents and Accidents of the Motor Vehicle Traffic of Germany, October 1, 1912, to September 30, 1913

During this period there came to official notice 11,785 accidents—or, as they are more accurately termed, destructive incidents—in which motor vehicles were involved. The number of motor vehicles implicated in these incidents causing damage to persons or property was 12,772, as in 948 of the cases two motor vehicles were concerned in the accident, in 16 cases three of them, in 1 case four and in another single instance five of them.

The detail figures show plainly that each motor vehicle becomes a safer member of the traffic as their number increases.

If there were as many motor vehicles in the German traffic as there are pedestrians and other kinds of vehicles, the relatively small number of cases in which one motor vehicle collided with another—the exact number of these cases being 908—would go far to indicate that speed in itself is a small factor in causing accidents, since the relative speed is doubled where a collision of two rapidly-moving motor vehicles is concerned. In the statistics the probable reason for each accident is given in only about half of the cases. Excessive speed accounts for 1,103 cases, being 9.4 per cent., lack of skill or caution accounts for 2,626 cases and the action of third persons or the inattention of the injured persons is given as the reason in 1,391 instances.

Some data on the nature and cause of the incidents are given in Chart 6. Of the 12,772 motor vehicles implicated in them 233 were motor bicycles, 10 motor tricycles, 10,835 motor cars, 1,636 motor wagons and 4 motorcycle carts. In 54 instances the nature of the vehicle was unrecorded.

Only 78 of the vehicles were known to be domiciled in other countries than Germany, but in 259 cases the home of the vehicles remained unknown.

The total number of persons injured was 6,313, among whom 503 were drivers of the motor vehicles, 1,107 occupants of the same and 4,623 outsiders. The killed were in all 504, among whom 34 drivers, 61 passengers and 409 outsiders. The total of 6,817 killed and wounded represents an increase of respectively 62 and 771.

The damage to property foots up, according to the estimates, the sum of 2,771,688 mark (nearly $700,000) out of which 83 per cent. falls on destroyed and injured motor vehicles, a small amount on property carried in these and 16 per cent. on the property of outsiders. As compared with former years the losses fall more on the motor vehicle owners and less on outsiders. The average damage to property, when any was inflicted, amounted to 320 mark (about $80), and this amount is somewhat higher than in other years, mainly owing to the higher cost of the motor vehicles.

Gearset of Geometrical Design Is Best

Makes Gearshifting Easier Than the Arithmetical Design with Less Danger of Clashing — More Power on Third Speed of Four-Speed Type

By W. C. MARSHALL

Part II

INTERMEDIATE gear ratios are determined in an arbitrary fashion by taking for a four-speed car the figures which are arithmetical means of 35 and 7.4 viz. 16.6 and 25.8 the engine being supposed to run at a constant speed of 1,000 revolutions per minute. This gives the points *c* and *d* and enables the lines to be drawn for second and third speeds.

How Motor Speed Changes

Let us analyze the change in motor speed when the change speed lever is moved through all four positions.

Starting from first or low speed from rest the clutch must slip some for the motor speed must not drop below a certain figure which we will say is 400 revolutions per minute. The clutch engagement cannot then be final only after the car has reached a corresponding speed which from the figure is found to be 3 miles per hour or an acceleration of

$$\frac{3 \times 5280}{60 \times 60} = 4.4 \text{ feet per second.}$$

The speed still accelerates until the motor is turning 1,000 revolutions per minute and the clutch is thrown out of gear in order to change to second speed. As the car is running 7.4 miles per hour the motor must slow down to a speed corresponding to the car speed of 7.4 miles per hour (which will keep up due to the inertia), in order to slip in the second gear.

The motor speed will have to be 445 revolutions per minute.

As soon as the clutch is let in the motor speeds up to 1,000 revolutions per minute which means a car velocity of 16.6 miles per hour. To make the shift to third speed the clutch is released and the engine slowed down to a speed sufficient to correspond to the third ratio, namely 616 revolutions per minute.

Speeding up to 25.8 miles per hour at 1,000 revolutions per minute, and changing to fourth speed reduces the engine to 741 revolutions per minute which increases to 1,000 revolutions per minute when the car is running 35 miles per hour.

The actual gear ratios are 14, 6.33, 4.04, 3.

From the above we see that for the third speed change to high or fourth the drop in motor speed is much less than for other changes.

Evidently this is not logical.

It is necessary to equalize the reductions of speed and reduce them to a minimum in order that one speed change shall not be more difficult than another.

On the majority of vehicles in fact it is stated to be easier to pass from third to fourth than from first to second. For heavy, slow vehicles, the intermediate speed should be equalized in order to equalize the wear and reduce the motor speed as little as possible after the car has once started. The problem resolves itself into the equality of lines *A E*, *H F* and *D G* as shown in Fig. 5.

Let V_1, V_2, V_3, V_4 be speeds corresponding to a fixed motor speed V and let V^1 equal the uniformly reduced motor speed.

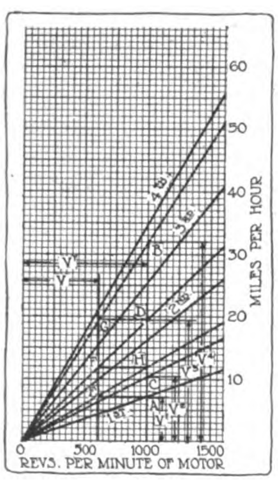
The similar triangles of the Fig. give $\frac{V^1}{V} = \frac{V_1}{V_2} = \frac{V_2}{V_3} = \frac{V_3}{V_4}$ from which $V_2^2 = V_1 V_3$ *and* $V_3^2 = V_2 V_4$.

Substituting, $V_2 = \sqrt[3]{V_1^2 V_4}$, $V_3 = \sqrt[3]{V_4^2 V_1}$ *and* $V^1 = V \sqrt[3]{\frac{V_1}{4}}$

In the case of three speeds only we have $V_2 = \sqrt{V_1 V_3}$ and $V^1 = \sqrt{\frac{V_1}{V_3}}$

Less Shock on Teeth

By this method the intermediate speeds would be the geometrical means of the extremes instead of the arithmetical means. One advantage of



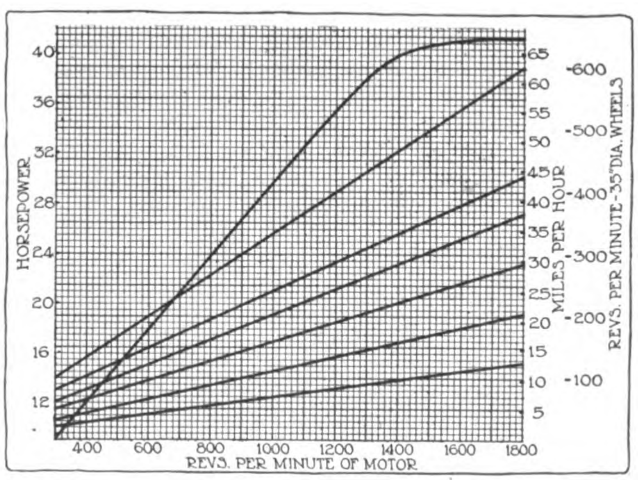


Fig. 5—Left—This is a diagram showing the changes in motor speeds in shifting gears in a geometrical gearset, and the line A-E representing the change in motor speed when shifting from first to second, and the line F-H when shifting from second to third, and the line D-G when shifting from third to fourth, are practically all of the same length, this being the desirable factor obtained in a gearset with geometrical gear ratios

Fig. 6—Right—This curve is to prove graphically the superiority of the gearset with geometrical gear ratios as compared with another gearset with arithmetical ratios. It accomplishes this proof by bringing together all of the factors entering into this question. On top is shown the horsepower curve of a motor 4 1/8 x 5 1/4 inches, and below this are given curves of gear ratios for both arithmetical and geometrical gearboxes, these being used with a car having 35-inch wheels and traveling at a speed up to 35 miles per hour. Further, this diagram is used to work out the power at the clutch of the car, as shown in Fig. 7

this method would be to diminish the shocks to the teeth, from the fact that variations between motor speed and car speed would be reduced to a minimum mean. Is there need to proceed in this manner for light, rapid automobiles? In the face of the general practice of the first method it would hardly seem so. Nevertheless if one considers that in these vehicles one establishes the fourth speed with a certain margin and that there is advantage in making use of the second as little as possible, it will perhaps be found advantageous to increase the ratio between fourth and third in such a way as to extend the field of action of the third. Nothing would then prevent bringing the second toward the first and arriving at the conclusion of our method by different considerations.

In the case of the car cited above, the speeds of the car would be 7.4, 12, 21.2, 35 miles per hour by the geometrical progression. This would give change in motor speed from first to second (assuming revolutions per minute of motor at the car speed for the miles per hour given) of 385 revolutions per minute. From second to third 434 and from third to fourth of 390 which is nearly a constant speed when compared with 555, 384 and 259 for the arithmetical ratio.

The minimum revolutions per minute of motor would be 566 as compared to 445 in the former case.

If the ratios of gears were 14, 8.5, 5.1 and 3, the minimum revolutions per minute during gear shifting would be 590 and would take place during the shift from third to fourth. From first to second the motor would drop from 1,000 to 605, from second to third the drop would be from 1,000 to 600. This shows an improvement at low speeds.

If it is desired to shift gears as soon as possible and not allow the motor to drop in speed below 400 revolutions per minute, the first change will occur when the car reaches a velocity of 5 miles per hour, the second change at 8.17 miles and the third at 14 miles per hour.

With the arithmetical progression the first change could be made at 6.5 miles per hour, the second change at 10.3 miles and the third at 14 miles per hour.

This comparison shows clearly that a driver could get into third speed quicker with the geometrical progression than with the arithmetical. The accelerating power of the car would also be greater and the speeds at which the changes could be made would be more quickly reached because of the greater power of the motor at higher speeds. The motor speeds at the times of throwing out the clutch to make the gear changes in the geometrical case would be 673, 666 and 684, while in the arithmetical the speeds would be 870, 625 and 543.

A Car Comparison

Let us examine the performance of the two types of gear set under road conditions. In order to present this in a form readily understood at a glance, it will be necessary to start

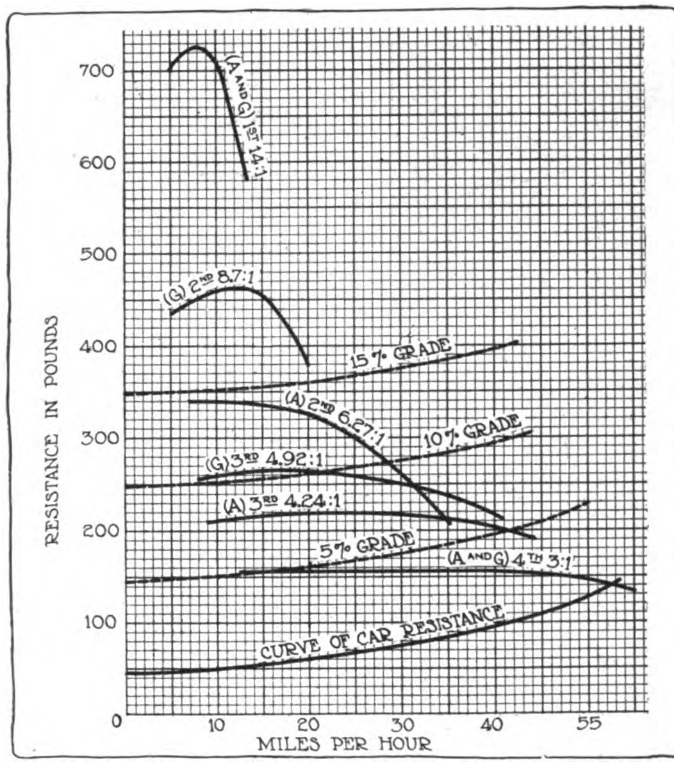

Fig. 7—This diagram is for the purpose of comparing the power at the clutch of the car obtained with arithmetical and geometrical ratios gearbox and the actual resistance of the car and, further, to show the superiority of the geometrical over the arithmetical type of gearbox. It also shows the speeds at which a car could ascend different road grades with the two types of gearbox and, further, shows the maximum grade that can be ascended with these two kinds of gearboxes for each gear ratio. For example: On third speed the car with the arithmetical gearbox can just ascend a 5 per cent. grade at 41.5 miles per hour, but could not ascend a 10 per cent. grade, whereas this car fitted with a geometrical gearbox would ascend the 5 per cent. grade at 41 miles per hour and the 10 per cent. grade at 20 miles per hour. Further, the car using the arithmetical gearbox and in second speed could not ascend a 15 per cent. grade, whereas with a geometrical type of gearbox it could ascend a 20 per cent. or steeper grade at 15 miles per hour. In low and direct drive, there is not any difference between an arithmetical and a geometrical gearbox, the difference lies only when using second and third speeds in a four-speed box

with the torque curve of the motor. Fig. 6 shows the actual horsepower curve of a 4 1-8 by 5 1-4-inch motor. The gear ratios of the arithmetical ratio box were 14, 6.33, 4.04 and 3. Using these with 35-inch diameter wheels gives the revolutions per minute of motor for car speeds from 5 to 35 miles per hour when running with the different speed reductions.

4—State the course taken, cars run, and order in which cars finished, in the New York to Paris race several years ago in which the Thomas Flyer was the only American car entered.

FORD P. DECKER.

Elmira, N. Y.
R. F. D. No. 2, Box 34.

—1—The reasons for the use of the semi-floating axle and the construction of the type used in the Pierce-Arrow cars are best explained in the words of David Fergusson, chief engineer of this company.

Floating Axle on Trucks

"We use a semi-floating axle on our pleasure cars. On our trucks we use the full floating type. We have designed and made floating axles for experimental pleasure cars, the same in every other respect as the semi-floating and found them to be much more complicated and to weigh very considerably more than the semi-floating type. The weight of the axle is of utmost importance, this being unsprung weight and the effect of this on pneumatic tires is very destructive. The extra weight on the solid tires of a truck is of small consequence. We will therefore discuss this construction entirely in regard to pleasure cars.

"The semi-floating axle gives two less loose joints (the hubs being securely fixed to the ends of the live axle) to cause rattle and clatter. It gives very much steadier and truer running rear wheels and therefore a more stable car, this due to the axle bearings being so far apart. This construction is very much lighter, giving longer tire life. It is altogether more simple there being far fewer parts and what is more, it is no experiment, as it has been successfully used by some of the highest grade manufacturers for many years and is employed in the heaviest and most powerful cars in the world, which have an enviable record for long mileage and freedom from trouble.

Only Takes Torsional Strains

"The theory of the full floating axle is to utilize the live axle for torsional strains only and the axle case tube for the dead load of the car only. To fulfill this condition each car wheel should be mounted on two ball or roller bearings on the tubular extension of the case, making adequate provision for taking care of end thrust and the live axle must be slightly free in both the compensating gearcase and the hub of the car wheel. There is a tendency to make the wheel bearings on the small side in order, to keep down the diameter and length of the hub; this gives very poor support to the wheel and it is liable to wabble on the axle case extension and severely overload the bearings.

"In order to make the wheel more stable some designers secure the outer ends of the live axle direct to the hub of the wheel. This is very bad practice where the standard two bearing hub is used, as it is very difficult to line up the live axle sufficiently accurate, when secured to the hub without tendency to bind the bearings in the hub, also any deflection

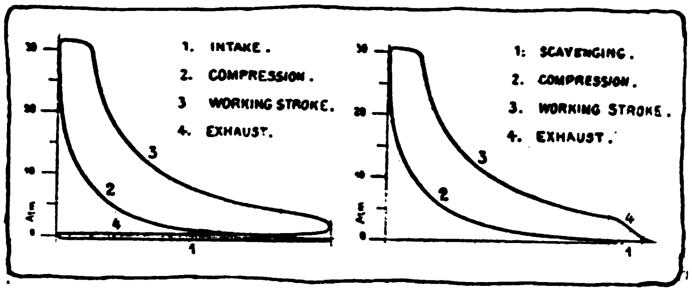

Fig. 2—Diesel engine cards, left four cycle, right two cycle

of the axle case causes a bending moment in the live axle and an excessive binding in the bearings in the wheel hubs, in fact these bearings may be frightfully overloaded in this manner. This construction really defeats the object of the full floating type which is to relieve the live axle of everything but torsional strains.

Diameter Should Be Larger

"In none of the above arrangements is provision made for resisting the bending moment that is imposed upon the live axle towards the outer ends when the wheel strikes the curb or is running in a rut with the car swaying from side to side. The diameter of the live axle at the hub should be at least from .25 to .375 inch larger in diameter than the diameter of the small end of the live axle when this is designed to resist torsion alone. Of course, this could readily be done, but designers appear to be more interested in keeping down the diameter of the bearing and thereby making a neater and lighter hub.

"The above constructions are all supposed to be developments of the semi-floating axle. In many cases they are not nearly as good.

"There are many points in favor of the older design when it is modified as shown in Fig. 4. Here the center line of the rear wheel is brought as close to the center of the outer axle bearing as possible, the diameter of the live rear axle is made very large at the outer ends in order to securely attach the hub and to adequately take care of the bending moment imposed upon it, not only by the overhang from the bearing but due to the rear wheel striking the curb or running in ruts with the car swaying.

"The inner end of the live axle is made smaller in diameter as this end has little more to do than take the torque of the engine. This live axle is made of the very finest chrome nickel steel, heat treated to give an elastic limit of not less than 110,000 lbs. per sq. inch with a reduction of area of not less than 55 per cent.; it is therefore well calculated to withstand any torque and bending moment that may be imposed upon it. The diameter of the live axle at the outer bearing is more than sufficient to admit of using a bearing abundantly capable of taking both the radial and thrust loads. This construction admits of a very short and stiff axle case tube.

Alignment Permanent

"It allows of a very small and light hub which may be quickly withdrawn by means of a wheel puller provided in the tool kit. The case securing the outer bearing can then be unscrewed and the live axle withdrawn without dismantling the rear axle housing. A slight yielding of the rear axle casing does not materially affect the alignment of the outer bearing. In good cars the live rear axle is generally made of high grade alloy steel. Very little extra weight is required to make this axle .25 to .375 inch larger at the outer end and this amount admits of this live axle taking care of both bending moment and dead load, in addition to the torque, much more effectually than can the tubular part of the rear axle case, which is seldom made of a material of greater strength than 70,000 pounds per square inch elastic limit and which is usually swaged down to a much reduced diameter to admit of using reasonable sized bearings, in the case of the full floating design.

"From the above it will be seen that the last described construction is really the most logical to adopt, as although some floating types give similar advantage, yet they will probably weigh more if they are properly designed. The outer ends of these live axles when secured to the rear wheel hubs must be made as previously mentioned, from .25 to .375 inch larger in diameter to adequately take care of the great bending moment occurring when the rear wheels are running in ruts and the car swaying. This would necessitate a much larger diameter bearing than indicated in these illustrations and it is only reasonable to infer that the load imposed upon the outer ends of these live axles is far greater than the combined torque and vehicle load, that if the axles were capable of taking this strain, they are certainly capable of carrying the weight of the vehicle which will really impose no additional load on these live axles than what they already must be capable of carrying. Why not, therefore, utilize these already enlarged live axles on which to apply the bearings that carrry the weight of the vehicle?"

Diesel Engine Principles

2—The Diesel motor is operated either on the four-stroke or two-stroke principle and the operations of the motor in each of these cycles are shown respectively in Figs. 3 and 5.

The primary differences between the Diesel engine and the ordinary type of gasoline engine is in the injection of the fuel under pressure and the firing of the charge by the heat of high compression. Starting with the engine on the firing stroke, the charge is fired by the high compression heat. The compression in the Diesel engine is 500 pounds to the square inch. As the piston is forced downward some of the energy is absorbed in putting pressure into the fuel oil tank. This pressure is 800 pounds to the square inch, which is sufficient to overcome the compression pressure in the cylinder.

At the end of the firing stroke the exhaust occurs in the usual manner throughout the entire range of one stroke. On the next out stroke the engine draws in a charge of pure air

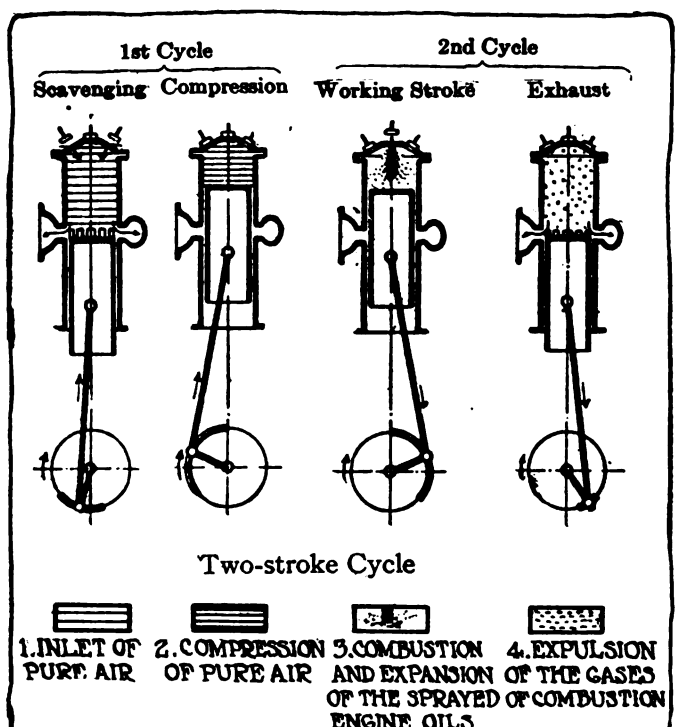

Fig. 3—Diagram showing the operation of the Diesel engine with a two-stroke cycle

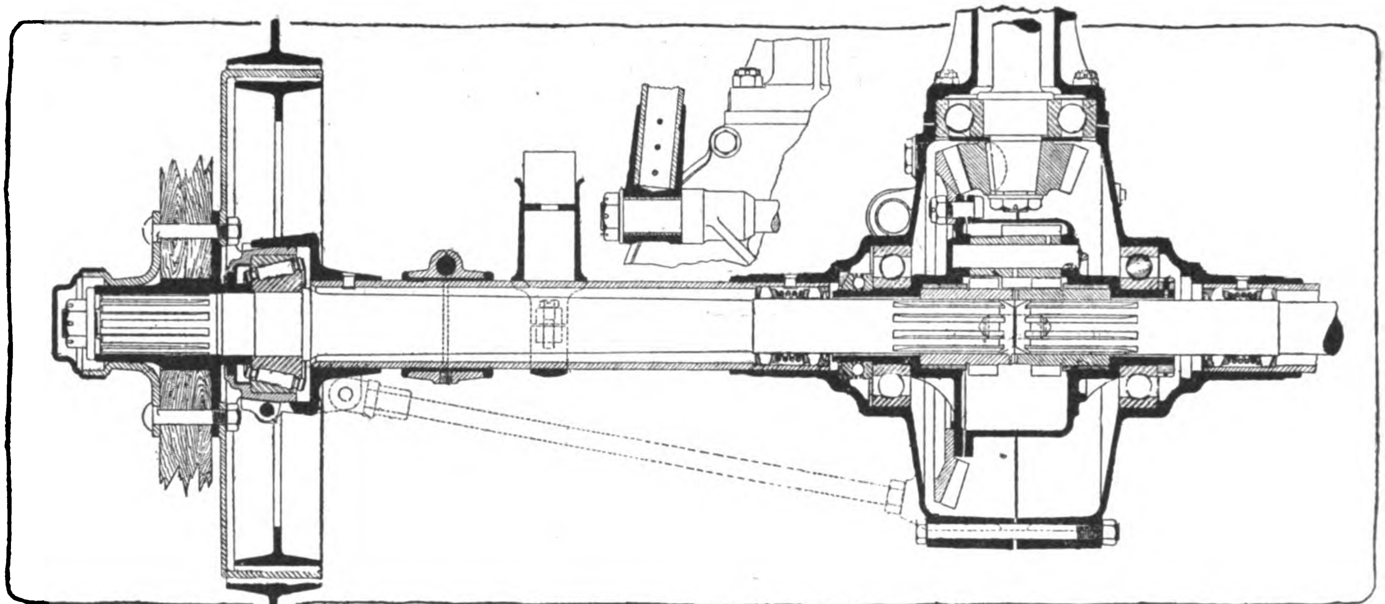

Fig. 4—Sectional view of the semi-floating axle design as incorporated in the Pierce-Arrow car

through the intake valve, which is opened at the conclusion of the exhaust stroke.

The next stroke is the compression stroke in which the pure air is compressed up to a pressure of 500 pounds to the square inch. When the piston has reached the top of the stroke the fuel valve opens and the charge is injected into the cylinder. The fuel forms a combustible mixture with the air in the cylinder and at the pressure in the cylinder begins immediately to burn. The burning in the Diesel engine must be distinguished from the explosion in the ordinary gasoline engine.

Two-Stroke Cycle

On the two-stroke cycle the strokes are divided into two parts, that is, two functions are performed at each stroke. referring to the diagram, Fig. 2, it will be seen that the first part of the up stroke is devoted to scavenging the motor. The second part of the stroke compresses the pure air. On the downstroke the first part is the working stroke and the second part is the exhaust.

The reason that Diesel engines are not used successfully in automobile work is because all the disadvantages of the type are most accentuated in the small units that would be necessary. In the first place, the high compression and the pressure under which the fuel must be forced into the cylinders gives rise to requirements in construction which would make the engines too cumbersome and unwieldy for a motor car. The difficulties also apply to the construction of the pistons, valves, fuel pumps, etc.

3—The average weights full equipped are as follows:

Pierce		Packard		Peerless	
Model	Weight	Model	Weight	Model	Weight
38	4400	38	4400	38	4400
48	5100	48	4700	48	4800
66	5400			60	5100

4—The course of the New York to Paris race was from New York City to Albany, Buffalo, Cleveland, Toledo, Chicago, Omaha, Cheyenne, Granger, Ogden, Reno, Carson City, Goldfield, Crucero, Daggett, Mojave, Saugus, Santa Barbara, San José, San Francisco, then across the Pacific by vessel to Kobe, Japan; Tsuruga, Vladivostok and by way of Harbin, Tschita, Irkutsk, Omsk, Tomsk, Tiumen, Ekaterinburg, Nijni-Novgorod, Moscow, St. Petersburg, Berlin and Paris. See Fig. 1.

This is a total distance of 21,000 miles, 13,000 miles on land and 8,000 on water as the crow flies. Many miles were spent, however, in detours made necessary by misdirection and unforeseen obstacles.

The contestants were as follows: De Dion, Moto-Bloc, Sizaire-Naudin, Zust, Protos and Thomas. The time and order of finish were as follows: Thomas, 42 days; Zust, 53 days; De Dion, 56 days. The Protos quit at Seattle, Moto-Bloc at Cedar Rapids, Ia.; Sizaire-Naudin at Red Hook. N. Y.

To Paint Brass Black Saving Polish

Editor THE AUTOMOBILE:—I have bought a new Ford car, and I would like to paint black the brass trimmings, such as the radiator, headlights and so on. I would be pleased if you could tell me what kind of paint to use that would do a nice job and stand the heat of the lamps and radiator.

Beaumont, Tex. A. T.

—The simplest method of preparing a black varnish for brass is to fuse 3 pounds of asphaltum, and after it has been melted add .5 pound of shellac and 1 gallon of oil of turpentine.

Does Not Favor Muffler Cutout

Editor THE AUTOMOBILE:—I note the assertion in The Rostrum that I did not read the article on the muffler cutout throughout, and in reply will say that I noted the "loop-hole" before writing you.

The tone of the whole article was in favor of the use of the muffler cutout and therefore my protest. How would it be possible to make a driver hear on the road, in case you wished to pass him, if he had his cutout open and the road was so narrow that you could not run alongside of him?

Rockville, Conn. ALLEN HAMMOND.

—The muffler cutout question has been argued pro and con for some time and there does not seem to be any better solution of it than that it should not be used where it interferes with the safety or comfort of others. In municipalities of any size they have recognized this fact and have barred the use of muffler cutouts.

There can be no doubt that with some drivers the noise of the exhaust of the engine is as music to their ears. This is particularly noticeable in the neighborhood of races. At the recent Indianapolis race hundreds of cars were parked in the infield of the Speedway, and fully eighty out of every hundred were operated with the cutout open. The drivers of these cars were victims of the psychological spell of the races and took a keen delight in the noise which was suggestive of speed.

In running along the average country road the muffler cutout can do no harm except in such a case as you mention, where the road is so narrow that a car coming up from behind wants to pass. But on the other hand, the man who drives with his cutout open is generally the kind of man who is driving so rapidly that you would hardly care to pass him on a road of that width.

New York Dealers' Licenses $15

Editor THE AUTOMOBILE:—In obtaining agency for a car, what is the first process in regarding license number, to whom and when do I make application for same, and the cost of same in New York State? What particular form of license do I apply for? A license number for dealers taken out in August or September expires when? Is there any rebate from the State license price when taken out late in season as above? As a rule does the dealer pay the freight charges on a car sold to owner from factory?

Auburn, N. Y. SUBSCRIBER.

—In applying for a dealer's license you should forward your application to the secretary of state at Buffalo, N. Y., who will give you an application blank to fill out. The cost of the license is $15 for the first pair of plates and $2 a pair for each extra set of license plates. The same pair of plates can be used on several cars for demonstrating purposes. The license expires the first of February following the issuance of the license. There is no rebate on dealers' licenses when they are taken out late in the season.

Dealer Does Not Pay Freight

The dealer does not as a rule pay the freight on cars which are purchased from him. He sells the cars f.o.b. the city in which they are manufactured. It is the general practice to secure one-third the purchase price on receipt of the order and the remaining two-thirds on delivery of the car.

How To Time a Ford

Editor THE AUTOMOBILE:—Would like to ask what is the correct timing on the Ford. Would it increase the power to file the valve stems so as to close the exhaust valve on top dead center?

San Diego, Cal. J. SCOTT.

—Set the camshaft so that the exhaust valve is just beginning to close when the piston is on top dead center. The intake valve should begin to open when the piston has moved down 1-16 inch from this position. Filing down the valve stem would decrease the power unless the stems are so long that the valves cannot seat at all.

Two Gears Shift at Once

Editor THE AUTOMOBILE:—1—Will you kindly tell me how I can repair my car? When I change from intermediate to low, or from high to low very quickly, the gears go in high and low both. The car stops with a jerk and I cannot change to neutral until I get underneath the car and kick out high. I have tried everything that I can think of, but it has no effect. As long as I change slowly it works all right. I shortened the rods, put more tension on the lock springs and moved the forks, but it made no difference.

2—Is there any way of adjusting the spring tension on the clutch of this car?

3—How can I replace the felt grease retaining washers in the six and also in the model S-20 1912 Studebaker?

4—What effect have moth balls on gasoline? I have some friends who put moth balls in their gasoline, and they say they get more power from their engines.

Sterling City, Cal. ELMER MARION.

—1—Either the shifting rods are not the right length or the springs that bring them back to neutral are weak. Replace these springs, and if this does not remedy the difficulty try adjusting the lengths of the rods.

2—The tension of the clutch spring can be adjusted by screwing up on the nut that holds the thrust bearing in place. It is possible that this will not make the clutch hold. If it does not, then the clutch leather should be replaced. To do this it will be necessary to remove the clutch cone. Take the universal apart and then unscrew the bolt that holds the thrust bearing in place. After this the clutch spider can be removed.

3—You do not state where these washers are, although you probably mean the washers in the wheel hubs. These may be replaced after the wheels are removed.

4—The use of moth balls will increase the power slightly, but they have a corrosive action and tend to carbonize the motor.

Where To Obtain Spark Gaps

Editor THE AUTOMOBILE:—I would like to know where I can buy auxiliary gaps to be placed in the high-tension cables. Ones that can be opened and closed at will, so that one can determine whether the plugs are sparking or not.

Cleveland, O. O. P. WARNER.

—Spark gaps, such as you describe can be obtained from any of the following concerns, according to the Automobile Trade Directory:

Bremer & Mooney Mfg. Co., 538 Muskego street, Milwaukee, Wis.

Champion Spark Plug Co., 134 Upton avenue, Toledo, O.

Cut-Out Switch Co., Broadway and 195th street, New York City.

Dalitz Mfg. Co., 3134 Payne avenue, Cleveland, O.

Hemmeter Spark Gap Mfg. Co., Dime Bank Bldg., Detroit, Mich.

Herz & Co., New York City.

George W. Manville, Bridge street, Towanda, Pa.

Lee C. Mapes, 16 Fulton avenue, Rochester, N. Y.

Eugene D. Means, Towanda, Pa.

A. R. Mosler & Co., Mt. Vernon, N. Y.

H. M. Sheer Co., Quincy, Ill.

Smith & Gunn, 22 E. Broad street, Burlington, N. J.

Toledo Auto Devices Co., Gardner Bldg., Toledo, O.

These gaps tell exactly what is happening at the plug and by their use many ignition troubles can be traced.

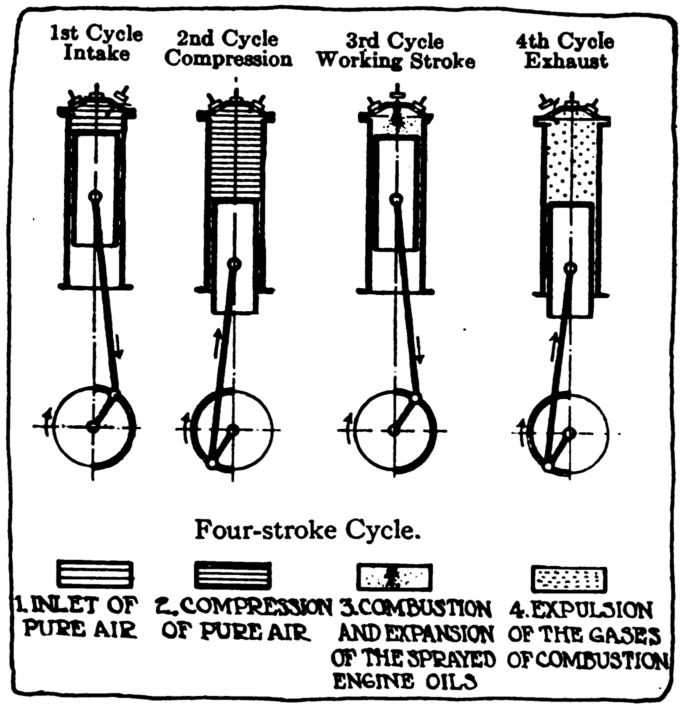

Fig. 5—Diagrammatic illustration of the principle of the four-stroke cycle Diesel

The Engineering Digest

Synthetic Rubber Unsettles the Market But Technical Facts Fail to Support Faith in Its Quality

—

RAPID OXIDATION THE BANE OF ARTIFICIAL GUMS

ONE thousand tons per week is the amount of Pavea Synthetic Rubber which, it is stated, will be turned out regularly before the end of this year at large works near Manchester, England, by a one-million dollar corporation. It is also stated that the cost of production for this substance will not exceed 8 cents the pound and that it will be marketed at 10 cents below the current quotations for first Para latex, whatever these may be at any given time in the future. Samples of the product have been distributed among rubber buyers and, according to the London correspondent of *The India Rubber World*, there is no doubt that the apparent quality of these samples has had the effect of depressing the price of plantation rubber at least 2 cents per pound; nor that the raw rubber merchants will delay their purchases this year and await the developments of the Pavea concern. Various vegetables and wild plants are mentioned as the source of the new rubber, and all the officials of the manufacturing company have been sworn to secrecy with regard to the nature of the raw material and that of the production process. The inventor is a Mr. Russell.

Commenting editorially upon these reports *The India Rubber World* in its issue of July considers that Para and Singapore would do well to maintain their dock facilities for yet a little while, as good samples of synthetic rubber have been distributed before without any consequent disturbance of the rubber market. "And then, as noticed last month," it adds, "this new rubber has a very considerable constituent of resin, which gives rise to the conjecture that it is somewhat more akin to natural rubber than to the products of synthesis."

The promised production of one thousand tons per week calls for a vast amount of raw material to be handled, and a material which must be of exceeding cheapness to realize a final production cost anywhere near 8 cents per pound. These things, all considered, narrow the surmises down to a choice between a great fundamental discovery and an industrial hoax. If the reports are accepted at somewhere near their face value, a discovery of some importance must have been made, but even in that case the question remains whether the technical properties of the product have been fully ascertained. With the application to automobile tires in view it is important whether the product shares in the peculiar shortcoming which has so far characterized all synthetic rubbers, though it escapes observation that does not extend over some length of time. This is the tendency to relatively rapid oxidation and hardening.

What German Investigators Found

In this respect a lecture delivered January 23 this year by Dr. A. Holt before the Heidelberger Chemical Society illuminates the probabilities by showing facts in connection with the properties of other synthetic rubbers which it proved most difficult to discover. With elimination of the most severely technical features, the lecture, which was supported by the showing of a large number of rubber preparations, conveyed in substance the following general information:

The difficulties of the subject are illustrated through the fact that we still know very little about the structure of guttapercha, except that its properties are very different from those of rubber while its chemical composition seems to be identically the same.

With regard to the hydrocarbon base of rubber we know with certainty only that 2 molecules of isoprene are changed into 1.5-dimethylic molecules of octo-cyclic formation. Starting from this bit of knowledge, Fritz Hoffman and after him many others succeeded in producing rubber from isoprene. The raw material for isoprene was turpentine but had to be abandoned as too costly and relatively scarce, although it was finally made to yield 65 per cent. of isoprene. Elberfelder Farbenfabriken then got isoprene from acetone. Badische Anilin und Soda-Fabrik made it from hydrated benzols or phenols. Neither quantity nor quality was satisfactory by these methods.

Where Standard Oil Products Come In

A great improvement was realized when the Badische, in working with fusel oil, devised a method for chlorating trimethylethylenes in vacuum and another kindred process. This gave a pure isoprene, but fusel oil was too scarce. Petroleum was taken up instead. It was eventually found practicable to transform by the chlorating method all the important constituents in petroleum—not only the isopentane—into pure isoprene, by way of trimethylethylene. This seemed to solve the question of raw material, as the United States alone can furnish 300,000 tons of pentane per year.

To polymerize isoprene into rubber proved a more stubborn task. Hoffman's original method was to heat the isoprene for a considerable time. Matthews, Strange and Harries discovered almost simultaneously the polymerizing effect of the alkali metals, such as sodium. But after all the hydrocarbon base of natural rubber could not be reproduced from the sodium-isoprene rubber and there was in the latter a corresponding lack of elasticity and an irregular resistance to vulcanization.

The Badische found two methods which led back to the natural rubber base. One consisted in the treatment of isoprene with the ozonides of terpene. The ozonide rubber obtained was tougher and more elastic than that obtained by heating, and, in contrast with the latter, did not dissolve in benzol but only formed a colloid. The second method consisted in using an alkali metal, especially sodium, in the presence of carbonic acid. The reactions were totally different from those obtained with sodium without carbonic acid. The product has a normal hydrocarbon rubber base and can neither be dissolved nor emulged in benzol, while made without the carbonic acid it has an abnormal base and is easily solvable. The carbonic acid rubber is similar to the natural Kondakow rubber.

Lack of Complete Identity Finally Shown Chemically

These three varieties of synthetic rubber—the heat-rubber, ozonide rubber and carbonic acid rubber—have different appearance and physical properties and also act differently with the usual rubber solvents. All of them have a tendency to oxidation, while natural rubber is much more indifferent to the oxygen of the atmosphere. Chemically they show great similarity. Harries had shown that, by an ozonizing process, levulinaldehyde and levulinic acid can be obtained from heat-rubber as well as from natural rubber. It was now demonstrated that these substances also could be obtained by cracking the ozonide and the carbonic acid rubbers, but in the case of the latter abundant quantities of acetonylacetone and succinic acid were produced at the same time. This led to the discovery that in all of them there was not only the 1.5-dimethylic hydrocarbon base of the natural rubber but also a 1.6 dimethylic base, from which alone the acetonylacetone and succinic acid could have been derived. By further experiments it was found, to the surprise of the investigators, that these substances also could be obtained from heat-rubber and from ozonide rubber, and in all cases in about the proportion of 8 to 2, which corresponds to the proportions of the two bases. On the other hand, it was found impossible to find even a trace of the 1.6-dimethylic base in natural rubber.

Complete identity with natural rubber does not therefore exist in any of the synthetic rubbers mentioned, and this accounts also for their shortcomings in physical properties. They are about equal in value to medium good natural rubbers and could be produced cheaply in any desired quantity if the steadily increasing production and steadily falling prices of natural rubber did not rise as an obstacle to the financing of their manufacture. Dr. Holt also thought that the infinitely large supplies of rubber which can be obtained from nature by cultivation would continue indefinitely to interfere with artificial production.—From *Kunststoffe*, March 1.

Lamplugh's Differential with Worm Drive and Silent Gear Reduction

MANY designers seek the ideal differential which will act as the standard differential does where the road friction is secure at both wheels but will lock itself wherever there is a tendency for one wheel to slip or spin around in the air. In some instances the proposed special designs are combined with gear-reduction devices in order to obtain a desired transmission ratio with a bevel-gear driving-mechanism of moderate dimensions. This is the case with the Renault differential for trucks and with that used on one of the Mercedes truck models. In both of these, which have been described in these columns, it may also be an object to divide the ordinary driving-stresses between two bevel-gear wheels, so as to be enabled to use smaller dimensions and gear teeth. In other cases the purpose is only to obviate the undesirable action of the ordinary differential which arises when road friction at the wheel rims does not check its freedom of movement, and the method adopted is to supply this check by other means. The Romeiser differential brake tried in the German army and described in THE AUTOMOBILE of June 11 belongs to this class as well as the Eden hydraulic check described in THE AUTOMOBILE of June 25. Romeiser's device produces only a constant friction which acts to equalize in some measure any unequal resistance to movement of the two driven vehicle wheels, while Eden aims to make excessive differential action check itself.

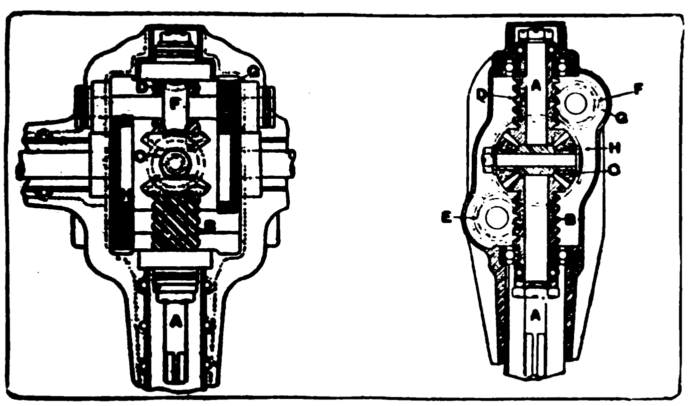

Fig. 1—Lamplugh differential with worm drive

F. Lamplugh of England now proposes a device in connection with worm drive which in other respects resembles that used in Mercedes "colonial" trucks. The claim is made that its use has been proved to increase the life of tires 100 per cent. and to reduce the fuel consumption 20 per cent., these results being obtained through the neutralizing of end-thrust in the worm drive and reduced slippage of the wheels. The construction is shown in Fig. 1 and may give a clue to the basis for these claims.

The drive shaft A extends through the rear-axle gear-casing, and a double stub shaft C is secured to it transversely, carrying the two driving pinions of the bevel-gear differential. In front of the transverse pin there is journaled upon A the left-threaded worm B integral with one of the driven pinions of the differential and behind it similarly the right-threaded worm D with the other driven pinion. B meshes with wormwheel E below it and D with wormwheel F above it. Upon one end of the shaft for wormwheel F there is mounted the plain spur pinion G which meshes with a spurwheel secured upon the inner end of the drive shaft for the left side vehicle wheel, and similarly a pinion H on the end of the shaft of E drives a spurwheel secured upon the right side wheel shaft.—From *Automobil-Welt*, July 3.

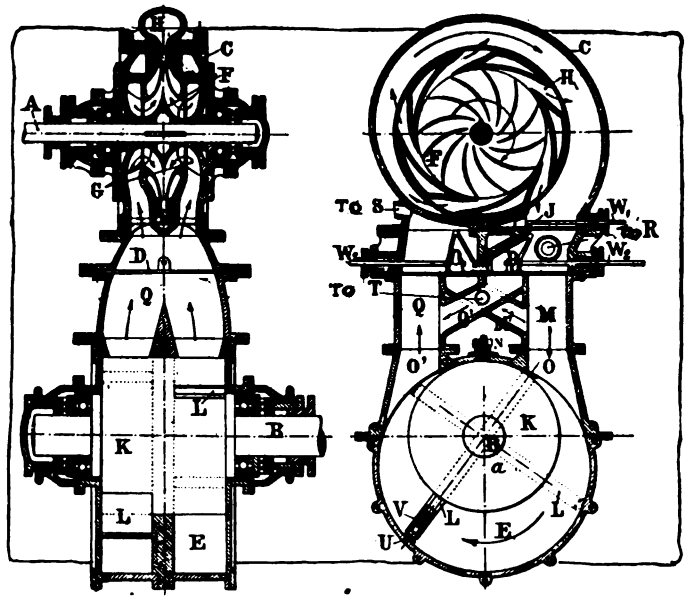

Fig. 2—Tourreil's hydraulic transmission "liquid belting"

Tourreil's Hydraulic Reducing Gear or "Liquid Belting"

THOUGH intended especially for reducing the speed of the propeller shaft in boats equipped with steam turbine engines the hydraulic reducing gear invented by Maurice Tourreil of France commands an interest outside of marine engineering circles for being a transmission mechanism by which the power of the engine is taken to the driven member in a manner not absolutely positive but susceptible of yielding when the resistance met is greater than that which can be overcome, in the same manner as in fire engines with centrifugal pumps where the accidental freezing of a hose nozzle or other clogging of the water channel causes neither the bursting of the hose nor the stopping of the engine. Drives of this character are by some authorities in the automobile technical world—Dr. Riedler of Berlin, for example—considered desirable for automobile trucks but have not so far been made practicable on the small scale required for this purpose. The hydraulic drives in actual operation all have the positive action of pumps with reciprocating pistons.

Tourreil calls his construction the *Courroie Liquide* or "liquid belting" and is able by means of it to make a propeller shaft revolve at a speed of 100 revolutions per minute when the steam turbine is operating at 2,500 revolutions per minute. The Melville gear installed in the American collier Neptune reduces 1,250 revolutions to 135, handling 6,700 horsepowers, and the Föttinger transformer, which is hydraulic in principle, has transmitted 9,000 horsepowers, reducing the speed from 850 to 135 revolutions with an efficiency of 90 per cent. for forward and 80 per cent. for reverse driving.

The construction of the "liquid belting" is shown in Fig. 2. The centrifugal pump C is actuated directly from the turbine shaft A and delivers the power through a rotary motor of a well-known type with paddle blades K, this motor being keyed upon the shaft B of the screw propeller. The conduit M establishes the connection from the pump discharge to the admission gate O of the motor, and the conduit Q completes the circuit by connecting the discharge gate O′ of the motor with the admission channel of the pump. The centrifugal pump comprises a wheel with two sets of vanes F with opposite pitch, so that the end-thrusts neutralize each other, two distributers G and a diffuser H, formed with partitions.

The rotary motor comprises the cylindrical body K in which two blades L can slide in and out at right angles with each other but each in its own plane. The space E, instead of having the circular form shown in the illustration, is elliptic and the shaft of K is placed in the minor axis of the ellipse so as to reduce to a minimum the variations in the length of the active portions of the blades. The jointed contact-shoes U in the ends of the blades are pushed outward by springs V to secure tightness and a similar contact-shoe N separates the admission channel from the discharge. By displacing the connected vanes D by means of rods W_2 the conduits M and Q are blocked and the oblique conduits M′ and Q_1 are opened. This reverses the direction of movement of the liquid and consequently of the transmission. To vary the speed of the motor member of the mechanism the throttle vane J is operated by means of rod W_1, so as to reduce the delivery from the pump member, the speed of the motor being reduced in the same proportion. A safety valve T establishes a connection directly from M to Q when a sudden reversal of the mechanism causes pressures too high for the organs of the motor. Two air reservoirs R and S, not shown in the drawings, are connected with channels M and Q and serve to regulate pressures, forming at the same time fluid reserves to compensate for losses by leakage. Heating of the mechanism is obviated by having a portion of the fluid bypassed through a cold-water cooler.

The efficiency of this transmission, when it is made in such large dimensions that the maximum pressure on the fluid does not exceed 10 kilograms per square centimeter, is said to be 90 per cent. for the rotary motor, 90 per cent. for the centrifugal pump—which under these working conditions does not need to have more than one wheel—and 96 per cent. for the conduits, giving a total efficiency not below 75 per cent., which however is lower than that of the Föttinger construction.—From *Le Génie Civil*, June 27.

Germany's Elaborate Statistics

(*Continued from page* 173)

In the district of Berlin, out of every 100 motor cars 45.1 were implicated in some destructive traffic incident during the year and out of every 100 motor wagons 20.9 were so implicated, but these proportions are much reduced in the country as a whole, being due largely to the great number of taxicabs in the metropolitan districts. Taxicabs show in fact the greatest liability to accidents of all motor vehicles, motor omnibuses excepted. Out of 100 taxicabs 66.4 were in accidents at one time or another during the year, and out of 100 motor omnibuses 79.2. This unfavorable showing for the public vehicles is ascribed less to any lack of skill of the drivers than to the fact that these vehicles operate in the closest population and as many hours every day as they can be kept going.

The 22,457 motorcycles of the empire were engaged in only 243 destructive traffic incidents and the 100 motorcycle carts only in 4. This leaves, out of 10,257 accidents standing on record against motor cars and motorcycles combined, 10,014 against motor cars alone. The number of motor cars being 60,876, it follows that out of every 100 motor cars 16.4 participated in destructive accidents. Similar reasoning shows that 17 per cent. of the motor wagons were in accidents, since a total of 9,639 motor wagons were in 1,636 accidents. The possibility that some of the vehicles may have been in accidents repeatedly and may thus have made the score worse for the average is unconsidered.

[An error in the statistical method may here be noted, which consists in figuring the liability to accident on the basis of the accidents which took place from October 1912 to October 1913 and at the same time on the basis of the number of vehicles recorded for January 1, 1914. Considering that the increase in motor cars during 1913 was 22.3 per cent., the recorded numbers relating to accidents should properly be figured against a correspondingly reduced number of cars; which would make the showing worse.—ED.]

A further analysis of the figures brings out that the liability to accident is influenced by the power of the vehicles but also that great improvement in the avoiding of accidents has been brought about since 1907. The figures bearing on this side of the subject are given in the appended table, which shows that among motor cars those ranging in power from 16 to 40 rated horsepowers are now more dangerous than either those with lower or those with higher power, though the latter formerly were recorded in a proportionately larger number of accidents. The slight discrepancy between the percentage of 17.8 given for motor cars in general in this table and that of 16.4 as figured above is not accounted for.

The Legal Responsibility

The owners of the motor vehicles engaged in accidents were reached in 12,464 out of the 12,772 cases. The drivers were detained without difficulty in 11,974 cases, while 190 tried to escape and 608 succeeded in escaping by flight. Out of these 608 who fled 356 were afterwards arrested. The percentage of drivers who escaped after an accident has fallen from 9.8 in 1911 to 5.3 in 1912 and again to 4.8 in 1913. Singling out the motorcycles, it is found that while their accidents are few 10 per cent. of the drivers flee from an accident when it occurs.

On account of the accidents police fines were imposed in 1,245 instances, but in 259 of these cases it was the drivers of other vehicles or outsiders who were fined.

Criminal prosecution was ordered in 3,976 cases, and 2,797 of the actions were taken against drivers of the motor vehicles, 251 against third persons and 28 against "John Doe."—From text and tables in *Automobil-Rundschau*, June 30.

Gearset of Geometrical Design Is Best—Part II

(*Continued from page* 175)

By means of these revolutions per minute and the horsepower curve, the power at the clutch is worked out for each case and gives the car resistance to movement in pounds.

Where Geometrical Gearset Is Better

The curves thus obtained are plotted in Fig. 7 and marked A. The resistance curve of the car is drawn and then several other curves parallel to it representing the total car resistance when ascending grades having a slope from 5 to 15 per cent.

These curves show us that the car cannot ascend a 15 per cent. grade except on low gear. It could not ascend a 10 per cent. grade in second speed faster than 32 miles per hour. A 5 per cent. grade would probably necessitate changing the gear from fourth speed to third in order to ascend comfortably. The curves marked G show the traction resistance overcome when geometrical progression is used in the gearbox. This car could easily mount a 15 per cent. grade on second speed at 20 miles per hour, whereas the arithmetical gearbox would only permit this on first speed and that at 12 miles per hour only.

The high or fourth speed must be changed to third at a 4 per cent. grade but after changing, the range of G is greater than A which means a change again for A sooner than for G, the difference being about equal to a 2.5 per cent. grade in favor of G. This would be of advantage to G when touring through country where the grades as a rule did not exceed 8 per cent.

The usefulness of third speed gears on G would be greatly extended over that of A, as the maximum speed of A on second would only be 20 to 30 miles compared to 30 and 40 miles for G.

As an example of road practice let us take an imaginary road, the cars starting from rest along a level stretch.

A starts on first and goes on through second and third into high.

During this change his motor runs up to a 1,000, drops to 445, runs up to 1,000, drops to 616, speeds up to 1,000 and drops to 741, the car then running at 25.8 miles per hour.

A grade of 4 per cent. is reached followed by an 8 per cent. grade. Gear is changed to third and the motor speed rises to 1,000. At 8 per cent. grade the gear is changed to second, the motor speed increasing to 1,500 but car speed remaining at 25 miles per hour. Level is reached and speed changed to third, motor revolutions per minute dropping to 1,000.

Then the driver changes to fourth speed, the motor speed having decreased to 720 and then increased to 1,000 with car travelling 35 miles per hour. Now let us try G on the same stretch of road. He starts on first going through into high with the motor speed dropping from 1,000 to 600 at each gear shift. The last shift is made at 14 miles per hour which shows that less time has elapsed for the gear shifts than for A.

Following Motor Speed

On reaching the 4 per cent. grade, gear is shifted to third speed, the motor speed rising to 1,650. At the 8 per cent. grade the car is running 35 miles per hour without the necessity of dropping into second speed as the motor is turned 1,410 revolutions per minute. On reaching the level, gear is changed to fourth speed and the motor drops its speed to 1,000 revolutions per minute. In the case cited above G has made two less gear shifts than A but the motor has run at higher speed as well as the car.

For purposes of comparison the gear ratio charts of several foreign cars are plotted in Figs. 8-11. These were taken from the details of the cars published in the *Automobile Engineer Year Book.*

87% of Drivers Careless at Crossings

NEW YORK CITY, July 17—Railroad officials throughout the country note that accidents to automobiles on grade crossings appear to be increasing at an alarming rate. An official of one of the principal roads in the country is authority for the statement that fifteen out of every hundred persons killed or injured in grade crossing accidents are occupants of automobiles. On this basis there were approximately 300 persons killed and 750 injured driving automobiles over grade crossings in the two years ending June 30, 1912, and, while complete figures for the succeeding years are not available, the frequency with which such accidents occur would indicate there has been no diminution but rather an increase in this class of accidents.

On three important crossings on a large eastern railway system a test was recently made to determine with what degree of care the average person approached and crossed the tracks. During a period of 8 hours 923 automobiles crossed the tracks. Of that number the drivers of 701 cars or 87 per cent. did not look in either direction along the tracks before crossing. There were 83 of them or 9 per cent. who looked in only one direction, while only 39 or 4 per cent. took the precaution to look both ways. The automobile accidents that occur on crossings are most lamentable, the victims usually being men or women of intelligence and good social standing. What makes it all the more distressing that these accidents should occur, is the fact that a little ordinary care and caution on the part of the drivers of cars would prevent them.

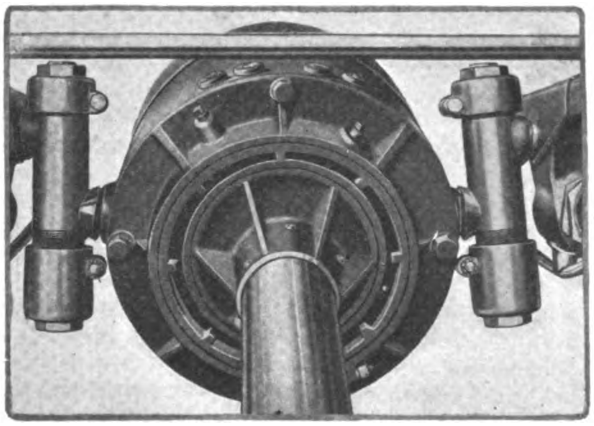
Only 2% of Drivers Careful at Crossings

EL PASO, TEXAS, July 18—The Safety First Department of the El Paso & Southwestern Railroad is collecting some interesting and valuable statistics on the probable cause of automobile accidents at railroad crossings. This department recently stationed a representative at the crossing of its track on Oregon street in this city for the purpose of keeping a record of the manner in which each motor car driver approached the crossing. During a given time this man was on duty, a total of 3,607 automobiles crossed the track and each driver was classified as to his regard for safety and carelessness. The figures show that 80 per cent. of the drivers in crossing the tracks, did not look in either direction; 17 per cent. looked in one direction and but 2 per cent. of the whole number looked in both directions before crossing. A total of 290 crossed the tracks at a speed greater than 20 miles an hour, without looking in either direction. Six saw a flagman posted at the tracks and crossed despite the warning. In a statement issued by the El Paso & Southwestern Railroad, it is shown that during the 2 years ending June 30, 1912, 300 motorists were killed and 750 injured by being struck at railroad crossings. No figures of a later period are available but it is said that the large increase in the number of automobiles would naturally lead to the conclusion that there was a considerable increase in the number of accidents. It is in order to educate the people along its line to have a better regard for the rules of safety in driving their cars that this campaign has been inaugurated by the Safety Department of the El Paso & Southwestern.

New Woods Electric Uses Worm Drive

New Spring Suspension—Motor Suspended on Ball Joints —42-Cell, 13-Plate Batteries Now Employed

THE Woods Motor Vehicle Co., Chicago, Ill., has entirely remodeled its line of electric cars for the 1915 season and incorporated a series of refinements. A new type of spring suspension is used, the drive is now by worm instead of bevel gears, the brakes are better, the motor supports stronger and the bodies more attractive and more comfortable. The result of this refinement is the production of a higher grade vehicle at a somewhat advanced price.



Motor suspension on the Woods electric showing the ball joint hangers upon which the motor is hung

The new Woods electrics are called: 1501, which has dual drive; 1503, with front drive; 1504, with rear drive; all of these being five-passenger broughams, while the two remaining cars are a four-passenger brougham with rear drive and a three-passenger roadster. The roadster is the only car of the line which uses bevel rear drive. All have lever steer.

One of the features of the construction is the spring suspension, in which an inverted U-shaped frame channel houses the springs. This calls for a departure from usual practice, in that the channel portion of the frame points downward. This is used for the front springs which are elliptic as well as the elliptic rear. In the front this saves almost 6 inches across, allowing the car to have a turning radius of 34 feet. In the rear it permits of using a wider body. The springs are merely set in the frame channel and two spring clips fastened around the frame.

Aside from the springing, a very important and effective construction is the means of propulsion. The rear springs are fastened to torque members instead of the rear axle housing, as used previously, and which construction is in use on most cars of today. The drive is taken through these torque members instead of the springs as it was before.

The motor is suspended upon ball joints, considered better than the brass-bushing method used on the 1914 models. The motor and supports rest upon a sub-frame attached to cross members and the sub-frame acts as a housing for one end of each torque member, as shown in an illustration herewith.

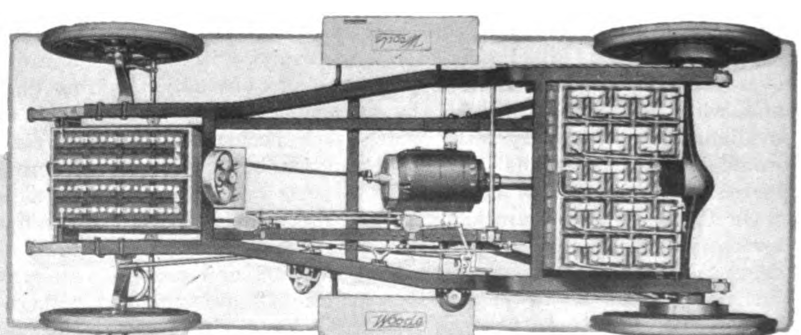
All Woods electrics, with the exception of the roadster, now are equipped with a worm-drive rear axle with the worm wheel on top and the driving worm on the bottom.

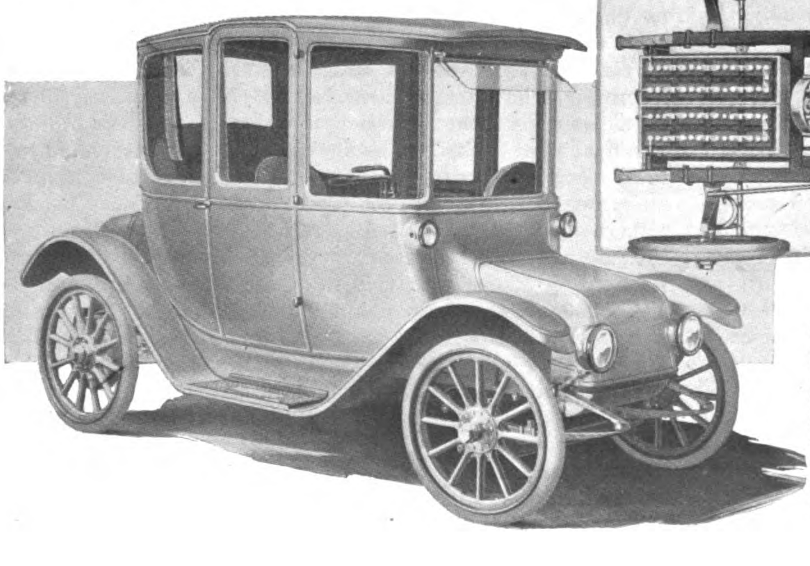
The brakes have been redesigned and the bands increased in size from 14 by 1 3-4 inches to 16 inches diameter by 2 inches wide. The cross-members of the frame are acetylene welded to the inverted U main frame. Rivets are used as an additional means of securing the parts.

The battery set is larger than used heretofore, the 1915 cars coming through with forty-two-cell, thirteen-plate batteries, while the previous models had forty-cell, eleven-plate accumulators. The batteries and the body are made in the shops at Chicago.

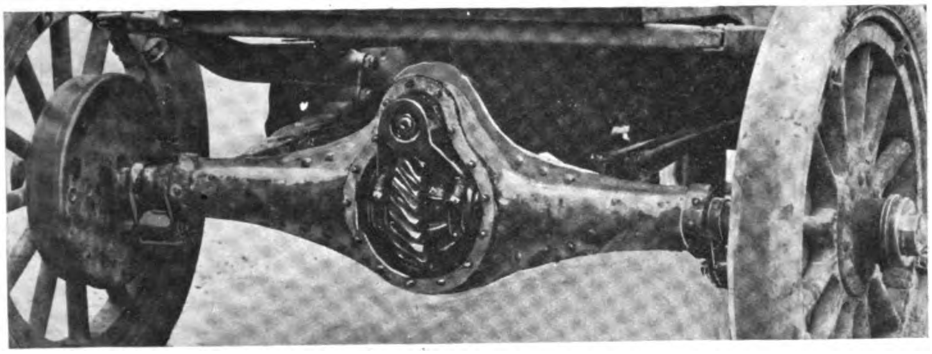
All cars have five forward and five reverse speeds, are equipped with 34 by 4-inch tires in front and 38 by 4 1-2-inch in the rear. The five-passenger broughams have a 110-inch wheelbase, the four-passenger 100-inch and the roadster 92-inch.

The new prices are as follows: Five-passenger brougham with dual control, $3,250; five-passenger brougham with either front or rear drive, $3,150; four-passenger rear drive brougham, $2,875, and the three-passenger roadster, $2,300.





Left—The 1915 Woods electric. Note the set-in front lamps, an exclusive feature. These lamps form an integral part of the front hood. Above—Plan view of the chassis used in the 1914 Woods electric, showing the position of the worm underneath the axle and the mounting of the rear springs on radius rods. Rear batteries are placed forward of rear axle. This illustration gives another view of the motor suspension shown in detail above. Note wideness of frame at rear, made possible by new spring suspension



Overhead worm drive axle used on Jeffery Chesterfield six for 1915. This replaces the bevel gear drive used on the 1914 Jeffery

Jeffery Six Has High-Speed Motor and Worm Drive

Block Motor Makes 2,500 R.P.M.—Cantilever Springs—Four-Speed Gearbox

JEFFERY has invaded the low-price six-cylinder field with its Chesterfield model selling at $1,650. This car is replete with features new to the Jeffery line. It has a 3 by 5-inch, L-head, block motor capable of running at 2,500 revolutions per minute; Daimler-type leather universal; four-speed gearbox; worm-drive rear axle; cantilever rear springs; Bijur starting and lighting system; 122-inch wheelbase and 33 by 4-inch tires. Fully equipped the car weighs but 2,850 pounds. In addition to the Chesterfield the two older Jeffery models, one a six and the other a four, are to be continued.

Equipment on the Chesterfield is unusually complete, the features of which are the combination speedometer light and trouble light on a spring wheel, fitted inside the cowl, English vanity case containing toilet articles, Collins quick-acting curtains, one-man top, headlight dimmer, and Folberth power tire pump. Roadster and five-passenger touring bodies of the full French streamline type are fitted.

2,500 R.P.M. by Chesterfield

The new Chesterfield engine has developed a crankshaft speed of 2,500 revolutions per minute according to the Jeffery engineers. The factory gives its horsepower rating at 35 to 42. On account of its late design and its great stroke-bore ratio, this is half again as much as the A. L. A. M. rating, which is 21.6.

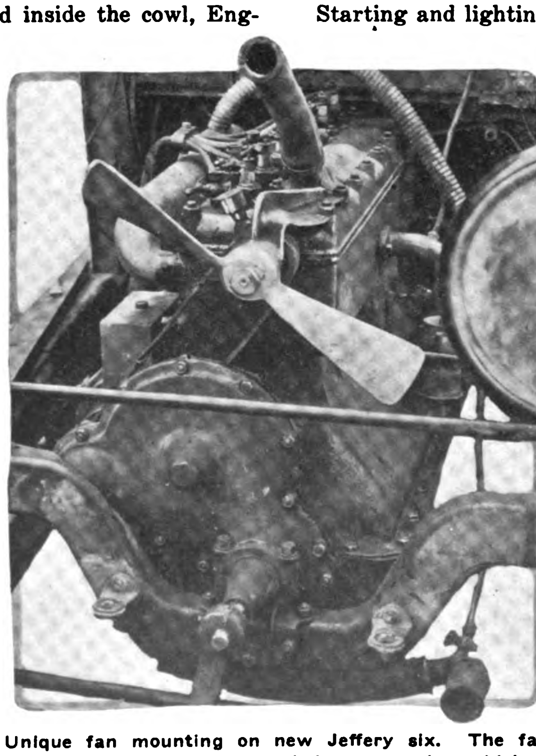
Light Reciprocating Parts

The engine presents a number of features worthy of notice. The entire upper portion of the crankcase and the block of six cylinders, is a single casting. The lower portion of the crankcase is an aluminum casting and a single removable plate opens up the cylinder heads. Particular attention has been given to the production of light reciprocating parts, and to secure an even balance of pistons and connecting-rods so that there may be no undue vibration to cut down engine speeds, and thus limit the power output. That efforts in this direction have met with success may be taken for granted from the statement of Jeffery engineers that the engine has been turned up to between 2,400 and 2,500 revolutions per minute without showing a drop in the power output. Naturally such speed cannot be obtained without larger valves than usual, and these are of Rich tungsten steel. Cooling is cared for by a pump circulating system with a honeycomb radiator through which the air is drawn by a two-bladed aviation type propeller fan. The mounting of this fan is unique in that the fan shaft and its pulley are carried on a bracket which is a single casting held by the cylinder head bolts at the front end of the engine. An eccentric bushing permits adjustment to take up whatever looseness develops in the belt which drives the fan from the magneto shaft.

Ignition is the Bosch independent system, and the Bosch equipment is carried throughout in spark plugs and cable.

Lubrication is by a constant level splash and gravity feed system in which there is a reservoir under the crankcase containing the oil supply. An open-end tube projects from the connecting-rod and leads to the connecting-rod bearing. At each revolution of the crankshaft this tube dips into the pan and the oil runs directly into the connecting-rod bearing. The cylinders receive their oil from the splash as in the ordinary splash system. There are only three gears in the timing system and these have helical teeth for quietness.

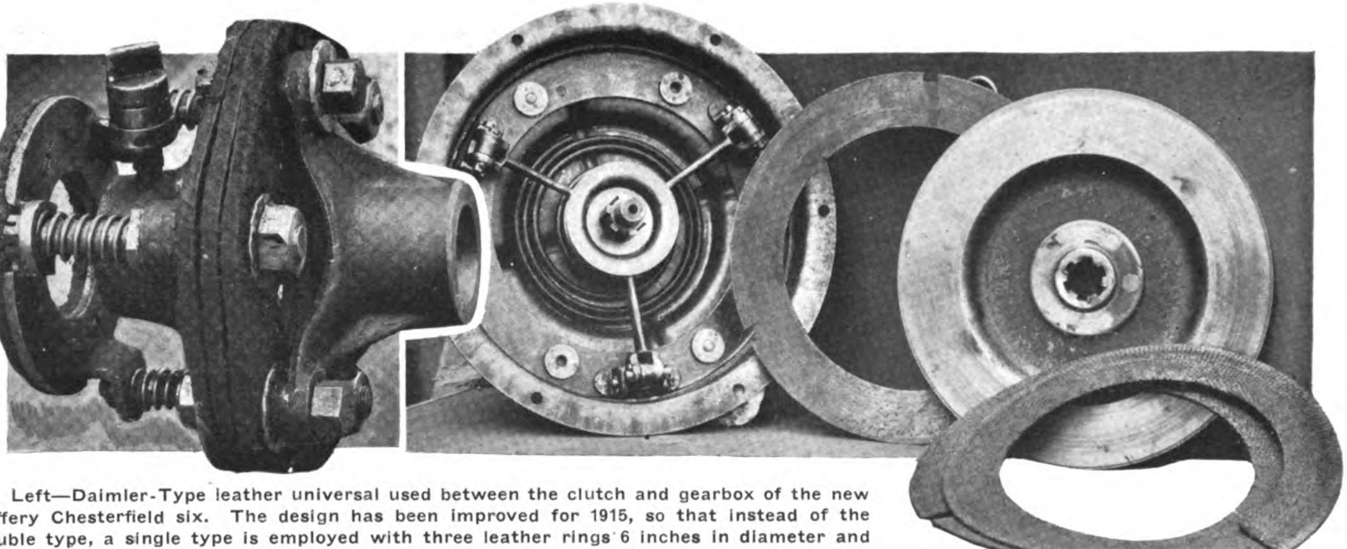
Starting and lighting is the Bijur system and consists of a generator and starting motor with control switch and Willard battery. The generator is mounted on the right side of the engine, and driven through the timing gears. When the engine attains a speed corresponding to between 7 and 8 miles per hour car speed, the regulating device contained in the rectangular box on the top of the generator begins to act, closing the circuit between the generator and battery, and maintaining a constant voltage at the generator regardless of speed or condition of the battery.



Unique fan mounting on new Jeffery six. The fan shaft and its pulley are carried on a bracket which is a single casting held by the cylinder head bolts at the front end of the motor. An eccentric bushing permits adjustment for looseness in the belt

Battery Is Well Protected

This constant voltage results in the battery receiving a charging current varying according to the condition of the battery, that is, when the battery is low the charging current will be high and when the battery is fully charged the charging current will be low, so that a low battery will be brought rapidly to a condition of full charge and thereafter will not be overcharged needlessly. The regulating device also performs the duties



Left—Daimler-Type leather universal used between the clutch and gearbox of the new Jeffery Chesterfield six. The design has been improved for 1915, so that instead of the double type, a single type is employed with three leather rings 6 inches in diameter and 3-16 inch in thickness. Through these pass bolts which are extended to form the clutch brake. The flexible leather takes up any misalignment between clutch and gearset and makes the clutch action smooth. Right—Three-plate dry-disk clutch used on Jeffery Chesterfield for 1915

of an automatic cutout, disconnecting the generator from the battery when the engine is stopped and preventing the discharge of the battery and the burning out of the generator. When the lamps are lit and the engine is running the output of the generator automatically is increased to take care of the additional lamp load.

The starting motor, which is mounted on the left side of the engine, has a square armature shaft on which is a sliding pinion. The latter meshes with gear teeth on the flywheel. The armature is designed to stand the momentary high speed when the engine first begins to fire and before the starter is released.

When the starter pedal is pushed down the switch makes preliminary contact, closing a circuit through a resistance which cuts the current sufficiently to cause the armature to rotate slowly until the gears are meshed, when the final contacts are made and the engine rotated at about 165 revolutions per minute.

Six Degrees of Headlight Brilliancy

Lighting is controlled by a switch by which various combinations of lamp filaments are obtained to provide six different degrees of brilliancy. There are no side lamps. The headlamp bulbs each have two filaments, one of which is at the focal point of the reflector, and the other about 1 inch ahead of this point. The filament in focus throws a beam of light directly ahead of the car for country driving, while the one out of focus is used for city driving, and gives a light which is not dazzling, and which will pass the requirements of most city ordinances. If a still dimmer effect is desired, this may be secured by other positions of the switch. In fact, six different degrees of brilliancy are obtained by different combinations of the four filaments in the two bulbs. The filaments can be used separately, in series parallel, or all four in series, or all four in parallel.

Tapering Charging Is a Feature

Tapering charging as worked out in the Bijur system is a feature in that voltage regulation is obtained instead of current regulation, so that the quantity of charge varies with the needs of the battery. Curves taken at the Jeffery plant of the generator output at varying speeds show a maximum of 14 amperes available with a battery at 1.150 gravity. The maximum output of the generator is 25 amperes, leaving an ample reserve for light.

With the battery discharged, the generator output is 12 amperes, which decreases as the battery is charged until a point of 2 amperes charge is reached, at which it remains constant. If during this time, the lamps are lit, the generator output will increase by the amount of the lamp load up to the maximum capacity of 25 amperes.

Clutch Action Is Smooth

Between the three-plate dry-disk clutch and the gearset is a new form of the leather universal coupling which made its first American appearance on the 1914 Jeffery cars. However, the design has been altered somewhat, so that instead of the double type, a single type is employed in which there are three leather rings about 6 inches in diameter and 3-16-inch in thickness. Through these pass bolts which are extended to form the clutch brake. The flexibility of the leather is depended upon to take up any misalignment between the clutch and the gearset, and makes the transmission of power from clutch to gearset soft, so that the effect is the same as if an even smoother clutch action were obtained.

The bolt passing through the couplings are longer than necessary for this purpose, but carry at their forward ends a pad held on the bolts by springs. This, when the clutch is released, presses against the clutch and prevents clutch spinning.

Four-Speed Gearbox with Center Control

The gearshift lever has been arranged for central control on the four-speed gearbox, and is a part of it, that is, it extends directly from the latter without cross rods. Power is transmitted from the gearset to the axle through a propeller shaft in which a special universal joint is incorporated at each end. An unusual feature is the fact that the propeller shaft is tubular instead of the solid cross-section usually employed. This makes a light shaft and one which is very rigid.

At the rear end of the propeller shaft is mounted the over-type worm and gear of the axle. The worm drive which replaces the bevel gearing of the 1914 Jeffery is an unusual construction in cars of the price classification into which the Chesterfield falls.

Gear ratios provided through the four-speed gearset and the worm final reduction are 13.77 to 1 on first, 7.71 on second, direct on third at 4.50 to 1, fourth 3.73 to 1.

The floating axle has shafts of chrome-nickel steel mounted on imported annular ball bearings. The frame is of unusually heavy pressed channel steel and is arranged to come directly under the sills of the body to make the whole car more rigid. This is a new feature in the Jeffery design.

Suspension in the Jeffery, six-cylinder car is a departure for the Kenosha factory in the employment of the cantilever type of rear spring. The factory officials call it the floating cantilever because of the particularly easy-riding qualities it gives the car. The rear springs are 48 inches long and 2 1-2 inches wide. Front springs are conventional and are 37 inches in length and 2 inches in width.

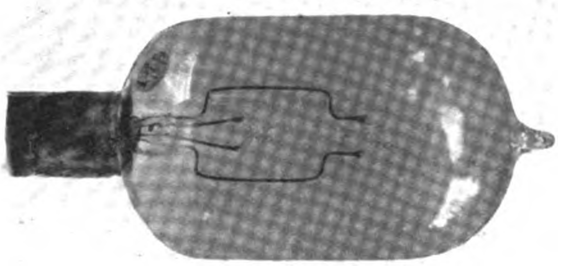
Gemmer worm and sector type of steering gear is employed having an 18-inch wheel with corrugated rim and with the electric horn button located at the top of the post. There are two sets of brakes, both internal expanding, operating on pressed steel drums 14 by 2 inches. Demountable rims, of a type which the Jeffery people say is not addicted to squeaking, are part of the stock specifications.

Streamline Bodies and Crowned Fenders

Bodies are of the streamline type, fenders are crowned, and are stamped in one piece. Running boards are clean, and the lines of the cars as a whole are particularly smooth. In the touring car, which is marketed as a five-passenger car, there is sufficient room in the tonneau for two extra disappearing seats, and these are supplied at a slight additional cost. The five-passenger in touring trim tips the scales at 2,850 pounds.

Speedometer Has Empico Drive

Aside from the rather unusual equipment which already has been mentioned, there is supplied a Stewart speedometer with the Empico drive through the steering knuckle and axle shaft, a Weston ammeter, sight-feed oil indicator and Klaxet horn under the hood.



Bulb used in new Jeffery headlights. The bulbs each have two filaments one of which is at the focal point of the reflector and the other about 1 inch ahead of this point. The filament in focus throws a beam of light directly ahead of the car for country driving, while that out of focus is used for city work and gives a light which is not dazzling and which will pass the requirements of most city ordinances. Still further dimming may be effected by other positions of the switch by which, in fact, six different degrees of brilliancy may be obtained by different combinations of the four filaments in the two bulbs. The filaments can be used separately, in series parallel, all four in series, or all four in parallel

New Moon Equalizer Has Twenty-Eight Less Parts

ST. LOUIS, MO., July 20—The tendency of the automobile manufacturer of today to lessen the number of parts in his car in order to make it as trouble-proof as possible is indicated by the adoption by the Moon Motor Car Co. of a patent brake equalizer, invented by Chief Engineer Goodspeed. The new equalizer will be a part of the regular equipment of all Moon cars.

The new equalizer has twenty-eight less parts than the one in ordinary use, having only twenty-two parts as against fifty, including brake arms, eveners, bolts, rods, springs and cotter pins.

The ordinary equalizer connects the hand lever and pedal with the rear rod by four connecting rods, necessitating an extra pair of brake levers and eveners, connected with a shaft running across the center of the frame, and giving indirect brake action.

The Moon equalizer has the eveners located in the connection with the rear rod and only two brake levers and two rods are used. The new arrangement gives more direct action and eliminates danger of the mechanism binding.

In THE AUTOMOBILE for June 25 an article entitled The Best Automobile Upholstery Leather Comes from France, should have been credited to President Joseph W. Moon, of the Moon company. Through an oversight, credit was not given.

Hudson Distributor Installs New Service

NEW YORK CITY, July 20—The A. Elliott Ranney Co., distributor of the Hudson car in this city, has announced a new service plan, beginning Aug. 1, 1914, which will greatly benefit its customers. By this new plan the customers' cars will be kept in first-class running order and free from undue "lay-ups."

According to the new policy cars will be tested at least once every 30 days and such minor adjustments as may be found necessary will be made free of charge to the owner from 1 year from the date of delivery.

All parts proved to be defective will be replaced free of charge, this question to be determined by an expert from the Hudson factory, who will visit the service department at least once each week regularly throughout the year.

This inspection will be made under systematic arrangements, which have been inaugurated in the form of a card system bearing the name and address of the owner, the date of delivery and the date in each month when the car is to be brought in by the owner for inspection.

The Use of Tire Flaps

SCORES of owners are almost daily experiencing troubles with pinched inner tubes due to not using flaps in the casings. It is practically impossible to avoid pinching the tubes if flaps are not used, and this is particularly true with over-size tires in which a smaller tube is used. Using a tube fitted to the size of the casing will not entirely eliminate the difficulty, in fact, there is but one sure way to avoid pinching and that is using the flap.

Flaps like all other parts of the tire require occasional attention. The edges of the flap get dried and curl up, it often happening when the flap is put in place after the tube is in the casing, that the thin edge of the flap does not lie straight in the casing and may have a wrinkle or two in it. Wrinkles in the flap will pinch the tube just as surely as wrinkles in the fabric of the casing will do so.

Not infrequently a flap gets torn in case of a puncture, where the car may be traveling rapidly and the brakes are too suddenly applied, or the power left on after the tire has become deflated. It is but natural to return the torn flap and to endeavor to adjust it within the casing, but it is most common to have a pinched tube as a result of this.

Tube pinching is one of the most prolific of tire difficulties and it can to a large measure be overcome by very careful attention to the flaps.

Positively-Operated Valves

TWO cams for the actuation of each valve, one cam to open the valve and the other cam to close it, give promise of attracting very general attention in engineering circles in Europe where the development of specially high-speed motors is in question.

Five cars started in the recent French Grand Prix race with positively-operated valves, and, although none of them proved winners, the method of valve actuation was not only demonstrated to be feasible but entirely satisfactory. The failure of the cars fitted with positively-operated valves was not in any sense due to troubles with the valves but rather with other parts of the cars.

The entry of positively-operated valves in these days when regulations are cutting the dimensions of motors for racing down to limits unthought of 5 years ago, comes at a most opportune moment.

Heretofore the closing of the valve has been the one great limiting factor in speed; in fact, it is today a greater problem to be reckoned with than the reduction of weight in reciprocating parts. Several years ago one of the foremost American racing concerns demonstrated to its own satisfaction that when its motor was working at over 2,500 r.p.m. the exhaust valves were not seating at all. A condition of this nature meant considerable loss in power due to loss in compression, and what the speed possibilities might have been had the compression been conserved remains to be estimated. The same was true with regard to the intake valves.

The positively-operated valve gets away from the trouble of failure of closing. It makes the poppet valve as positive as the sleeve valve, but leaves as it has been the question of relative area of opening afforded by the valves.

The positively-operated valve is today much more of a reality than the use of four valves to one cylinder. There are restricting factors of expense to be considered when placing four valves in each cylinder, but on the other hand the cost factor in installing an extra set of cams with the necessary actuating parts is not so great.

Should the positive-operated valve be adopted in stock models there promises to be considerable litigation in the patent circles because already some of the large European interests have gotten control of the basic patents on this design and with many concerns entering the field there would, without question, be a bewildering turmoil of patent litigation.

This year's Grand Prix race is today justifying the predictions made concerning it, namely, that its limitations of piston displacement and weight would bring factors into the automobile field that up to the present have received but scant attention. Much good has already come from the race and the lessons of it are but in the primary stages. It has opened new possibilities in the automobile field, and whether these lessons receive early application in regular models or not, the fact remains that new avenues of motor design have been opened by the race and its regulations.

Exports of Cheaper Cars Increasing

Shipments Abroad of Passenger Cars Made in the United States Grow from 3,036 in May, 1913, to 3,256 in 1914, But Value Is Less—Fewer Commercial Vehicles Moving

WASHINGTON, D. C., July 18—While the exports of commercial cars show a sharp decline in May last as compared with May a year ago, pleasure car exports show a decided increase in number but a slight difference in value. The figures for these periods, together with those for the 11 months ended May, 1913 and 1914, as compiled by the federal bureau of statistics, are presented below.

Exports of tires for motor cars show a slight decrease in value, according to the latest figures compiled by the federal bureau of statistics. The figures show that these exports were valued at $396,816 in May, 1913, while in May last they were only valued at $368,745. During the 11 months' period ended May the exports decreased in value from $3,512,095 in 1913 to $3,052,089 in 1814. The figures, by countries, are given below.

Exports of parts, not including engines and tires, increased in value from $537,511 in May, 1913, to $600,793 in May last, and from $4,690,983 to $6,150,264 during the 11 months' period. These figures in the tabulation tell the story how imports of cars have fallen off.

CAR EXPORTS	May 1913 Number	May 1913 Value	May 1914 Number	May 1914 Value	Eleven Months Ending May 1913 Number	Eleven Months Ending May 1913 Value	Eleven Months Ending May 1914 Number	Eleven Months Ending May 1914 Value

Cadillac Engine Runs 90 Days at 600 r. p. m.

JERSEY CITY, N. J., July 18—After running 90 days and reeling off 50,000 miles, the 1914 Cadillac stock engine that was started on the morning of April 8, ceased to revolve last evening. The engine, after being placed on exhibition for a while at the Crescent automobile showrooms, 2565 Boulevard, this city, will be shipped to the Cadillac plant, Detroit, for a thorough inspection.

The motor has been run at from 600 to 700 revolutions per minute, making about 535 miles a day, or a little over 22 miles per hour.

Ohio City Cars Must Be Registered

COLUMBUS, OHIO, July 20—Attorney-General Hogan was called upon recently to give an opinion on the question if cars owned and operated by municipalities in Ohio would have to be registered. The same question was brought before the attorney-general several years ago and decided that all motor cars in the state must be registered. The city solicitor of Cincinnati was not satisfied with this opinion and the question was again opened. Attorney-General Hogan ruled that all municipal motor cars must be registered with the state department.

Addition to Stearns Factory of 500,000 Square Feet

Five Stories of Latest Design Will Be Begun in August—Will Mean Doubled Output

CLEVELAND, O., July 18—The F. B. Stearns Co. will break ground in August for a new factory building to adjoin the present plant at 12963 Euclid avenue. The new plant will have 150 feet frontage on Euclid avenue and contain 500,000 square feet of floor space.

Plans for the structure were drawn by Albert Kahn, Detroit architect, who designed buildings for Chalmers, Ford, Hudson and other manufactories. Bids have been received from a number of contractors. The new addition will be five stories high, of concrete and steel construction and absolutely fireproof. The designs call for unique type of building work and were determined upon only after Stearns officials visited a number of automobile factories over the country.

President F. B. Stearns declared the output will be more than doubled by means of the new buildings and that the 1915 series prospects make the move for more room imperative. "We have been unable to meet the demands for our cars," said he. "That is why we believe we suffered last winter from moral depression rather than business languour."

Over $1,000,000 in New Machinery

The Stearns company placed orders for more than $1,000,000 worth of new machinery and planned building expansion several months ago.

Along with the Ford assembly plant and the establishment of the Richard Automobile Co. in a factory of its own as prospects of the immediate future, several other Cleveland makers are said to be planning factory expansion.

New Medium-Priced Car in the Fall

The fact that the Stearns factory is making ready to produce for fall sales a medium-priced car has direct bearing on the demand for more space.

The body department which has been maintained in the old Royal Tourist plant will be removed to the parent factory as soon as the new addition is completed. The separation of this from the other departments of the Stearns plant has always been considered inconvenient.

Market Reports for the Week

Prices in general were steady in this week's markets. Pennsylvania petroleum dropped $0.05 per barrel due to overproduction, with a like reduction in Europe in sympathy with that on this side. Antimony came down $0.00 1-2 per pound, closing at $0.05 1-4. Both electrolytic and Lake Coppers declined, the former $0.00 1-5 and the latter $0.00 1-4 per pound. Cottonseed oil closed at $7.23 a barrel, a loss of $0.09 for the week. Tin rose $0.10 per 100 pounds. The crude rubber market was dull without features. Up-river Para rose $0.01, closing at $0.71.

Overland Plant To Be World's Largest

TOLEDO, O., July 18—Within a few weeks when the main building of the several which are under construction for the Willys-Overland Co. iscompleted the home of the Overland will have over 1,000,000 square feet more space and will occupy all-told 60 acres of floorspace distributed among 64 buildings. It will make the local automobile concern one of the largest of all manufacturing plants in the world, all industries considered.

The new main building is a four-story structure 500 feet long and 410 feet wide, built entirely of reinforced concrete on a foundation of concrete piling. The four floors will be used for body building, upholstering, painting, assembling and machine shops, while the basement will be used as a storage room.

The second largest new building will have two stories, 400 by 200 feet, and will be used exclusively for making coupés and open bodies.

The new power plant of structural steel faced with brick will be 162 feet long and 134 feet wide, the power being furnished by 4 McNaul water tube boilers, each capable of developing 500 horsepower. The chimney, 205 feet high, will be one of the highest in this part of the country.

In the rear of the new body plant a drying kiln, 236 feet long and 144 feet wide, has been installed. It has a capacity for handling 12,600 feet of 1-foot lumber per 24 hours. The blacksmith shop is being enlarged through the addition of a two-story building having 7,000 square feet of floorspace. Under the railroad tracks a tunnel is being constructed which will permit mechanics to take the cars to and from the testing oval without crossing the tracks.

General Motors Cancels $2,000,000 in Notes

NEW YORK CITY, July 20—The General Motors Co. has purchased for the sinking fund $2,000,000 of its 6 per cent. first lien 5-year gold notes in anticipation of its obligation to pay $2,000,000 cash October 1 to the trustee for sinking fund purposes.

With the cash deposited, a total of $7,099,000 notes have been purchased, leaving outstanding $7,901,000 of notes which mature on October 1, 1915.

The current fiscal year, which ends July 31, is proving a very prosperous one for the company.

There were originally issued $15,000,000 of the notes. The sinking fund requirements were as follows: $1,500,000 cash to be paid to the trustee on or before October 1, 1911; $1,500,000 cash on or before October 1, 1912; $2,000,000 on or before October 1, 1913, and $2,000,000 on or before October 1, 1914.

Ford's Sales for 9 Months, 203,194 Cars

DETROIT, MICH., July 21—The Ford Motor Co. has built and sold 203,194 cars from October 1, 1913, to July 1, 1914. In other words, an average of better than 22,500 Fords have been built and sold every month for the first 9 months of the company's fiscal year. Last year's production of Fords was about 185,000 cars. This mark was passed by this year's production in the middle of May.

Lansden Co., Ltd., Moves to Brooklyn

NEW YORK CITY, July 22—The Lansden Co., Ltd., has been formed by J. B. Wickery and associates, who have purchased the rights, patents and parts of the former Lansden company, of Newark, manufacturer of the Lansden electric truck. Mr. Wickery has removed the business to Brooklyn, where he will hereafter manufacture that vehicle and conduct a general garage and repair station.

Mr. Wickery has been manager for the trustee of the old Lansden company, since the trusteeship was created about a year ago. At the sale of the property on July 13, he purchased the name and good will of the company and has since acquired all patents, parts, patterns and plans which were purchased at the same sale by the New Jersey Machinery Exchange. The incorporation of the Lansden Co., Ltd., is now in progress with a capital stock of $250,000.

The property has been removed to Flatbush, where the company has leased the factory buildings between Flatbush and Nostrand avenues and the Long Island Railroad, formerly occupied by the J. R. Corbin Co. This property has a floor space of over 13,000 feet with direct trackage to the Long Island system.

The new company is not only in the market with the new Lansden truck, but proposes to conduct a general repair business in both gasoline and electric trucks at once. The new line will comprise electric units from 1,000 pounds to 5 tons capacity. There are about 1,000 Lansden cars in operation now.

Pope Plant To Be Auctioned in Month

HARTFORD, CONN., July 18—Col. George Pope, receiver for the Pope Mfg. Co., has been authorized by the court to sell at public auction that personal property of the company which is in Hartford, Conn. It is likely that it will mean the end of the Pope company as a motor car manufacturing enterprise. Other property, including the bicycle plant, is located in Westfield, Mass., but this is within the jurisdiction of Massachusetts courts. The motor car plant is in Hartford.

Colonel Pope regards it as better to sell the machinery and equipment in small lots to avoid its being taken in one parcel by junk dealers. He expressed his belief that the small lot sale will bring in a greater return and it is hoped to secure a small payment for the preferred stockholders. Under all plans previously proposed it had not seemed possible to secure much, if anything, for them.

Business at the Hartford factory, which has been continued in part by Colonel Pope, is to be discontinued as soon as possible. It is expected that the plant will be shut down by August 20. The receiver has $130,000 on hand and a dividend will be paid to creditors before September 30, it being regarded as more advisable to pay out the money than to keep it and pay taxes on it.

Warm-Hand Steering Wheels for All Cars

POUGHKEEPSIE, N. Y., July 18—The Warm-Hand steering wheels which have been marketed for 2 years for Ford cars will be supplied as interchangeable wheels for Overland and Studebaker cars this fall. The Warm-Hand Steering Wheel Corp., Poughkeepsie, N. Y., manufacturer of these wheels, is further going to supply specially constructed wheels to fit any make of car. These wheels will be interchangeable with the standard steering wheels, the same as on Fords, Overlands and Studebakers. The heating device in these wheels consists of two electrical resistance coils inserted at opposite points in the rim of the wheel. Electric current to heat these coils is furnished from the battery.

Swinehart Tire & Rubber Co. Dividend Paid

AKRON, O., July 18—Shareholders of the Swinehart Tire & Rubber Co. have received checks for the usual quarterly dividend of 1½ per cent. a month ahead of time. The company has decided to discontinue the policy of paying the dividend a month after it is due. The last previous payment was made on May 10.

Automobile Securities Quotations

NEW YORK CITY, July 22—The automobile securities market for the past week showed practically the same inactive tone which has been apparent for some time. The feature of the week was the slight gain by the tire companies, Goodyear common gaining 4 points and the preferred 1-2 point. Goodrich preferred showed a gain of 3-8 while the common dropped 2 1-4. Oil stocks continued weak, vacuum oil losing two points, while Texas remained unchanged. The stocks of the automobile and truck manufacturing companies suffered practically no change, the entire market for these stocks being very inactive. The general weak tone of the market affected Willys-Overland, the common losing 1-4 point and the preferred 1 1-2 points. Full quotations for the past week follow:

Detroit's Exports in 6 Months $3,154,875

Michigan Export of Cars and Trucks for Half Year Total 4,207—3,324 of These Manufactured in Detroit

DETROIT, MICH., July 18—During the first 6 months of 1914 out of 4,207 pleasure and commercial cars which were exported from the state of Michigan to foreign countries, 3,324 or 79 per cent. were manufactured by concerns located in Detroit. The value of the cars exported by Michigan manufacturers is $3,942,423, of which $3,154,875 is to the credit of Detroit. Including parts and accessories the total export for the state was $5,819,489 of which $4,752,268 is credited to Detroit manufacturers.

A comparision with the export business during the first 6 months of 1913 for the whole state of Michigan is not possible as only since the beginning of this year the customs department is keeping a separate record, but the figures were obtained for the city of Detroit.

From January 1, 1914, to June 30, Detroit manufacturers exported 3,205 pleasure automobiles valued at $3,030,251 or an average of $945 per car while during the corresponding period in 1913 a total of 2,149 pleasure cars were exported having a total value of $2,542,937 or an average of $1,183 per car. The increase in pleasure vehicles exported this year is thus 49.1 per cent. In total value it represents an increase of 19.1 per cent. The number of commercial cars exported was 119 having a value of $124,624 or an average of $1,047 per vehicle, while during the first half of last year 177 utility cars having a value of $165,209 were exported, their average price being $933. There has thus been a falling off of 32.8 per cent. in the number exported and 24.5 per cent. decrease in total value.

Automobile parts and accessories of a total value of $1,597,393 as against $1,404,082 for the first half of 1913, have been exported which represents an increase of business of 13 per cent. in favor of this year.

Of the 3,205 pleasure vehicles exported between January 1, and June 20, 1,785 or 55.5 per cent. went to England. Their total value was $1,302,868 or $780 per car; 1,056 or 32.8 per cent. having a total value of $1,359,529 or $1,297 each, were shipped to Canada; 184 or 5.7 per cent. having a total value of $133,033 or $723 each, went to Australia; 95 or 2.9 per cent. went to South Africa, their total value being $72,676 or an average of $714 per car; 78 were exported to New Zealand, their value being $63,170 or $810 each; 6 cars of an average value of $801 each were sent to Japan and one went to China being valued at $4,169.

Of the 119 commercial vehicles exported 87 or 73.1 per cent. went to England. They had a total value of $71,702 or $824 per vehicle; 30 were shipped to Canada, their total value being $50,773 or $1,693 each; one went to New Zealand valued at $1,248 while one was shipped to South Africa, it being valued at $901.

Of the $1,597,393 worth of parts 90 per cent. is credited to Canada, 3.5 per cent. each to England and Australia and the remaining 3 per cent. is divided among South Africa, New Zealand and Japan.

Chamber of Commerce in Summer Session

CHRISTMAS COVE, ME., July 21—*Special Telegram*—Samuel Miles, erstwhile general manager of the National Automobile Chamber of Commerce, and previous to that manager of the Automobile Board of Trade, and the National Assn. of Automobile Manufacturers, is entertaining officers of the N. A. A. C. and their guests to the number of twenty-two at his summer home, Clifton, overlooking the Atlantic Ocean at this point.

Entertainment is one of Mr. Miles' strong factors, and since the arrival of the guests here last Saturday, both he and Mrs. Miles have been excelling themselves. Fishing, baseball, shooting and swimming, have been the recreation, the blues beating the grays in the annual baseball struggle.

But it is not all pleasure as the N. A. A. C. will devote one day to business routine, this meeting taking the place of one of the regular ones in New York.

Among those present are: Col. Chas. Clifton, president, N. A. A. C.; W. C. Leland, first vice-president; H. H. Rice, second vice-president; and directors C. C. Hanch, W. E. Metzger, and L. H. Kittredge. Among the others present are: R. D. Chapin, Thos. Henderson, H. M. Swetland, S. D. Waldon, D. J. Post, Chas. Thadeus Terry, Geo. Pope, Albert Pope, W. M. Sweet, F. C. Billings, F. A. Nickerson, S. Edwards, Chas. E. Thompson, Robert E. Garden and T. Wetzel. Alfred Reeves, general manager of the N. A. A. C., is acting as Master of Ceremonies.

Chalmers Men Optimistic on Trade Conditions

DETROIT, MICH., July 21—*Special Telegram*—About 450 dealers from all over the country attended the annual convention of the Chalmers Motor Co. held at Cedar Point, O., July 17 to date. The new models were shown for first time on the boat taking party to convention place.

President Hugh Chalmers in his address said: "If anyone questions the economic soundness of the automobile industry I recommend him to visit Detroit. Detroit is the biggest part of the automobile industry and Detroit is more prosperous right now than scores of cities with big manufacturers in other lines. The country envies Detroit its prosperity, simply because Detroit men have been wise enough to build up in their city this great industry which is the wonder of the world. With crops reaching a record mark, I do not see how the country can endure any serious or protracted slump."

Preliminary Injunction for National Carbon

NEW YORK CITY, July 17—A preliminary injunction has been handed down in favor of the National Carbon Co. in its suit against the Bright Star Battery Co. in the U. S. District Court for the Southern District of New York. The suit, which involves the use by the Bright Star Company of the words "Mars-Chlor" and "Tun," as well as the use of certain numbers, was brought June 29. The preliminary injunction is issued under date of July 17.

In the terms of the injunction, the Court enjoins the Bright Star Battery Co. and all its agents, employees, etc., at the end of 20 days and during the pendency of the suit from using the word "Mars-Chlor" or the syllable or word "Tun" on "batteries, or on the cartons, containers or wrappers or on price lists, circulars or other printed or written matter in connection therewith, or the numbers from 1,600 to 1,699 or from 1,700 to 1,799 in the positions in which they have been heretofore used."

Two Receivers for U. S. L. Company

BUFFALO, N. Y., July 22—*Special Telegram*—Judge John R. Hazel of the Federal Court here, has appointed James E. Roberts and James O. Moore receivers for the United States Light and Heating Co. of Niagara Falls, N. Y. Louis S. Posner, of the law firm of Dos Passos Bros., of New York City consented to the appointment of a new receivership upon the filing of an equity action against the company by Alfred Stickney, of New York City. The action was instituted by the Central Trust Co., which has a claim of $450,000, said to be a preponderance of the indebtedness of the company. Yesterday Mr. Posner made a motion to have stricken from the records of the court the answer of A. Henry Ackerman, of Niagara Falls, vice-president of the company, admitting allegations of fraud and mismanagement in actions brought by the Picher Lead Co., of Joplin, Mo., and consenting to a receivership. Mr. Moore was appointed receiver last week.

Walpole Creditors May Get 10 Per Cent.

BOSTON, MASS., July 20—Attorney R. G. Curtis, representing the reorganization committee, informed Judge Dodge in the U. S. District Court today that if the reorganization of the Walpole Tire & Rubber Co. as planned was effected, creditors would get 10 cents on the dollar. Claims amounting to approximately $1,750,000 have been presented and it is estimated that these claims will be reduced $500,000 before they are allowed.

The receivers report cash on hand amounting to $130,000 and cash on special deposit of $63,000. On the question of additional compensation for the receivers, attorneys for the creditors suggested $5,000 each for the receivers and $10,000 counsel fees.

Pending an agreement on what should be paid at this time the matter was continued, the receivers have requested $35,000. They have already received $18,000.

New Packard Patent Has Broad Claims

DETROIT, MICH., July 20—I notice in your current issue your reference to another patent of Edward P. Cowles, which was issued to the Packard company on the 14th instant. The inference might be drawn from your article that this patent relates only to removable and interchangeable wheels, whereas as a matter of fact some of the claims cover the steering knuckle and bearing arrangement without regard to the removability of the wheel.

A close analysis of the patent shows that claims 7 to 11 and 16 to 18 relate to removable and interchangeable wheels, and claims 12 to 15 to removable wheels regardless of interchangeability.

Claim 5 also covers a detachable wheel but relates more particularly to the arrangement of the trunnions of the steering knuckle between the inner and outer hub members.

Claims 1 to 5 and 6, I believe, cover broadly the use of a wheel and steering knuckle in which the inner of the two ball bearings is approximately vertically in line with the point of contact of the tread of the wheel with the ground, and claims 2, 3 and 4 relate to such a wheel and bearings with an inclined steering spindle.

I think claim 4 is a fair example of this group of claims, and reads as follows:

> "In a motor vehicle, the combination with the front axle, the stepped spindle pivoted thereto, a large bearing mounted at the base end of said spindle, and a smaller bearing mounted at the outer end of said spindle, of a wheel having a hub mounted on said bearings and inclined so that the point of contact of the tread thereof with the ground is approximately vertically in line with the inner and larger of said bearings."

While undoubtedly the detachable and interchangeable wheel feature of this patent is of considerable interest to the industry due to the fact that the wire wheels that are now being introduced are made both removable and interchangeable, yet I believe that the inclined steering knuckle feature is fully as interesting, and is likely to prove as important, or more so, to the industry at large.—Packard Motor Car Co., MILTON TIBBETTS, patent counsel.

Four-Wheel Drive Co. Holds Annual Meeting

CLINTONVILLE, WIS., July 17—The annual meeting of the stockholders of the Four-Wheel Drive Auto Co. was held in this city on July 14. Chas. Hagen, of Black Creek, Wis., and Chas. Folkman, of this city, who have been identified with the company since its organization, were re-elected. The board of directors was increased from seven to nine members. A. Kuckuk, of Shawnee, Wis., and A. W. Priest, of Appleton, Wis., were elected as directors.

W. A. Olen, John Kalmes, Frank Gause and D. J. Rohrer were respectively re-elected president, vice-president, secretary and treasurer.

The company expended about $50,000 in the past year for permanent improvements to its factory and in machinery. A dividend of 4 per cent. on all stock outstanding on June 30, 1914, was declared and paid in cash.

The sales for the past year for its trucks showed an increase of 165 per cent. over the previous year.

Changes Name to Metal Auto Parts Co.

INDIANAPOLIS, IND., July 17—The Schiedel-Thompson Mfg. Co. has changed its name to the Metal Auto Parts Co. The management and stockholders remain the same as in the old company.

Marsh To Make the Caesar Light Car

ANDERSON, IND., July 16—A. R. Marsh, formerly connected with the Vulcan Mfg. Co., Painesville, O., maker of the Vulcan car, has disposed of his interests in that company, which he organized and whose product he designed throughout. He will enter the field of lighter, lower-priced cars. The new car will be called the Caesar.

Two Jets and Three Air Valves on New Rayfield

CHICAGO, ILL., July 20—The new Rayfield model G carbureter, which is the successor to the model C made by the Findeisen & Kropf Mfg. Co., is characterized by three air valves and two gasoline jets. The carbureter is similar to the model C, and the adjustments are the same except that the air valve adjustment has been eliminated entirely. The primary jet supplies all the gasoline required when the motor is idling and the auxiliary jet is controlled by a metering pin which is gradually brought into play as the speed of the motor increases.

The three air openings are also automatic. The primary air opening is fixed and the other two are operated by the suction of the motor. These valves are shown in the sectional view on this page. The fixed air opening is at A, and the auxiliary air valves B and C operate together in connection with the piston D in the auxiliary gasoline chamber E. The purpose of the piston is to prevent the air valve from fluttering on sudden throttle changes or other difficult conditions. The upper air valve B operates the metering pin F, which supplies an increasing amount of gasoline in direct proportion to the amount of air admitted. This auxiliary jet is not in operation until the motor has increased its speed sufficiently for the suction to open the valve B.

There are only two adjustments, low and high. Both control the amount of gasoline. These adjustments are shown on the exterior view of the carbureter at L, and H L controls the low speed and H the high speed. These carbureters have been adopted as standard on the Winton, Chandler, Chalmers, National, Jeffery, Lozier, Haynes and other cars, and negotiations are under way for other makes.

A New World's Dirt Track Record—25 Miles in 22:07 1/5

Barnes in Romano Establishes New Mark at Portland, Ore., in Struggle with Tetzlaff and Carlson in Maxwells

TACOMA, WASH., July 20—In the free-for-all at the Rose City track, Portland, Ore., July 12, Percy F. Barnes, in his Romano, hung up a world's record for 25 miles on a dirt track of 22 minutes 7 1-5 seconds. He drove a sensational race against Tetzlaff and Carlson in their Maxwell mounts.

This is the fastest time ever made on the Portland track. Tetzlaff suffered a slight engine trouble on the twenty-first mile which lost him a quarter of a lap and the race. Brock, in his Wright special, traveling in second place in the sixth lap, went out in the seventh with a flat tire.

In the first heat of the 3-mile event Tetzlaff won from Brock in 2 minutes 37 seconds. In the 5-mile race from a standing start Barnes in Romano won in time of 4 minutes 30 seconds. The second heat of the 3-mile free-for-all open was won by Tetzlaff, thus giving him the race without a deciding heat. He did the 3 miles in 2 minutes 36 2-5 seconds, Brock again taking second and Barnes third.

"Plucky" DeAlene went into the race with a badly crippled Marmon, but managed to make the circuit twenty-five times without going through the fence, although his transmission was faulty and several spokes in his rear wheels broken. The attendance was fair for a combination motorcycle and motor-car exhibition.

A series of accidents occurred on Saturday, July 11, at the Rose City track. Ray Brock, in backing up to the starting line, broke a magneto shaft, which put him out of the race. Kennedy, in his Chalmers six, was just starting when the differential housing gave way and he was No. 2 out in the same race. In practice H. Goetz in a Nyberg Special threw a wheel, and car was unsafe to run and he was out of race.

Of the three Maxwells which started in the first race, only one, Tetzlaff's No. 3, was in running order at the finish. In consequence the program was badly shot to pieces. The track was in fairly good condition, being well oiled.

Maxwell To Retract Speedway Advertising

NEW YORK CITY, July 21—The Maxwell Motor Co., Detroit, has agreed to retract its advertising which followed the Indianapolis race, May 30, when the Maxwell car No. 25 which finished in the race was advertised as the Maxwell "25," which is the regular model of the company.

The contest board of the American Automobile Assn. took the matter up at its meeting last week and decided that the Maxwell company would have to publicly retract by publishing an advertisement in one of the daily papers in each city and town in which the original advertisements had been published. In addition the retraction will be made through the weekly and monthly class publications. With the retraction goes a cash fine of $500.

The advertisement frankly states that there is not any similarity between the Maxwell No. 25 which finished the Indianapolis race and the Maxwell "25" which is being regularly sold to the trade.

Clifford Ireland, Peoria, Ill., was appointed contest board representative for Illinois.

Omar Taft was suspended by the board until Jan. 1, 1916, for his connection with the entry of a Delage car and its failure to take part in the recent Santa Monica races.

The Detroit track, on which the recent cyclecar meet was held July 4, was suspended until January, 1915, this being a licensed track under the A. A. A. The suspension was for issuing sanction to the cyclecar organization which sanctioned the meet.

Firestone Factory Foremen Hold Outing

AKRON, O., July 21—A party composed exclusively of 170 superintendents and foremen of the Firestone Tire & Rubber Co., this city, held an outing on July 11 at the Old Firestone Homestead, 80 miles away, H. S. Firestone was host. After dinner there was a ball game. There were also many other games.

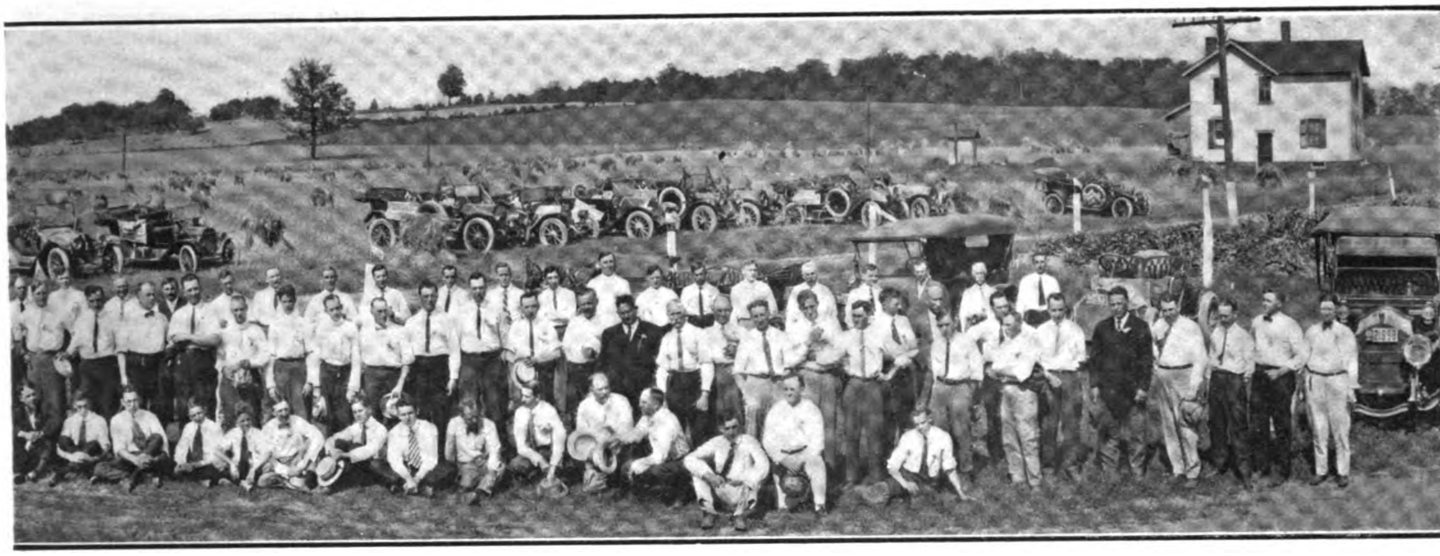
DePalma and Burman in Elgin—10 Entered

CHICAGO, ILL., July 21—Ralph DePalma with the German Mercedes that won the French Grand Prix, and Bob Burman with the Peugeot, are the latest entrants for the Elgin Road Races, August 21-22, each being entered in both events. This makes ten entered to date: Two Marmons, two Peugeots, two Sunbeams, two Stutzes, the Mercedes and Rickenbacher's Duesenberg. The Rudge-Whitworth Company, Ltd., which announced that it would offer prizes for the first race, has extended its offer to cover both races. Prizes are to the car coming in first, $200; second, $100.

It is expected that two Mercer cars again will be entered. Spencer E. Wishart, who is now spending his honeymoon in Europe, will return to this country in ample time to tune up one of the Mercers for the Illinois meet, and Edward Pullen, driver of the winning Grand Prize Mercer, is now on his way back from the Pacific Coast and will get the second car in shape.

3-Day Economy Run for Stock Cars Planned

MILWAUKEE, WIS., July 20—An economy run for strictly stock cars, lasting 3 days and covering approximately 575 miles, is planned by the contest board of the Wisconsin State Automobile Assn., as a revival of the annual contest for the *Milwaukee Sentinel* $1,000 trophy, hung up in 1910 by Charles F. Pfister, Milwaukee millionaire and publisher, and already contested for three times in reliability competitions. The running of the event was called off in 1913 because of the



stone, President of the company. There were 170 guests in the party riding in forty automobiles from the factory at Akron to the Homestead, sports were enjoyed

failure of the A. A. A. to issue a sanction because it had no stock car registrations, and the same condition existed this year. So great was the demand of dealers for a Badger contest of some kind that the state contest board today decided to try an economy run. The donor of the trophy has consented to a change in the deed of gift to make this possible. In fact, Mr. Pfister suggested the idea of substituting an economy test for the reliability tour when he was advised that the reliability was an impossibility.

Tentative plans for the 1914 tour fix the dates for Thursday, Friday and Saturday, September 3, 4 and 5. The first day's route is from Milwaukee to Green Bay via Algoma, Wis.; the second, from Green Bay to Madison through the Fox river valley, and the final day from Madison to Milwaukee by way of Janesville, Beloit, Kenosha and Racine. The total mileage of this trip would be 475.

Only stock cars, equipped per catalogue, will be eligible to enter and contesting cars will be graded according to price, number of cylinders, weight including occupants; piston displacement, etc. There will be technical examinations before and after the run and penalties will be inflicted for broken or inoperative parts. The rules will be original with the Badger association, although the 1911 contest regulations of the A. A. A. will be applied to some extent.

Rickenbacher and Mulford at Galveston

NEW YORK CITY, July 21—The entry of Eddie Rickenbacher with his Duesenberg car, Ralph Mulford with his Peugeot and Mel Stringer with another Peugeot, has brought the entry list in the Galveston Beach races on July 29 and 30 and August 1 and 3, up to fifteen.

The list includes the following drivers and their cars:

DRIVER	CAR	DRIVER	CAR
E. Rickenbacher	Duesenberg	Joe Le Cain	Chevrolet
S. F. Duesenberg	Duesenberg	Charles Keene	Beaver Bullet
Bill Endicott	Duesenberg	Conde Moseley	Studebaker
Not named	Duesenberg	H. L. Kindred	National
Joe Horan	Metropol	George Clark	Texas
Not named	Metropol	T. C. Jones	Mercer
Not named	Metropol	Not named	Delage
Chandler	Braender Bull Dog		

It is expected that the crowd at Galveston this year will be greater than at any previous meet. The big event will be the Cotton Carnival Sweepstakes, for which cash prizes amounting to $3,250 are offered. Sixteen events are on the list for the 4 days' racing, and the cash prizes amount to $4,650, in addition to which a number of valuable trophies will be hung up.

Barney Oldfield is expected to participate in the races. At present he is endeavoring to secure a fast car for the meet.

The grandstands, with a seating capacity of over 4,000 people, are more than half completed, and are being built this year of sufficient strength to hold up 8,000.

Brooklyn Dealers Play for a Day on Long Island

NEW YORK CITY, July 21—More than 150 dealers, members of the Brooklyn Motor Vehicle Dealers' Association attended the third annual outing of the organization which was held today at Witzell's Grove, College Point, L. I. The start was made at 10 o'clock from Grant Square in Brooklyn, the procession of about forty automobiles taking well-traveled roads to the Long Island Sound meeting place. In the morning there were two baseball games. Wm. Ellenbeck's team defeating Wm. Severn's 11 to 3 and the Martin-Evans team defeating the Julius Bindrim team 5 to 2; in the play-off, the Martin-Evans team won, the score being 6 to 0. During the afternoon there was the usual program of sports including running, rowing, swimming and wrestling. All told there were more than fifty prizes distributed, most of which were donated by members of the Brooklyn Trade. The affair was brought to a close at a late hour with a vaudeville entertainment and two 10-round boxing bouts.

Overland Business Gains 40 Per Cent.

NEW YORK CITY, July 20—The Willys-Overland Co. closed its fiscal year on June 30 with an increase in output of cars of slightly over 40 per cent. and nearly as large a gain in gross earnings. It is considered the best year in its history.

The net profits are expected to run between $6,500,000 and $7,000,000, or better than 30 per cent. on the $20,000,000 common stock, now paying regular dividends of 6 per cent. The common stock has advanced from 57½ to 90.

Motor Truck Club Discusses Service

NEW YORK CITY, July 21—A meeting of the Motor Truck Club on the evening of July 15 was attended by more than forty representative members and guests. Service, its uses and abuses, was the subject of discussion. Four papers were presented. D. O. Skinner, advertising manager of the International Motor Co., presented a brief paper, in which he described the system of service in vogue at the new plant of that company at West End avenue, 63d and 64th streets, this city. He stated that it was a separate and distinct branch of the business, responsible only to the executive department, and in no sense auxiliary to the sales department. W. L. Day's paper on service from the manufacturer's standpoint was read by C. B. Warren, manager of the New York City branch of the General Motors Truck Co., while J. W. Perry's paper on the same subject was read by D. C. Fenner. Mr. Perry is manager of the New York Lippard-Stewart agency.

Prior to the reading of the papers, President G. H. Duck began the discussion by a strong plea for standardization of service as one of the most important of the tasks now before the motor truck industry. He decried the lethargy of the majority of those interested in the development of the business and urged that manufacturers and dealers and even owners get together and discuss the question with a view to definite action.

Following the reading of the papers, the subject was discussed. The opinion seemed to prevail that efficient service is indispensable, but that it is not fair to render it free to an extent limited to the discretion of the local service manager or of the sales manager. It was agreed that the workmanship and material guarantee should be rigidly adhered to, some even favoring guaranteeing the truck for life in these particulars; but free service was universally condemned.

Sixteen Perfect Scores in Trans-Alpine Run

Of Five American Cars Among Seventy-Five Entries, Only Three Cadillacs Finish

VIENNA, July 5—After 8 days of actual road traveling during which they covered 1,832 miles through the most mountainous sections of Austria, sixteen among seventy-five cars which started in the fifth annual Alpine tour finished with perfect scores. These are: four Audi, one Benz and one Opel cars—all German; three Austrian Daimler, three Italian Fiat, two Belgian Minerva-Knights and one British car, a Rolls-Royce.

Of the five American cars which started in the trial—three Cadillacs, an Overland and a Chevrolet—one of the Cadillac cars finished as a contestant, while the other two completed the tour as non-contestants, after having reached a night control after the scheduled time, and also after having been ditched. One of these Cadillacs also had the misfortune of being supplied with paraffin instead of gasoline, and this was the cause of troubles. The other two American cars met with road accidents on the first day and were withdrawn.

All the cars were driven by either the owner or some gentleman or amateur driver, and this reason accounts for many cars losing points on account of the drivers taking too great chances on the difficult, hilly route.

Few Serious Mechanical Troubles

There were very few cases of serious mechanical troubles, the worst being broken piston rods, broken oil pipes, while there were plenty of minor troubles such as sooted spark plugs, a clogged jet, a leaky gasoline tank. The ditching of cars was also the cause of many points being lost.

The tour was the severest as yet promoted in Europe for ordinary stock cars. Of the 1,832 miles comprising the route, there were 530 miles or 28.9 per cent. over passes of which there were twenty-seven of more than ordinary importance. The slope varied from 1 in 16 to 1 in 4.5. On the Niederalp there were stretches with a 24 per cent. gradient, on the Tauern 23 per cent., and on the Seeberg about 21 per cent. grades were ascended.

Eight cars which had completed the entire route without the loss of a point lost their perfect scores in the final appearance examination, and this gave way to much protesting, as the contestants rightly claimed that the tour was a road test and not an appearance contest.

Sixty-two Cars Completed Tour

From the seventy-five cars which started, sixty-two completed the tour, but of this number only fifty as contestants, the other twelve having lost so many points that they were only considered as non-contestants. Two cars—an N. A. G. and a Laurin-Klement—were disqualified for violation of the rules governing driving through towns. There were 13 cars which did not finish.

Of the 1,832 miles of the tour, 743 miles were over roads which had not been included on previous Alpine trials.

The novelty of this year's tour was the hill climb, and speed trial over a level stretch. The climb was made over a course of about 5.6 miles on the Katschberg, the slope being 1 in 4.8 maximum. A minimum time was allowed each car, being based on the cylinder area, a car with a cylinder area of 2,000 c.c. was allowed 40 minutes while one with 8,500 c.c. or over was allowed but 10 minutes to make the ascent. The fastest time was made by the Rolls-Royce, having a piston displacement of 7,410 c.c. and making the climb in 7 minutes 18 seconds or 4 minutes 27 seconds better than the allowed time. The car which made the best record against its allotted time was the Austin, with a piston displacement of 3,160 c.c., by covering the course in 11:58 or 12:32 better than the scheduled time.

The most difficult part of the tour was the ascent of the Turracher Pass, 38 miles long, with a maximum slope of 10 per cent., but with so many difficult turns, donkey-back bridges, caniveaux and other natural road difficulties, that about 30 per cent. of the contestants lost their clean score in this ascent. Many had recourse to horses to pull their car either because they could not get a going up hill or because they stalled and could not restart.

Contestants were started at an interval of 5 minutes in order to prevent the course being blocked. On some of the other passes the cars were started at 10 minutes' interval.

It was resting day on the third in Trieste and on the next morning the trip to Toblach, 248 miles, was made. The Cadillac driven by Mrs. Boston skidded into soft earth and could not move out without outside assistance. After being again on the course the car came near running down a deep embankment and only a heavy, big stone retained it from a serious accident.

On the ninth day the tourists drove 214 miles. This was the most strenuous part of the tour. The Turracher Pass of 38 miles with its donkey bridges, caniveaux, turns, curves, caused more losses of points than all the other passes caused. Imagine a rise of 2,440 feet within a stretch of 4.8 miles, with several other rising stretches but not quite as bad.

On the tenth day, 221 miles, the speed trials were held over a distance of 3.1 miles. Here, like in the climb, each car was allowed a limited time to cover the distance. The Rolls-Royce covered the 3.1 miles in 2:43 3/5 or 12 seconds ahead of its minimum time. It represents a speed of 68.9 miles an hour. The little Singer made the distance in 4:10 or 49 1.5 seconds better over its schedule.

The Perfect Scores in the Alpine Tour

Car	Bore &	Stroke	Cylinder Displacement
Rolls-Royce, 1	4.48	4.76	7,410
Benz, 1	3.74	5.5	3,970
Audi, 4	3.54	5.5	3,560
Austro-Daimler, 3	3.50	5.5	3,480
Fiat, 3	3.34	5.9	3,400
Minerva-Knight, 2	3.54	5.1	3,310
Opel, 1	3.07	6.1	2,980

Syndicate Buys Sioux City Speedway

CHICAGO, ILL., July 21—E. R. Schultz, secretary of the Sioux City Automobile Club and Speedway Assn., and who managed the recent Speedway and Sioux City race, is at the head of a syndicate which has bought the stock of the other members. The syndicate will convert the present dirt track into a speedway and promote a race next year. A purse of $25,000 may again be offered and the distance will be increased from 300 to 400 miles. It is planned to incorporate for $100,000 with $50,000 paid in. The new company will take charge within 30 days.

$5,000 in Prizes for Motor Pageant

NEW YORK CITY, July 21—Five thousand dollars in prizes to be awarded by the Tercentenary Commission for the best decorated cars in the forthcoming Motor Carnival during the last week in September in connection with the Commercial Tercentenary Celebration. The prizes are to be in the form of trophies or cups for private owners and cash for professional chauffeurs driving the cars which are adjudged winners.

There are to be ten divisions, including those for florally decorated touring cars, florally decorated runabouts, cars with other than floral decorations, ladies' division, electric car, grotesque and burlesque, cyclecar, advertising section, and a division for out-of-town automobile clubs, a large number of which will strive to win one of the three handsome trophies offered in this division.

First prize in the touring car division is valued at $500. In each division there are upwards of seven prizes, in addition to cash awards for chauffeurs. No entry fees will be charged. Artists will design floats free of charge.

Ohio Newspaper Announces Reliability

COLUMBUS, OHIO, July 20—The *Ohio State Journal*, of Columbus, Ohio, is planning to hold a two-day "automobile boosters' tour." Prizes will be given to the winners of the event which will be in the nature of a reliability contest. The dates will be July 29 and 30. The route covers Newark, Lancaster, Circleville, Washington, London, Springfield, Mechanicsburg, Marion, Mt. Gilead, Mt. Vernon and Delaware.

Little Giant Truck on 3,000-Mile Tour

CHICAGO, ILL., July 17—Leaving August 1 a stock four-cylinder Little Giant 1-ton truck will be sent out on an endurance circle tour through the East and Middle West. It will carry a full load of sand bags and will be in charge of Messrs. Giroux and Carlson.

Maps showing the route to be taken will be posted in all of the Little Giant agencies and branches, the progress being traced on them daily in colored pencil. At the conclusion of the trip a booklet, showing the costs and other details of the run, and illustrated from photographs, will be circulated.

Factory Miscellany

FLINT Employing 2,700 More Men—According to an investigation made in the Flint, Mich., automobile and motor car parts plants there were about 2,700 more men employed in these plants July 1, of this year, than on July 1, 1913, and judging from the increasing business there will be more men employed by the end of the year than during any previous year. In January there were about 170 less men employed in the various plants than in January 1913; in February there were about 200 more than last year; in March the increase had reached about 900 men and it has been increasing ever since, until now when about 12,000 to 12,500 men are being employed all told. In most of the factories it is stated that the season is about 60 days ahead of last year's.

Rutherford Plant for Tires—Middleton & Sharpe, Rutherford, N. J., will build a plant for the manufacture of rubber tires.

Bay City Co. Erecting—Stroud, Bridge & Connors, Bay City, Mich., will erect a two-story factory, 90 x 110 feet, for the manufacture of automobile accessories.

Rim Concern Building—The Lookout Bending Co., Chattanooga, Tenn., will erect a plant at Sulphur Springs, Ga., to manufacture automobile wheel rims and spokes.

Addition for Body Co.—The Gustav Schaefer Wagon Co., Cleveland, O., manufacturer of wagons and automobile bodies, will erect a three-story addition, 65 by 70 feet, to its plant.

Walker-Weiss Axle Adds—An addition to cost about $20.000 will be built to the plant of the Walker-Weiss Axle Co. Flint, Mich., whose business has been very good thus far this year.

Auto-Lock Co. Erects—The Common Sense Auto-Lock Co., Ltd., Spokane, Wash., recently incorporated with a capital stock of $1,000,000, by W. H. Purcel, R. B. Weber and others, will soon erect a factory.

To Build Largest Plant in U. S.—The American Aluminum Co. has announced the purchase of a $400,000 strip of land in Edgewater, N. J., as a site for a $2,000,000 plant to be erected in the fall. It will be the largest aluminum manufacturing plant in the United States, it is said, and will employ from 2,000 to 3,000 men.

U. S. Truck in Covington—The United States Motor Truck Co., Covington, Ky., has filed articles of incorporation. It has a capitalization of $250,000. R. C. Stewart and others are the incorporators, and it is understood that the plant of the Stewart Iron Works in Covington will be used temporarily for the manufacturing operations.

Storle's New Engine—The Storle Gas Engine Co., Kewaunee, Wis., is preparing for a large production of internal combustion engines of a new type perfected by O. O. Storle, and to be built both for stationary and movable purposes. The motor has a new valve arrangement concerning which little will be divulged until final patents have been applied for and the production started.

Buys American Welding Equipment—The Western Fixture Co., 573 East Water street, Milwaukee, Wis., a large welding concern, has bought the equipment and stock of the defunct American Welding Co. of Milwaukee and will double the size and capacity of its plant. The Western company is one of the first in the middle west to undertake the modern method of welding.

Johnson Carburetor Organized—The Johnson Carburetor Co. has been organized in Detroit, by C. F. Johnson, expert carbureter engineer of the Cadillac Motor Car Co.; Harry Potter, sales manager of the McCord Mfg. Co., and Rex Johnson, production manager of the Cadillac Motor Car Co. The plant is located at 272 Harper avenue. H. W. Farr is sales manager, with offices in the Union Trust building.

Holihan Co. Moves—The Holihan Mfg. Co. has removed to its new plant on Jefferson avenue, west, and Twenty-first street, Detroit, Mich. This concern which manufactures radiators, hoods, tanks, fenders has been growing exceptionally fast. "We started in business only last January," said President J. A. Holihan, "and we had a force of ten men. Now we have close to 100. We now have three times as much floor space, have added much new machinery and are well equipped to take care of any amount of business."

Will Manufacture Electric Motors—The Marathon Electric Mfg. Co. has been organized at Wausau, Wis., with $150,000 capital to manufacture electric motors, generators, and general electrical equipment of all kinds. Justin Lebovici, until recently electrical engineer for the Westinghouse and Crocker-Wheeler companies, has been appointed general production manager, designer, and chief engineer. E. M. Bischoff, formerly in charge of the manufacturing and sales department of the Crocker-Wheeler company, is secretary, treasurer and general manager. The concern is backed by a number of the largest business men and manufacturers of Wausau and Marathon county. The new forest products laboratory built by the government for research and experimental work in pulpwoods by the forestry division of the department of the interior, has been purchased outright with equipment and will be equipped for electrical manufacture. The laboratory was put on the market because the pulpwood work was finished and the government had no further use for the plant.

The Automobile Calendar

July 25-26	Belgium Grand Prix Road Races.
July-August	French Army Truck Subsidy Trials.
Aug. 1-3	Galveston, Tex., Beach Races.
Aug. 2-9	Grenoble, Automobile Club of France's 6-Day Motorcycle and Cyclecar Reliability Contest in French Alps.
Aug. 16	Le Mans, France, Automobile Club de la Sarthe's Coupé International Light-Car Race, 1 liter, 400 maximum cylinder area, 350-500 kilos weight.
Aug. 17	Le Mans, France, Auto Club de la Sarthe's Grand Prize de France for 4½ liter cars.
Aug. 21-22	Chicago, Ill., Elgin Road Races, Chicago Automobile Club.
Aug. 23	Auvergne, France, Coupé de l'Auto Race.
Aug. 27	Brooklands Track, England; Annual Automobile Race.
Aug.	Denver, Colo., 650-mile Run, Colorado Springs to Salt Lake City.
Aug.	Russia, Road Race, Coupe de l'Empereur, 2,500 miles.
Sept. 6-7	Brescia, Italy, Auto Club of Italy's 4½-liter Grand Prize.
Sept. 6-7-8	Newark, N. J., Cyclecar Reliability Tour to Atlantic City.
Sept. 7-14	Indianapolis, Ind., Automobile Show, Indianapolis Automobile Trade Assn.
Sept. 9	Corona, Cal., Road Race, Corona Auto Assn.
Sept. 10	Portsmouth, Eng., Autumn Conference, Institute of Metals.
Sept. 10-15	Berlin, Germany, German 4½-liter race.
Sept. 15-Oct. 11	New York City, Commercial Tercentenary Celebration.
Sept. 26	Brooklands Track, England, Annual Automobile Race.
Sept. 26-Oct. 6	Berlin, Germany, Automobile Show.
Oct.	Philadelphia, Pa., E. V. A. A. Annual Convention.
Oct. 4	St. Louis, Mo., Automobile Show, Auto Manufacturers' and Dealers' Assn.
Oct. 7-17	New York City Electric Vehicle Show, Grand Central Palace.
Oct. 9-Nov. 2	S. A. E. European Trip.
Oct. 16-26	Paris, France, Automobile Salon.
Oct. 17-24	Pittsburgh, Pa., Automobile Show, Auto Dealers Assn., Inc.
Oct. 19, 20, 21	Philadelphia, Pa., Elec. Veh. Assn's Convention.
Oct. 19-26	Atlanta, Ga., American Road Congress of the American Highway Assn. and the A. A. A.
Oct. 28-31	Milwaukee, Wis., Convention, Northwestern Road Congress, Auditorium.
November	El Paso, Tex., Phoenix Road Race, El Paso Auto Club.
Nov. 6-14	London, England; Olympia Show.
Nov. 8-9	El Paso to Phoenix, Ariz., Automobile Race.
November 8-11	Shreveport, La., Track Meet, Shreveport Auto Club.
November 15	Paris, France, Kerosene Motor Competition.
Jan. 2-9	New York City, Annual Automobile Show, Grand Central Palace.
Jan. 23-30	Chicago, Ill., Automobile Show, First Regiment Armory.

The Week in  the Industry

Motor Men in New Roles

MURPHY Chief Engineer for Franklin—Ralph Murphy has been appointed chief engineer of the H. H. Franklin Mfg. Co., Syracuse, N. Y., manufacturer of the Franklin automobile. He has been for the last 2 years head of the service department. He succeeds Arthur Holmes as chief engineer. Mr. Holmes for the past 6 months has been vice-president and sales manager of the company.

Austin With Grant—Ray Austin, who was formerly connected with the Studebaker Corp., has accepted a position as assistant engineer for the Grant Motor Co., Findlay, O.

Moore Moon Manager—L. B. Moore, formerly district salesman for the Moon Motor Car Co., Cleveland, O., has taken the management of the Sixth City Motor Co., distributor of Moon.

Shoup Oakland Branch Manager—L. S. Shoup, formerly sales manager of the John Deere Plow Co., has been appointed branch manager of the Oakland Motor Co., Indianapolis, Ind.

Higginbottom With Marmon—Herbert Higginbottom formerly with the Ranier and later with the Abbott-Detroit is traveling in the Northwest for the Nordyke & Marmon Co., Indianapolis, Ind.

Brown Goes to New Haven—Frank L. Brown, formerly with the Alvan T. Fuller Co., Boston, Mass., agent for the Packard, is at New Haven where he has charge of the distribution of Stutz cars.

Benson Manager for Partridge Concern—F. G. Benson, identified with the automobile business in New York and New Jersey for the last 9 years, has been appointed wholesale manager of Partridge, Clark and Kerrigan, Inc.

Sitgreaves Heads Mercer Agency—The Trenton Motor Sales Co., Cleveland, O., has been organized and incorporated to succeed the Mercer Auto Sales Co. and handle Mercer cars for that territory. G. L. Sitgreaves is manager.

Duck to Manage Cushion Wheel Co.—George H. Duck, who has been identified with the motor truck industry for several years, has been appointed manager of the Sewell Cushion Wheel Co., New York City, with offices at 1790 Broadway.

Holton Monarch Sales Manager—Hoover Holton, who has formerly been associated with the American Motors Co. and the Empire Automobile Co., Indianapolis, has taken full charge of the sales for the Monarch Motor Car Co., Detroit, Mich.

Kent Leaves Pierce-Arrow—F. C. Kent, general superintendent of the Pierce-Arrow Motor Car Co., Buffalo, N. Y., has severed that connection to become works manager of the Lodge & Shipley Machine Tool Co., Cincinnati, Ohio.

Reed Resigns from Norwalk—W. S. Reed, for 3 years chief engineer of the Norwalk Motor Car Co., Martinsburg, W. Va., has resigned to take a similar position with the Cowles-MacDowel Engineering Co., Chicago, Ill., the change being effective July 15.

Coy Buick Sales Manager—J. B. Coy, Louisville, Ky., for several years district manager for the International Harvester Co., has been appointed sales manager for the Milwaukee, Wis., branch of the Buick Motor Co. M. J. Monson is general manager of the branch house.

MacManus Makes Change—T. F. MacManus, formerly president of the MacManus Advertising Company, Detroit, Mich., which is well known in the automobile trade, has become affiliated with the Dunlap-Ward Advertising Co., also well known in the automobile trade.

Montgomery Heads Detroit Krit—The Krit Motor Car Co., has recently opened a new local branch at 1225 Woodward avenue, Detroit, Mich., under the management of K. R. Montgomery. H. L. Davies, manager of the used car department of the Krit company, will be in charge.

Hood Detroiter Sales Manager—W. C. Hood, one of the veterans in the automobile business, having started as an experimental worker on some of the first steam motor cars in 1898, has been appointed sales manager of the Briggs-Detroiter Co., Detroit, Mich., which makes the Detroiter car in Detroit.

Vedder Studebaker Manager—E. G. Vedder, formerly assistant manager for the Gray Motor Co., distributor in the Twin Cities for the Studebaker car, has been made manager at St. Paul, transferring from the Minneapolis office. P. W. Perlstrom has been transferred from the Minneapolis shop to the St. Paul mechanical department.

Cadillac Agency Reorganized—The Cadillac agency in Boston has been reorganized and a new company incorporated for $100,000 with A. L. Danforth as president, J. James McGregor, treasurer and B. K. Danforth secretary. President Danforth took charge of the agency a few months ago following the retirement of Alfred Measure.

Change in Bosch Officials—A. H. D. Altree, former branch manager at Chicago, has been appointed to the office of vice-president of the Bosch Magneto Co., New York City, and will be located at the main offices of the Bosch company at Nw York. F. D. Norman, previously in charge of the Bosch company's Toronto office, has been appointed branch manager at Chicago.

Penn Resigns—Ralph Penn has resigned as manager of the Milwaukee branch of the Ralph Temple Automobile Co., Chicago, to become Milwaukee representative of the Baker electric. Mr. Temple has taken quarters at 137 Oneida street, the home of the Baker electric for several years. A. H. Esbenshade, who has been agent for the Baker, has retired to devote his entire attention to his other extensive business interests.

DuComb Joins Barthel & Daly—W. C. DuComb. Jr., formerly assistant engineer of the Standard Roller Bearing Co., and engineer of the Royersford Foundry & Machine Co., has become a part of the organization of Barthel & Daly, New York City, sole importers of Schafer ball bearings, and will act in the capacity of mechanical engineer. Mr. DuComb will shortly make an extensive trip through the automobile trade in the interests of Schafer ball bearings.

Oakland Branch Managers Meet—At the annual meeting of branch managers of the Oakland Motor Car Co., Pontiac, Mich., the 1915 models were shown for the first time and were explained to the visitors by chief engineer N. E. Wahlberg. Fred W. Warner, general manager, gave his views on the automobile business in general and explained the company's policy for 1915. It was reported that the company will more than double its output for 1915.

Garage and Dealers' Field

Overland at Pacific Exposition—The Willys-Overland Co., Toledo, O., has made application for 1,500 square feet of space for its automobile exhibit at the Panama-Pacific exposition, San Francisco, 1915.

Prather Building Demountable Rim—Prather Bros., Georgetown, Ky., have leased a building and will equip it with wood and metal working machinery for the manufacture of a demountable automobile wheel.

Reo's New Newark Bldg.—The Reo Motor Car Co., Newark, N. J., has acquired property at 39 William street and will establish a large sales room and repair plant. The repair plant will be equipped for all classes of work. W. E. Dunsenberry is manager.

New J-M Service Station—The H. W. Johns-Mansville Co., New York City, distributor of automobile accessories, announces the opening of a new store and service station at 1,930 Broadway. The former quarters at Broadway and Seventy-sixth street long ago proved inadequate.

Kansas City Dealers Building—Several new buildings for different dealers are under construction in Kansas City, Mo. now. The Hupmobile company is building at 1819 McGee street. The Republic Tire Co. is completing new quarters at 1813 Grand avenue and the Federal Rubber Co. is preparing to move into its new building at 1825 McGee street. The Case company already has occupied new quarters at 2117 Broadway.

Ford Buys Plot in Brooklyn—The Ford Motor Co., Detroit, has completed negotiations for the purchase of a site in Brooklyn, in which wil be erected a six-story brick and steel salesroom and service station.

The company bought the plot at the northwest corner of Sterling place and Bedford avenue, Brooklyn, 44 by 100 feet. Plans were filed for enlarging the Long Island City plant by an eight-story addition, to cost $650,000.

Accessories for the Automobilist

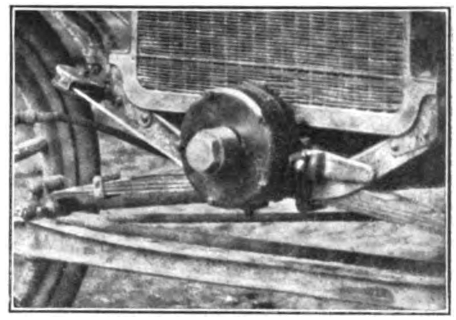


Fig. 3—Mogul starter for cyclecars and automobiles of the smaller type, made by Mogul Starter Co., Chicago, Ill.

POSITIVE Steam Tube Vulcanizer—The Positive Supply Co., Davenport, Iowa, maker of portable steam vulcanizers and kerosene garage heaters, has recently brought out a small steam tube vulcanizer for use in private garages and small repair shops, Fig. 1.

The new Positive is the only vulcanizer, it is said, made expressly for repairing inner tubes and uses the steam principle of vulcanizing. It is a complete steam vulcanizing plant put up in small box, so it can be carried in a tool kit of a car. The Positive consists of a metal body, with a compartment for water and another for fuel. The water compartment is between the inner tube and the flame, where it equalizes the heat generated. It vulcanizes a patch that actually becomes a part of the tube, without danger of burning or scorching.

It is so constructed that it may be firmly mounted on any work bench or post and thus avoiding all tendency for damaging the tube, as it cannot upset. To vulcanize a repair, the repair rubber is put on the tube and the vulcanizer clamped on. The proper amount of gasoline and water is placed on the vulcanizer and ignited. No further attention is required. The vulcanizer weighs 30 pounds and will vulcanize a surface of 12 square inches in one setting and larger ones by resetting. It will repair automobile, cyclecar, motorcycle and bicycle tubes.

The new Positive lists for $1.50 and is sold under a money back guarantee of satisfaction.

Fuel Economizer—Acting on the idea that hot, moist air will increase the power of the motor, the J. H. Forsythe, Alliance, O., is making a device, Fig. 2, that takes warm moist air from the upper part of the radiator. Referring to Fig. 2. The suction of the engine draws it through tube A to the inlet of the economizer, thence through baffle plates where it comes into contact with the hot water pipes and thence through a thermostatic valve which admits air at a temperature somewhere between 105 and 175 degrees, thence through a two-way valve to the intake manifold of the engine.

Lesoyl Lubricating Compound—A lubricant, in the form of a semi-liquid graphite compound, has been brought out by the Lumen Bearing Co., Buffalo, N. Y., under the name of Lesoyl. This substance is designed to be mixed with

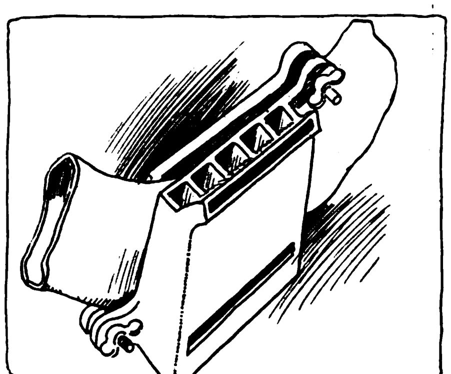

Fig. 1—Positive steam tube vulcanizer for use in private garages and small repair shops made by Positive Supply Co., Davenport, Ia.

lubricating oil or grease in order to perpetually suspend the graphite and lubricate the wearing surfaces in the same way apparently as is accomplished by the use of deflocculated graphite. It is stated by the maker that better lubrication is obtained than by the use of oil alone, owing to the fact that the graphite is carried to the bearing surfaces and the oil film remains unbroken. A can containing the proper amount of Lesoyl to be mixed with 5 gallons of oil sells for $1.

Folding Sub-Car—The "Get out and get under" fever has evidently been making its way to Ohio, where the Auto Folding Sub-Car Co., at Zanesville has announced the Folding Sub-Car, a device which permits of making easy repairs and adjustments underneath a motor car. The feature of this device is that it may be folded so as to be but 18 inches long and hence may be carried in the car at all times. This car sells for $5 and should be especially valuable to those contemplating long tours.

Mogul Starter—A starter, Fig 3, that is operated by a pedal is now manufactured by the Mogul Starter Co., 1323 Michigan avenue, Chicago, Ill., for cyclecars and automobiles such as the Ford, Krit, Roe, Overland, Maxwell, Mitchell, The price of the automobile starter complete with primer is $30, and for cyclecars it is $12 to $15 without equipment.

Demountable Hub for Ford Wheels—The Allen Machine Co., Detroit, Mich., is manufacturing a special hub, Fig. 4,

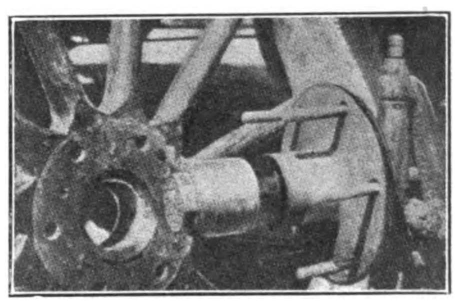

Fig. 4—Allen demountable hub for Fords

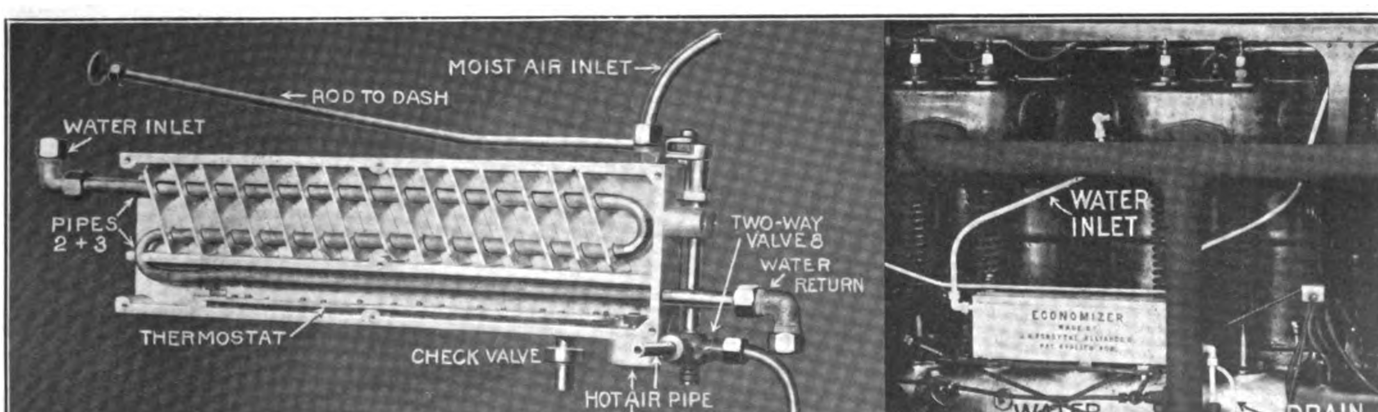

Fig. 2—Left—Cross-section through the Forsythe fuel economizer which acts on the idea that warm, moist air will increase motor power. Right—The economizer applied to a motor

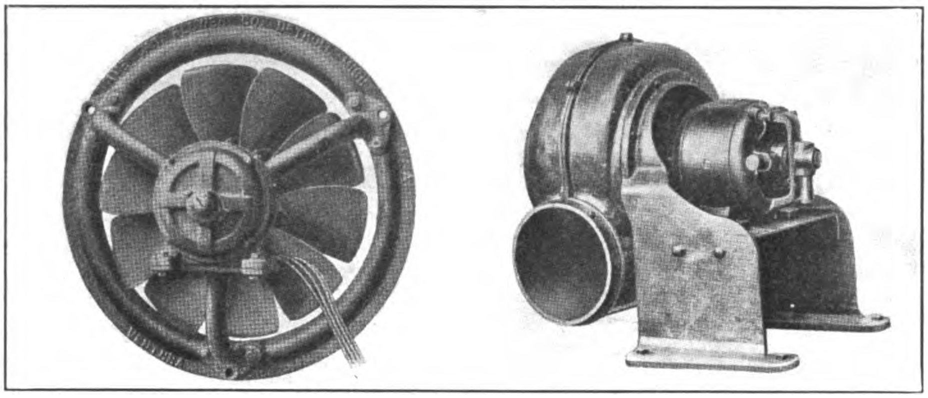

Fig. 5—Two new types of Westinghouse small motor-driven fans, the Ventura at the left and the Sirocco Blower at the right. Made by the Westinghouse Electric and Mfg. Co., East Pittsburgh, Pa.

for attachment to Ford wheels, that allows the wheels to be demounted. It is furnished in a set of five, which includes an extra wheel and the necessary parts for making all the wheels demountable. To remove a wheel fitted with the Allen device it is necessary only to unscrew six cap nuts, when the wheel slides off easily; the replacement is a reversal of this process and there are no tight parts to make the operation difficult.

The essential feature of the Allen appliance is the metal ring located back of the inside hub flange and carrying six bolts which pass through the hub of the wheel. These bolts take the place of the ordinary hub bolts, which have their nuts on the inside. The unscrewing of the special nuts permits the wheel to slide off leaving the bolts in place; the metal hub with its ball bearings is not disturbed.

Westinghouse Fans—An extensive line of small motor-driven fans is manufactured by the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa. These outfits are compact, quiet running, clean and efficient, it is stated. They are made in two types to suit all conditions of service, one the Ventura Fan and the other the Sirocco Blower, Fig. 5. Both types can be supplied from direct or alternating current circuits and all can be operated from electric lighting circuits. The motors are specially designed for the service and are characterized by great reliability, it being claimed that they will operate for years with practically no attention, except occasional oiling.

Monarch Headlight Dimmer—The city of Chicago has made it imperative that every motor vehicle be equipped with headlights whose light is not blinding and only those lamps which have been inspected are permitted to be used. The manufacturers of such devices offer the glare removers for inspection and upon the presentation of a certificate the manufacture and sale is authorized. A certified dimmer is being made by the Distributors and Manufacturers Co. and is called the Monarch. It consists of a circular piece of celluloid composition, bound with a metal rim from which three metal flexible arms protrude. These arms, shown in Fig. 6, are designed to be clamped to the lamp rim. The celluloid disk, which is finished on one side and dull on the other, has a white spot in the center varying in size with the size of the lamp equipment. This white spot is made by the use of white printer's ink. Aside from its being an effective glare remover, the Monarch has the feature of being applicable to either inside or outside of the lamp lens, and it

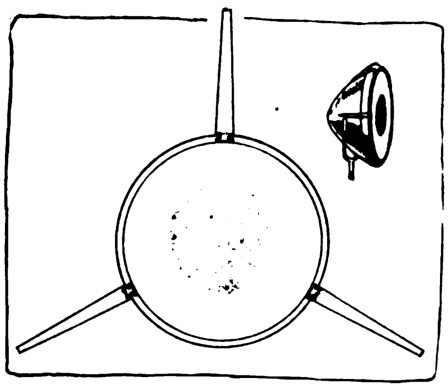

Fig. 6—Monarch headlight dimmer of celluloid composition made by the Distributors and Manufacturers' Co., Chicago, Ill.

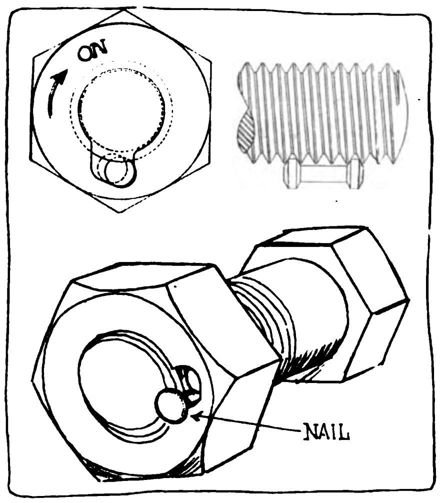

Fig. 7—Absolute lock-nut made by the American Lock-Nut Co., Chicago, Ill.

appears it is better adapted for the inside where it cannot be interfered with. An added feature is its price, a pair selling for $2.

Absolute Lock-Nut—By the use of a slotted nut and a roller fitted as shown in Fig. 7, the American Lock-Nut Co., Pullman Station, Chicago, Ill., claims to have a lock nut that will hold under all conditions of service, the locking action being obtained by means of the roller which fits into the threads of the bolt and also rolls in the recess cut in the nut. The nut is continuously and automatically locked against backward motion because such motion only wedges the pin tighter into the threads of the lock.

To remove the nut from the bolt, a nail or brad of sufficient size is inserted between the wall of the shallow portion of the recess and the locking pin permitting the nut to be easily removed.

Twentieth Century Steam Curing Bag—A device, Fig. 8, that will enable the repairman to cure the inside of a tire just as well and as easily as the outside and thus makes it possible to do both inside and outside at the same time is made by the K & W Rubber Co., 1545 Broadway, Denver, Col. It is called a steam curing bag and consists of a flexible cylindrical bag that can be inserted in the shoe and as it is flexible it takes the shape of the interior automatically. An inlet and outlet steam connection are provided. All parts are made of metal except the curing surface.

It is stated that this device saves time and doubles the capacity for repair work, as it eliminates the changing of moulds.

The prices vary from $20 for the 2.5-inch size to $35 for the 5.5-inch size.

Keyless Auto Lock—The Factory Sales Co., Cleveland, O., is putting on the market an ignition lock, Fig. 9, that is opened by a combination the same as is a safe. This feature does away with the necessity for a key and removes the possibility of not being able to start the car because the key is in another suit of clothes or lost. The device is composed of metal throughout and is said to be indestructible. It sells for $7. It is equipped with a small electric light so that the dial can be seen at night. Two types of locks are made: one for cars that can be locked by breaking the low-tension circuit and another for cars that cannot be locked by this method. In this case the high-tension circuit is locked. The former type can be used on all ignition systems except Bosch, Mea and Eisemann magnetos, which require the latter.

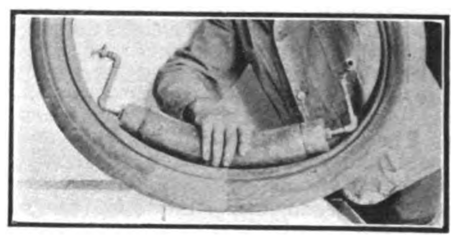

Fig. 8—Twentieth Century Steam Curing Bag for curing the inside of a tire as well as the outside, made by the K. & W. Rubber Co., Denver, Col.

Vol. XXXI New York—Thursday, July 30, 1914—Chicago No. 5

The Automobile

How Weight Distribution Affects Skidding

Heavy Rear Less Liable To Skid But More Dangerous—Braking and Acceleration Must Be Gradual

By the Late E. P. Batzell

THE most desirable distribution of weight in an automobile is an interesting problem. Much guessing could be attached to it and the only way to obtain much valuable information would be to appeal to all interested for their views.

Although it looks simple at first, the problem involved cannot be disposed of lightly, for instance, by stating the requirement of a center of gravity, located above the ground and near it. The advantages connected with proper weight distribution are far too great for that, because here is concerned not merely the running of the car on the road, but the ability of the car to keep to its given and desired direction.

Little Attention for Weight

As a general rule the designer brings out a car with insufficient attention given to the matter of weight distribution, locating parts and accessories according to his judgment and the space available. Then the car is tried on the road and sometimes it will be satisfactory, and in other instances it might have many defects, such as easy skidding, a tendency to leave the road at certain speed, hard steering, etc. Considering that these defects can be largely due to incorrect weight distribution, this at once brings into prominence the problem mentioned. The fact that there are cars which perform very well and others which leave many things to be desired in this respect proves that a proper handling and analysis of the situation might enable everybody to enjoy the stable type of automobile.

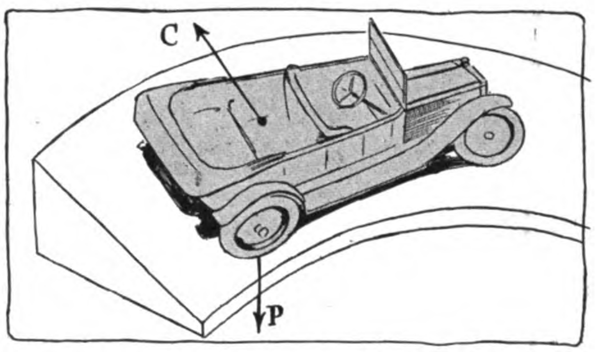

Fig. 1—In turning to the right on a road surface which is inclined so that the inner rear wheel receives a greater part of the load, P, there will be no danger of skidding in accelerating, despite the uneven traction on the two rear wheels, because the centrifugal force, C, tends to equalize the load on the wheels

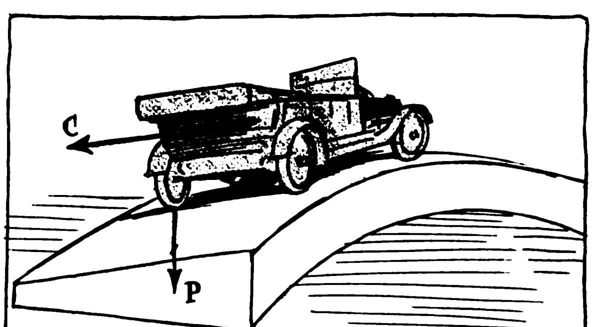

Fig. 2—But in turning where the outer wheel is lower than the inner the situation is extremely unstable, because the centrifugal force, C, in addition to the force of gravity, assists outward skidding

In view of the fact that the biggest value of the discussion is attached to the performance of cars when running no reference will be made to their stability when standing.

For the sake of simplicity it is assumed that the center of gravity in various cases is located in the middle plane of the automobile, that is, the vertical plane which passes through the middle of the front and rear axles when the car stands on level ground. To simplify matters further no reference will be made to the overturning of cars when running, this being governed by conditions which are obviously more or less understood. *Chief interest is concentrated on the skidding of the car.*

This phenomenon is to be con-

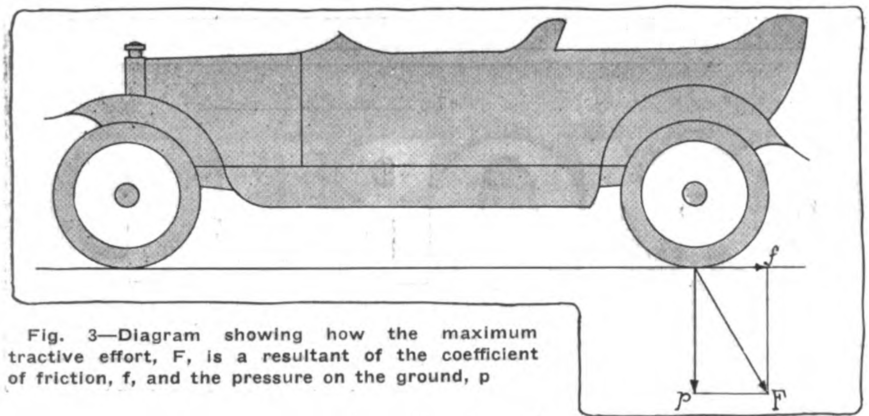

Fig. 3—Diagram showing how the maximum tractive effort, F, is a resultant of the coefficient of friction, f, and the pressure on the ground, p

sidered separately for a straight direction of travel, for passing on curves and for level and sidewise inclined roads.

Skidding Defined

The term skidding as used here is generally too well understood to require explanation. Let it be said that it refers to that motion of a vehicle when the center of gravity of the latter ceases to follow the direction imposed by the steering apparatus.

The skidding can take place at all wheels at once, or separately at the front or the rear wheels or one of either. The driving force exerted upon the vehicle and the application of brakes influence the rate of skidding at the front and at the rear end, therefore, the most favorable weight distribution in that connection. Supposing a driving wheel, Fig. 3, is exerting a pressure upon the ground. With a co-efficient of friction f between the wheel and the ground, the maximum tractive effort to be transmitted by this wheel is $F = p \times f$. Also if there is a force present, which acts sidewise upon this wheel, the latter will retain its adhesion to the ground as long as the supplied tractive effort in connection with the sidewise force result in a combination effort which is not more than $F = p \times f$. When the latter is reached, the wheel slips against the ground, in other words, it loses its grip upon the latter, and has a tendency to move sidewise under the influence of these acting forces.

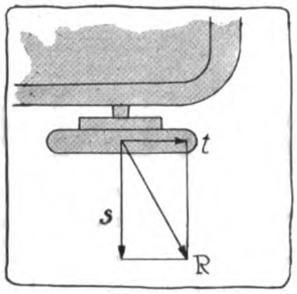

Fig. 4—Plan of the rear wheel in Fig. 3, showing the resultant, R, of the tractive force and a side force, s. It is this force, R, which causes skidding as soon as the wheel loses its hold on the ground

Fig. 4 represents the plan view upon the wheel of Fig. 3. With any given tractive effort t there will be found existing such a sidewise effort s which will combine with the former into a resultant force r equal to $F = p \times f$, consequently forcing the wheel to skid. From Fig. 4 it is seen that with increasing tractive force t less sidewise strain is necessary to bring the wheel into skidding. No doubt readers will have noticed this occurrence in practice, for instance, when leaving a level road for a hill. Although more weight is thrown upon the rear axle, in going up grade, this increase of load carried is not in proportion to the increased traction effort, whereas if the car is going as directed on the level it starts to skid on the up grade if conditions favor the origin of side efforts upon the rear wheels.

Applying Brakes Hard Is Dangerous

Acceleration of the motor also tends to throw an added weight upon the rear axle which increases the tractive effort practically in proportion to the weight carried. In this instance, the skidding is not made easier because the sidewise strain s which could cause it, must increase in the same proportion as the weight and tractive effort forces. On the contrary, the application of the brakes will have the opposite result, favoring the easier skidding under certain given side strains.

The truth of the above is retained only as long as the wheels have full adhesion to the ground until the skidding starts under the influence of acceleration or braking. The conditions are somewhat different when one accelerates or applies the brakes after the skidding has already taken place.

Heavy Rear Resists Skidding

The foregoing, which refers to the origination of skidding at the driving wheels indicates that there is less chance of such skidding with a greater load near the driving axle, the rear axle. This is easily confirmed by practical experience when driving a light car. One will have noticed that such a car without passengers in the rear easily develops the tendency to jump and slide at the rear end upon a more or less uneven road, when going at a high rate of speed. At the same time the well loaded front, namely, the steering wheels, permit controlling the direction of the car without difficulty, even with the sliding rear end.

On the other hand, the same car with passengers on the rear keeps to the road much better and steadier but in event of its going off from the desired direction the righting of it is much more difficult.

Weight at Rear Has Many Disadvantages

The concentration of the load at the rear end has also other disadvantages connected with it besides the steering. Its greatest disadvantage lies in the behavior of the car once it started to skid because the heavy rear end has a greater tendency to continue in its skidding motion overpowering the influence of the front end steering. During a skid one must consider that the skidding wheels have practically no adhesion to the ground, therefore, as will be seen from Fig. 6, during a skid, the car, with its weight concentrated at the rear end on the point R tends to turn round its front axle with an effort equal to the inertia of its mass acting upon a lever of the length a. Another car with its weight concentrated nearer to its middle generally will have a smaller acting effort of the inertia of its mass because its skidding motion at this new center of gravity M is less rapid than at the point R. Besides this smaller effort acts upon a shorter leverage b, which connected with better traction at the front wheels permits straightening of the car from the skid much easier than in the first case—with a heavy rear end. Notice the difference in efforts required, when skidding on a wet asphalt pavement with or without passengers and with smooth tire equipment.

Heavy Front Awkward But Less Dangerous

The concentration of the weight very near to the front end of the car is undesirable, also when considered in connection with a front skid with the natures of the rear and the front skidding being mostly different, there is less danger with a heavy front than with a heavy rear end, whereas the rear skid forces the car from its assumed direction, the front skid generally covers that case when the car continues to travel in a previously acquired direction even when the steering wheels are turned to the other end. Here the steering effort of the wheels, which is not the same as their traction, multiplied by their distance from the rear axle, forms a steering moment acting upon the car which is not sufficient to direct the motion of the latter mass from its assured way. The concentration of the mass further forward increases the leverage upon which it tends to concentrate the steering movement.

On the other hand, the forward location of the center of gravity giving greater weight upon the front wheels also increases their tendency of adhesion to the ground, namely, their steering movement, and it generally reduces the chances for a dangerous front skid.

Inertia in Skidding

Acceleration or the application of brakes during a front skid are more or less inert in their efforts and are not influenced by the concentration of the vehicle weight in any point in the middle plane of the automobile. Their action produces inertia forces acting in the direction of the maintained vehicle motion. The increasing tendency of the vehicle to adhere to this wrong direction during the braking could be offset by the simultaneously increasing load upon the front axle, and naturally on the front wheels. *In some cases this braking can even stop the skid by increasing the load upon the steering wheels to an extent when they will regain their grip on the ground.* During acceleration the inertia of the mass gives a more undesirable effect by reducing the load carried by the steering wheels. In fact, one can start a front skid by acceleration on unfavorable conditions when the wheels otherwise still retain their adhesion to the ground.

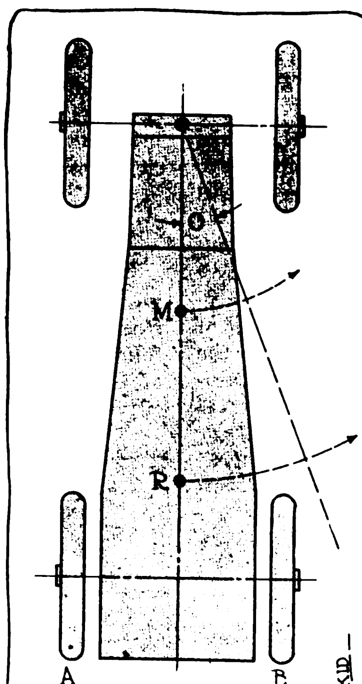
In the event of a complete rear skid both the acceleration and braking produce markedly bad effects which at the same time are further impaired by the weight near the rear end. When both rear wheels lose traction this is a complete rear skid. Then, as a matter of fact, no acceleration can be produced in the full sense of the word. But the swifter rotation of these wheels, or their faster skidding relatively to the ground, reduces the already small co-efficient of friction between the two. *Thus chances are reduced to stop the slipping.* When the rear skid is caused by one of the rear wheels starting to slip, the car assumes a direction of motion at its rear end, such that the slipping wheel travels inwards following the motion of the other wheel, which moves outward. If in Fig. 5 the slipping wheel is A and the driving wheel is B, the accelerated motion on the latter increases the skid for obvious reasons, the skid being originated through the difference in the traction of the two wheels B and A. The concentration of weight near the rear axle in this case is of some slight advantage, because it takes a greater amount of work to pivot the car round the front axle on any given angle O, the displacement of the concentrated weight being greater with the increase of its distance from that latter axle. *A slight application of the rear brakes might help to righten the car, as long as the brakes do not lock. But the application of brakes as soon as one wheel begins to slip is apt to cause a worse skid than when the car is left entirely free with motor out as well.*

THE APPLICATION OF BRAKES DURING A COMPLETE REAR SKID IS VERY DANGEROUS. It cannot produce any great effort at the rear wheels, because the latter have very little adhesion then, but whatever effort is produced by the remaining slight friction adds to the force of inertia created by the skid for no advantage to the car. It tends to throw the weight of the car forward opposite to the direction as the braking acts upon the rear wheels. *Thus the rear end is materially lightened, its traction decreased and it is left more freely to skid in the started direction.* The concentration of weight at the rear is less desirable here because it retains the greater tendency to continue a skid with brakes applied, over that shown by cars with the center of gravity further ahead. Every day's practice confirms the above as well as the other cited examples.

The rather harmful influence of braking with both wheels slipping is easily experienced, also the resulting greater skid with a heavier load at the rear end. These items are particularly noticeable when the road conditions are more or less favorable for causing the skidding, for instance, when the car is on a sidewise incline like the street surface dropping towards the curb.

Rear Skids More Easily Than Front on Curves

The passing of a car on a curve gives another instance when the question of weight concentration could offer much material for discussion. With reference to Fig. 6 the load when concentrated at the rear exerts a centrifugal force acting sidewise upon the car and applied on a greater leverage to the pivoting point at the front axle than would be the case were the load placed nearer to the front. The rear end generally shows a greater tendency to skid on a curve than the front. That is explained by the discussion referring to Fig. 4, when it was shown that a smaller sidewise effort will cause a skid when the traction effort of the wheel is increased. The front wheels, having no tractive effort, can withstand a greater sidewise strain of the centrifugal force on curves than the driving wheels stand. *That is why it would make a more stable car for passing on curves to have the load concentrated amidship or slightly ahead of it.* Other things being equal, the practice when the load is decreased on the rear axle, the actual limit of the latter tractive effort will be reduced



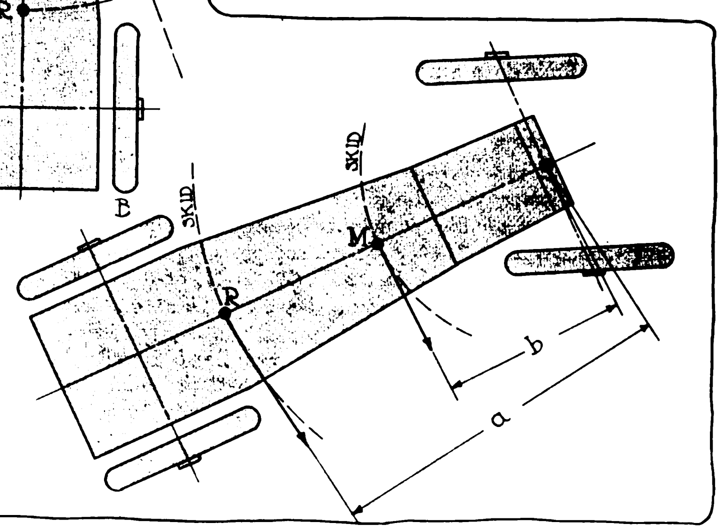


Fig. 5—Above—Diagram showing how a skid started through a slipping wheel, A, is increased through the accelerated motion of the other wheel, B. The rapidity of the skid depends largely on the position of the center of gravity, R or M

Fig. 6—Below—During a skid, when the wheels can be considered to have no adhesion to the ground, the car, with its weight concentrated at R, tends to turn around the front axle with an effort equal to the inertia of its mass acting on a lever of the length, a. With a more forward position of the center of gravity, M, the skidding action is correspondingly less rapid through the lessened leverage, b

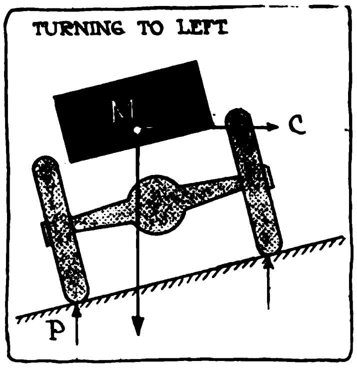

Fig. 7—Showing how the loss of traction on the raised outer wheel in turning and the consequent tendency to skid is counteracted by the centrifugal action of the mass M acting in an outward direction

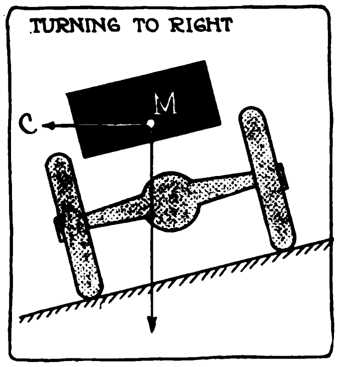

Fig. 8—In turning to the right, however, on the same slope, the tendency to skid is much increased since the centrifugal force, C, is assisting gravity to reduce the adhesion of the inner raised wheel

also, making a proportionally easy skidding car on account of the reduced grip of the wheels to the ground. The weight distribution apparently would become noticeable in its bad effects only when the wheels lose their adhesion to the ground at the time of passing curves.

THE CONCENTRATION OF WEIGHT IN FRONT WOULD BE MORE DANGEROUS FOR A FRONT SKID AND THE CONCENTRATION AT THE REAR END WOULD BE MORE LIKELY TO CAUSE A REAR SKID, WHICH OCCURS MORE OFTEN.

When passing a curve with a simultaneously sidewise road inclination the driver is required to act differently to preserve the stability of the car, whether the inner or outer wheels are on the up grade. *With the outer wheels higher than the inner ones, acceleration just before striking the incline increases the stability and braking tends to pull the car inward.* It is clear from Fig. 7 that on this incline the left wheel receives a greater part P of the load M, hence the addition of a greater centrifugal force C to equalize the loads upon the wheels. *The greater traction on the inner wheel when accelerating cannot cause a skid because its action is directed against that of the centrifugal force, but the skid would have to be expected when the car is traveling in a straight line. Here the inner rear wheels would slide down when accelerating.*

When braking on a curve or on a straight stretch in both cases a front skid can occur.

Centrifugal Force a Factor on Curves

The situation represented in Fig. 8 when the outer wheel on a curve is lower than the inner is extremely unstable, the centrifugal force of the vehicle assisting its skidding outwardly together with the action of the gravity force. *It is best to avoid that situation or apply the brakes before reaching it.* In any event, the braking, even when on this curve, is advantageous, the action being opposite to the centrifugal force. In all cases, a more or less even load distribution would be best because once a skid is started the weight concentration in the rear offers greater difficulties to the steadying of the vehicle.

Further illustration of the two actions referred to above is given in Figs. 1 and 2.

Center of Gravity Ahead of Rear Axle

When concentrating much load at the rear end one has to be very careful to retain the center of gravity more or less ahead of the rear axle, which is absolutely essential for proper stability. The limit which the center of gravity may occupy will be largely determined considering the vehicle upon a grade: Referring to Fig. 9, where C represents the location of the center of gravity, there will exist an angle A with the horizontal when practically no load will be carried on the front end of the car, or steering wheels. A steeper grade with an angle B will, in fact, cause the lifting of the front end of the car from the ground *because the line of gravity action intersects the ground behind the rear wheels at a point* M.

The danger of such conditions is obvious. To prevent them one can build a car of longer wheelbase and with a lower center of gravity the latter has to be close to the rear end. However, it would be preferable at the same time to concentrate the weight more amidship. One must keep in mind that even if the static treatment of the problem shows the line of gravity action intersecting the ground well ahead of the rear axle under assumed extremes upon a grade there remain the forces of inertia when accelerating and the force of wind resistance, which form another component adding weight to the rear and tending to lift the front end.

Goodrich Pay Car Has Safety Bulletin

AKRON, O., July 27—A new device in the field of big manufacturing has been brought out by the B. F. Goodrich Co., Akron, O. It consists of a safety bulletin attached to each pay record card. The pay record card is designed to help the employee keep track of the number of hours he has worked each day, the amount of piece work he has finished and the daily earnings that result.

In addition, however, the card carries a safety talk, touching on a different topic each issue and a new card is published every half month. One safety bulletin tells how to care for a certain ailment, the next what to do to prevent infection of wounds and a third will give advice on the efficiency and possibility of increasing production on piece work.

Electric Vehicle Show October 7-17

NEW YORK CITY, July 27—The Electric Vehicle Show will he held in Grand Central Palace, this city October 7 to 17, starting on a Wednesday evening and closing on the second following Saturday night. The show is under the direction of Charles Parker, care of the New York Edison Co., this city.

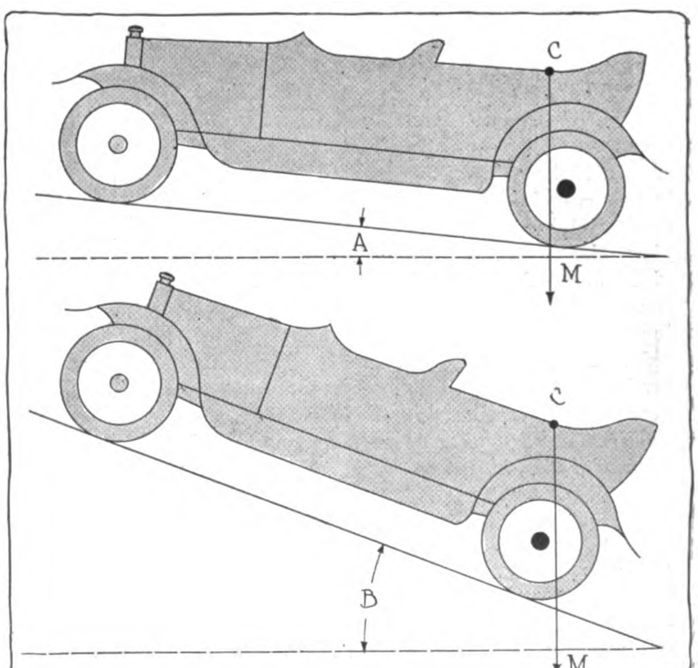

Fig. 9—Diagrams bringing out the necessity of keeping the center of gravity in front of the rear axle. On an incline the effect is equivalent to bringing this point further back

N. A. C. of C. in Summer Session

NEW YORK CITY, July 24—At the business meeting of the directors held at Christmas Cove, Me., on July 21, Dodge Bros., manufacturers of automobiles, in Detroit, were admitted to membership in the National Automobile Chamber of Commerce.

A Truck Convention

The directors endorsed the plan of the Commercial Vehicle Committee for a convention of commercial vehicle interests to be held some time in the fall, the date and place to be selected at the September meeting of the Chamber.

Besides routine matters there were interesting reports from committees on patents, traffic, good roads, legislation and shows. The members were the guests of Samuel A. Miles.

President Charles Clifton presided, while the others in attendance included: S. D. Waldon (Packard); Wm. E. Metzger (Argo); Albert L. Pope (Pope); H. H. Rice (Waverley); Wilfred C. Leland (Cadillac); Roy D. Chapin (Hudson); L. H. Kittredge (Peerless); C. C. Hanch (Marmon); Col. George Pope, Treasurer; S. A. Miles; Alfred Reeves, General Manager; Charles Thaddeus Terry, Counsel; and by invitation, Thomas Henderson (Winton).

Sports a Feature

Keen competition in outdoor sports by leading automobile manufacturers who combined business and pleasure, was a feature of the meeting.

There were three days of the house party, with the directors' meeting held on Tuesday, July 21.

Everyone participated in the sports, there being a tie between the Blues and the Grays, with 20 points each, necessitating a run off at the meeting next summer.

The clam bake in full swing at Christmas Cove

Col. Pope demolishing clams at the clam bake on S. A. Miles' estate

Chas. Thaddeus Terry, counsel, at ease on the rocks of Christmas Cove, Me.

By a score of 6 to 2 the Blues captured the baseball games, being credited with 5 points; the pool and billiard contest, by 150 to 143, taking 10 points and a victory in the water sports netting 5 points.

Clam Bake Great Success

The Grays scored first in the clay pigeon shoot by 27 to 26, receiving 10 points; their team caught the greatest number of fish—104 to 67, for 5 points, while they were credited 3 points for second place in the water sports and 2 points for jumping the bar. The clam bake was held on Sunday and fishing contest and fish fry on Monday.

The manufacturers assembled at Portland last Saturday, going to Bath in motor cars and from there to Christmas Cove by boat.

Left—The party of the National Automobile Chamber of Commerce at S. A. Miles' estate. Top row—Nickerson, Sweet, Garden, Thompson, Post, Reeves, Kittredge and Rice. Middle—Hanch, Wetzel, Budlong, Col. Clifton, Swetland, Edwards, A. L. Pope, Billings and Metzger. Lower—Mrs. Margaret Pratt, S. A. Miles, Henderson, Leland, Col. Pope and Mrs. S. A. Miles. Right—Miles and Waldon consuming lobster, etc.

Springless Valves Are Latest Racing Development

Positively Operated Types Will Probably Not Be Confined to Racing Cars—Were a Success in French Grand Prix for 1914

PARIS, July 17—Multiple overhead valves, front wheel brakes and positive operation of valves on both opening and closing movements constituted the mechanical novelties of the cars taking part in this year's French Grand Prix and intended for the other European road races of the season.

Valves Success in Race

Although positively-operated valves were not found on the winning machine, they, nevertheless, constituted the greatest technical development in connection with the race, and gave promise of an extended application in the near future. Two makes of car used this type of valve arrangement: Delage and Th. Schneider. The valve system was not at fault in the failure of these two makers to win the race.

The Th. Schneider motors were designed and built by G. Michaux, an independent automobile engineer, who was responsible for the rise and success of Peugeot in the racing field. Peugeot first entered racing with single-cylinder, long-stroke motors, developing to twins, and then to fours. It was with these machines produced by Michaux that Boillot and Goux gained the experience which enabled the former to win the Grand Prix 2 years in succession.

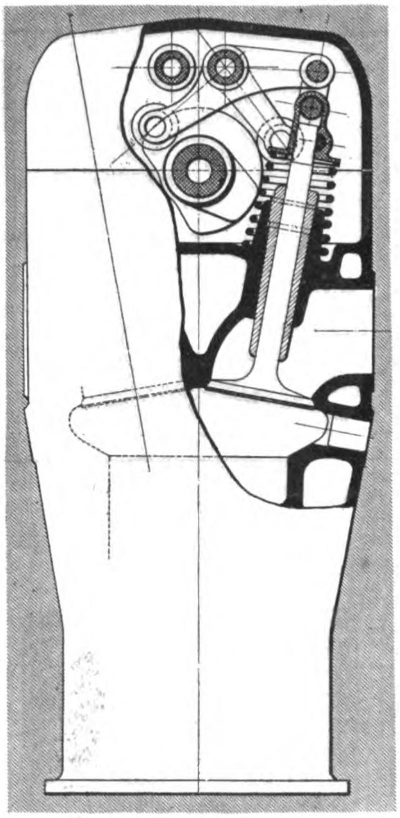

Fig. 1—Section through cylinder head of Schneider motor, showing overhead cam and positive operation of valves. Spring shown is a precaution only

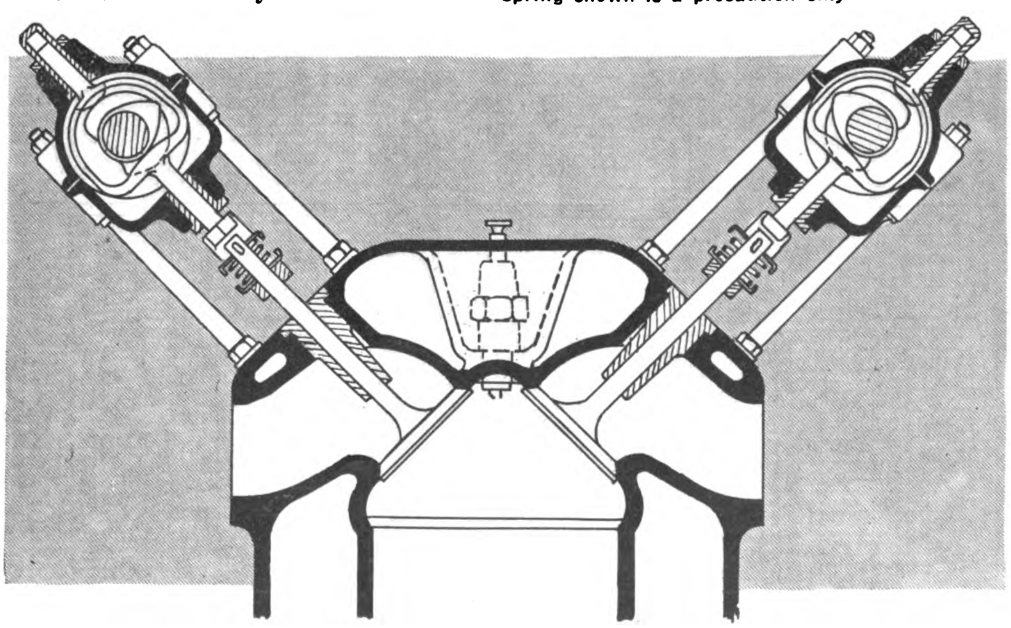
Since severing his connection with Peugeot, Michaux has devoted considerable time to the development of the high-speed motor with positively-operated valves. He has secured patents on the detail construction of this valve gear, and evidence that the device is not likely to be confined to racing cars is to be found in the fact that a leading French firm never having taken part in a road race has secured an option on the purchase of this patent.

Cam Opens and Closes

The positive-valve motor differs from the others by having no necessity for valve springs, a cam not only assuring the opening of the valve but causing its return to the valve seat. In this respect it is similar to the sleeve-valve motor, where the uncovering of the ports is positively assured.

Claims made for this type of valve mechanism are a higher number of revolutions, a greatly increased factor of safety and higher power. With the spring-controlled, single-cam valve, a point is reached when the spring is incapable of seating the valve before the cam has again begun its opening movement. Light valves and strong springs have made it possible to extend the limits considerably, but the valve still remains the limiting factor in



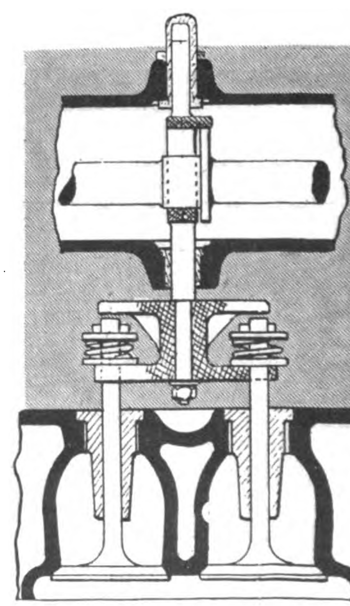


Fig. 2—Arrangement of the springless inclined valves in the Delage, which has two overhead camshafts and sixteen valves.
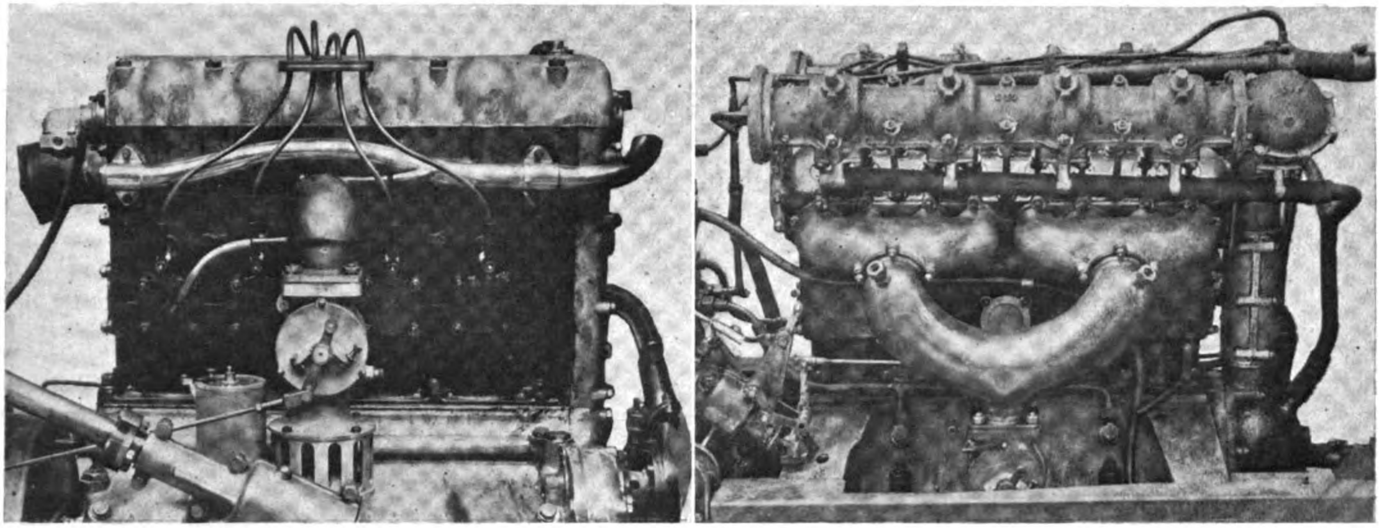
Fig. 3—Showing how each cam operates a pair of valves on the Delage



Figs. 4 and 5—Left, intake side of Schneider racing motor used in the Grand Prix, showing arrangement of overhead camshaft. Right, intake side of Delage motor, showing the two overhead inclosed camshafts

the speed of the motor. With the positively-operated valve it is no longer the valve which limits the speed of the motor.

The No-Spring Scheme

The Michaux arrangement is shown in Fig. 1. There are two valves per cylinder inclined at 10 degrees from the vertical. With a cylinder diameter of 94 millimeters, the valve diameter is 60 millimeters. The valve stems are of big diameter. Owing to positive control there is no necessity to lighten this part in an unusual degree. With such a diameter valve stem breakage is not to be feared.

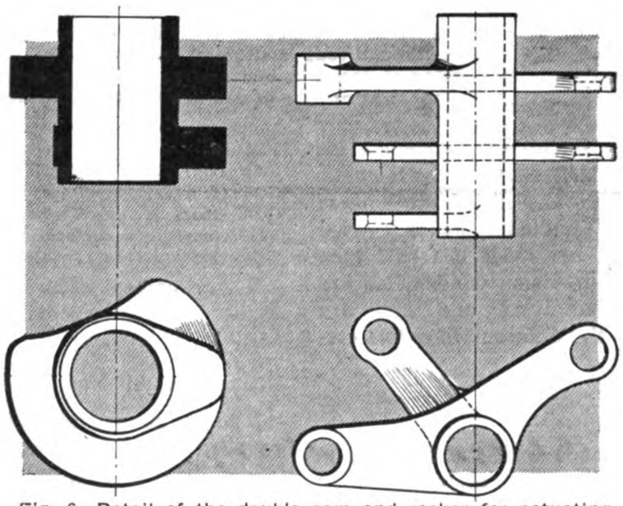


Fig. 6—Detail of the double cam and rocker for actuating the Schneider valves

A single overhead camshaft has eight pairs of cams; these are shown in detail. Also for each valve there is a three-arm rocker, one arm of which is positively connected to the stem of the valve, and the two others are in contact respectively with the opening and the closing cams. A short connecting link is screwed on the end of the valve stem and locked in position, the other end being attached to the rocker arm. This allows adjustment to be made between the valve and the rocker.

Rocker Follows Cam Profiles

One cam and one rocker arm assure the opening of the valve and the corresponding rocker and cam assure its closing. The closing cam has exactly the opposite profile to that of the opening cam. Thus, considering the opening cam as having a convex profile, the closing cam has the corresponding concave profile. Thus the rocker constantly follows the profiles of the cams; there is no moment when it is left free to be operated on by a valve spring.

It will be noticed, however, that a light valve spring is shown in the drawing. This is provided to give a final seating to the valve after it has been closed by the cam. As proof that it is not necessary for valve closing, it may be mentioned that on Champoiseau's car, which finished ninth, one of these springs broke and worked up around the connecting link, where it was entirely inoperative. The breakage was not discovered until 3 days after the race, when the motor was entirely dismounted for a detail examination.

The whole of the valve mechanism is contained within an overhead aluminum cover, and every part is lubricated, the return of the oil being by way of the timing gears at the front to the basechamber.

The camshaft is hollow and is carried in four ball bearings—one at the rear, one in the center and one on each side of the camshaft pinion. The two shafts carrying the two sets of rocker arms are also hollow, and oil grooves are bored in the rockers themselves, so that lubricant is delivered direct to the rollers. There is no valve cage, and the bronze guide for the valve stem is of slightly taper section and is screwed in position.

Owing to the absence of suitable appliance for making brake tests at 3,000 r.p.m. and more, it has not been possible to get comparative data on the power developed from the motors run in the Grand Prix and those of equal dimensions with spring-controlled valves. It is claimed, however, that the power curve will show a much more steady rise than that of a spring-valve motor and will continue rising where the latter begins to fall off.

Apart from the valve arrangement, this motor is interesting by reason of the use of roller bearings for the crankshaft. These bearings are of the R. B. F. make and have been used for crankshafts the first time this year. By reason of their use it has been possible to get the shortest crankshaft of any motor in the Grand Prix, and also to employ a single-piece crankshaft. With ball bearings the shafts were all of the built-up type. The only difficulty in connection with this bearing was the placing of the central one.

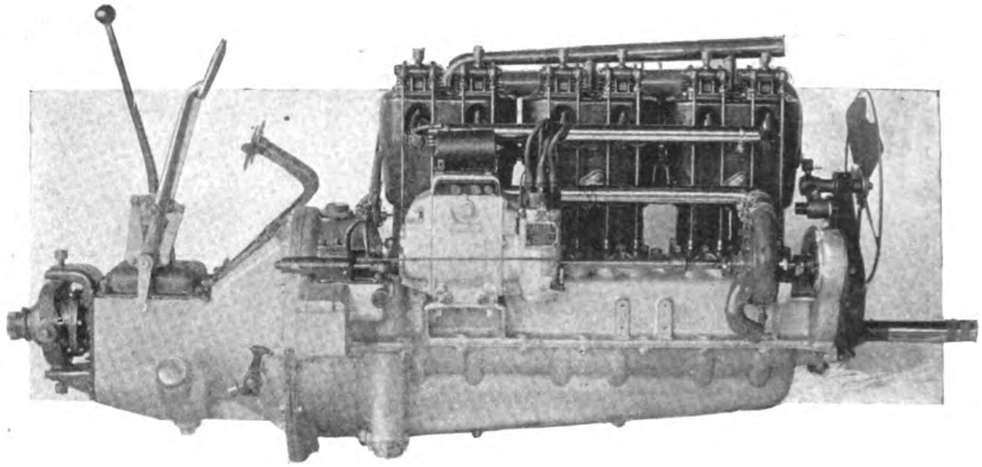
Camshaft Drive by Gears

A train of spur pinions communicates the movement from the crankshaft to the overhead camshaft. These intermediates have a ball bearing each side of them, one bearing being received in the cylinder casting and the other in the aluminum cover. The same applies to the camshaft pinion.

On the right side the water pump is driven off the train of pinions and on the opposite side the high-tension magneto is driven in a similar way. The revolution counter is driven directly off the end of the camshaft.

Lower Prices Feature New Buick Line

Tungsten Steel Replaces Nickel Steel in Valves—Multiple Piston Rings—Pistons 1 Inch Longer—New Upholstery and Equipment



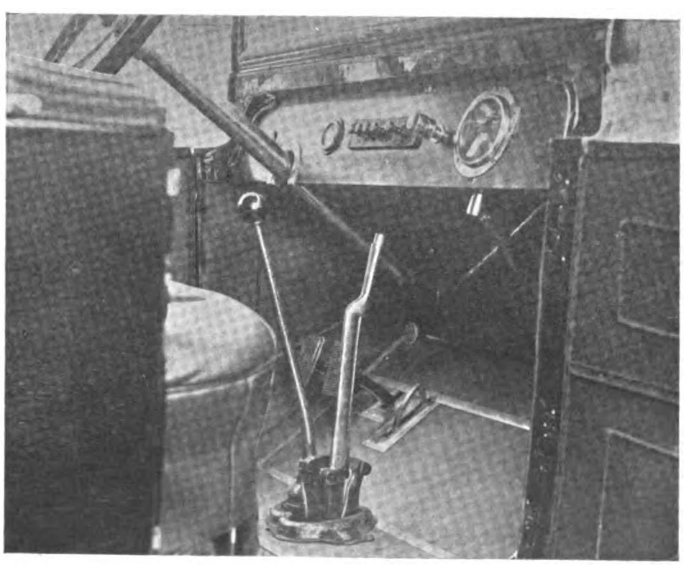
Right side of Buick six-cylinder unit power plant. The camshaft operating the overhead valves through rods is situated on this side as well as the Delco electrical system. Note mounting of gearshift and emergency brake levers and gearbox. Also specially designed universal joint at rear of gearbox for relieving the driveshaft of torsional strain

BUICK has reduced the prices on all of its models for 1915 and in addition has added many improvements. Tungsten steel valves replace the nickel steel ones; multiple piston rings succeed the individual types; improved piston lubrication is added; pistons are made nearly 1 inch longer; new upholstery is added; rain-vision windshields are fitted; inside top curtains have been fitted; and there are other minor improvements local to the different four and six-cylinder models.

Non-Skid Tires on Rear Wheels

The 1914 line of models is continued with the same trade nomenclature and the same general design. Motor sizes are the same, tire sizes have not been altered except that non-skids are now used regularly on the rears and plain treads in front; in a word, the 1915 models are refined continuations of the 1914 line.

The prices of the models have now been cut as follows:



Cowl board and control features in the new Buicks as found on the large four and six. Note mounting of speedometer in cowl board face

Model	Body	1914	1915	Reduction
C-55 (six)..........	Touring	$1,985	$1,650	$335
C-36 (four).........	Roadster	1,235	1,185	50
C-37 (four).........	Touring	1,335	1,235	100
C-25 (four)..........	Touring	1,050	950	100
C 24 (four).........	Roadster	950	900	50

The greatest price reduction has been made in the six, $335. Touring car prices are cut $100 and roadster prices, $50.

Bodies Are All New Designs

The bodies are all newly designed. Radiators have been rounded fully at the top; their edges have been coped over; hoods have been given more of a slope, and nowhere are there any protruding points to disturb the general impression of smoothness.

The upholstery on the larger cars is of modified European form. The formerly used leather padding extending over the edges of the body has been cut out and the upholstery is kept within the body lines of the car. Leather beading on the body edges without padding replaces the formerly used trim stick, and gives a distinctive touch.

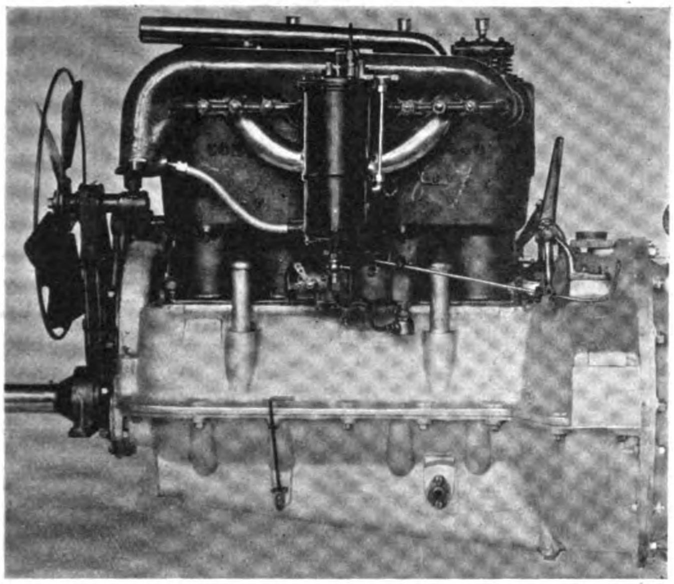
Cowl Board Added to Four

Concealed hinges are on doors of the fours, the six having them this season. Another four improvement is the addition of the cowl board which was used only on the six this year. This cowl board is very well arranged. One feature of equipment is the new type of sight feed used for determining if the oil is circulating. This little instrument has vanes rotated by the flowing oil. These also rotate a pivoted flat piece of metal rubbing on the inside of the glass face. Thus the glass is kept clean and the oil flow can always be seen.

New Ventilating Windshield

A rain-vision, ventilating windshield is new to all models, and adds to the appearance. Inside-operating curtains are another feature of the equipment, which is really complete in every detail. Special rigid tire carriers are fitted to the rear of the cars.

Although somewhat altered in body design, the changes in the mechanical features of the Buicks are very slight. Motors have come in for practically no alterations except minor



Manifold side of Buick four-cylinder unit power plant as used on models C-36 and C-37, showing vacuum gasoline feeder mounted above carbureter. This is a part of the Stewart gravity fuel feed system used on these cars

ones. The distinctive type of overhead-valve engine with gearset in unit is still rigidly adhered to, there being no differences in the cylinder dimensions. The type of drive inclosing the propeller shaft in a torsion tube also remains.

Pistons Lengthened 1 Inch

But what changes there are in the engine are well worth mentioning. In order to give a greater bearing surface to the pistons of the large four- and six-cylinder motors, and to eliminate any possibility of piston slap, the pistons have been lengthened 1 inch to 5 inches, and a new oiling feature has been incorporated in these pistons. On either side and directly above the piston pin bearing a gash has been made with a No. 3 B & S cutter. Drilled diagonally in the center of this gash a hole runs through the boss and opens into the bearing. Further, a relief groove is cut one-quarter around the circumference of the piston below the lowest ring slot. This scoops the oil on the cylinder wall and sends it to the gash where it passes through the drilled hole to the piston-pin bearing. Thus, little or no oil is wasted and smoking is nearly impossible, for any excess oil is trapped and must go within the piston.

New Type of Piston Ring

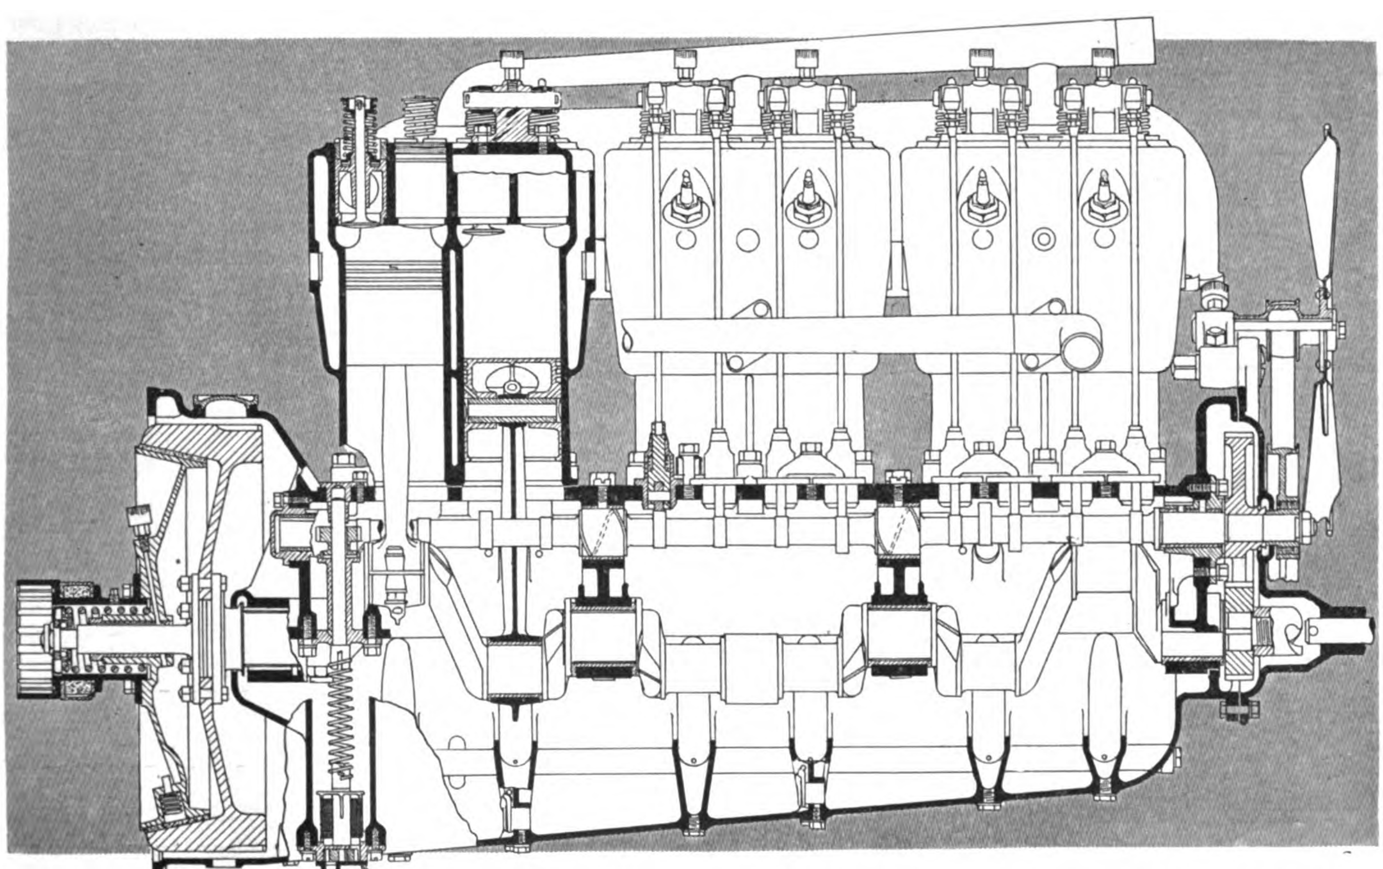
A new type of piston ring which is being adopted by many of the best known car manufacturers is used. Three thin steel rings are placed in each of the three ring slots per piston. These are a cold-rolled steel stock which is first coiled and then sawed, giving the separate rings. These are said to run in quicker, to hold the compression much better and they also take any wear.

Cylinders Cast in Pairs

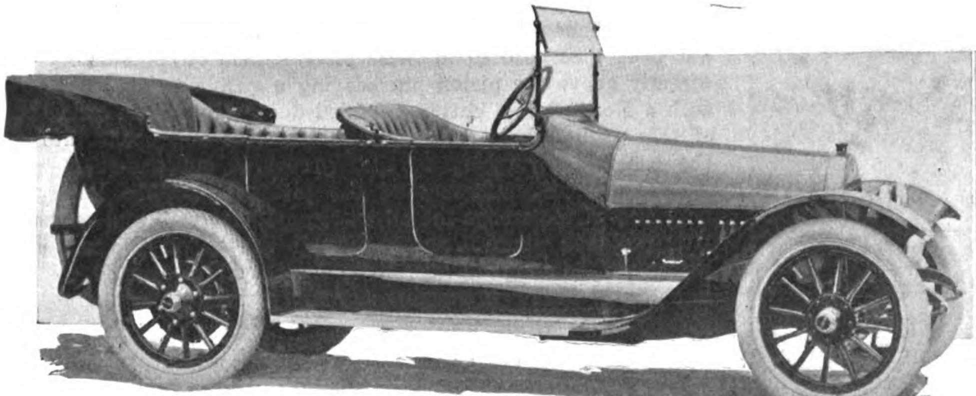
Reviewing the mechanical features of the two larger models, the six and the big four, there is really no difference except in the number of cylinders and the size of some of the parts, and in the rear springing which has already been commented upon.

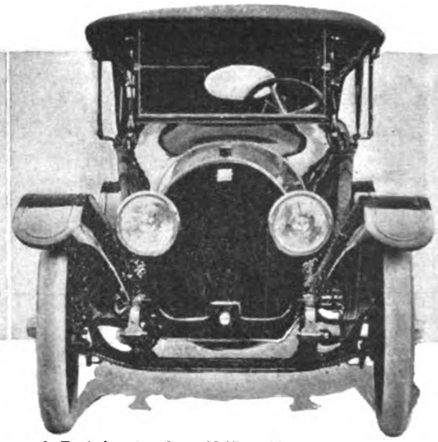
Cylinders of these motors are cast in pairs, their size being 3.75 inches bore and 5 inches stroke, giving the six a displacement of 331.35 cubic inches and the four, 220.9 cubic inches. Block tests have developed 42.5 horsepower for the four and 62-horsepower for the six, despite the fact that the formula ratings are 22.5 and 33.75, respectively. The stroke-bore ratio of 1.33 has much to do with this.

There has been no alteration of the valve mechanism. Ball-and-socket joints on the rods and rockers are used, which



Part sectional view of six-cylinder motor used on Buick C-55. This engine has developed 62 horsepower on the block. The cutaway section through the two end cylinders gives an excellent idea of the typical overhead valve construction used in Buick motors





Left—Side view of 1915 six-cylinder Buick model C-55, selling at $1,650. Right—Front view of Buick six for 1915. Note stream lines and attractive head-on appearance

make the working parts noiseless. The rockers are pivoted at their center to an arm common to each set of valves, which arm bolts to the top of the cylinder.

Exhaust Discharges Formed from Cylinders

The manifolding is peculiar in that the exhaust, with a separate opening into the header from each cylinder is carried above the intake which has a common opening for each cylinder block. The exhaust manifold also departs from the conventional in that the connection to the exhaust pipe is at the front end instead of the rear, that is, the gases pass forward to their outlet instead of back.

The combination Delco cranking, lighting and ignition system is with the Buick again, though much simplified over a year ago. It is of the 6-volt, single-wire type with grounded return circuits. The ignition part on the large fours and the six is now fitted with an automatic spark advance in addition to the regular hand advance on the steering wheel. Naturally this tends to more efficient motor performance, the automatic advance feature giving the needed spark variation above or below the set point as determined by the hand spark lever and within certain limits of this set point.

Simplified Delco Electrical System

The Delco apparatus has been greatly simplified by the elimination of the ignition relay and the cut-out relay, the operation now being through the switch on the dash which closes the ignition and generating circuits.

The unit incorporates a new system of current regulation which has for its main advantage the fact that battery charging is made easier, causing greater output at lower speeds than heretofore. To do this, the automatic spark advance and the ignition control are operated in combination by a centrifugal governor. This regulation shows a current output curve with a peak at speeds of from 1,000 to 1,200 revolutions a minute. This is at car speeds of about 10 to 12 miles an hour.

The model C-24 and C-25 Delco unit has its current controlled by a bucking coil, and the automatic spark advance feature is not used.

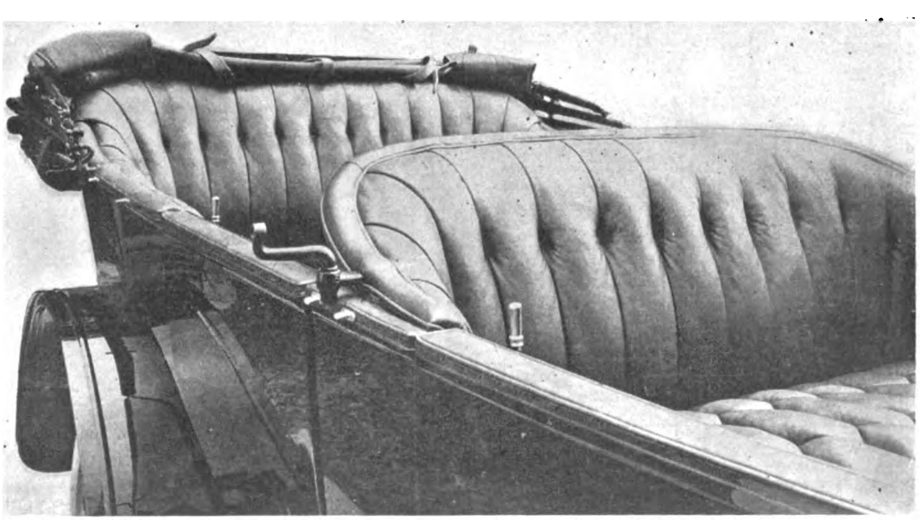
The cranking is done by connecting the electrical unit, which is temporarily operating as a motor, to the flywheel face gear by means of a pedal. Preliminary downward pushing sends a small current to turn the electric motor slowly and thus to readily mesh the gears, while complete downward pressure sends the full current for cranking.

Generator Runs at Engine Speed on Fours

The generator speed is the same as that of the engine with the four-cylinder types, while that of the six is run at one and one-half times engine speed. The gearing ratio for cranking, however, is the same for both the big four and the six, namely, 21 to 1. Eighteen to 1 is the reduction with the small four.

The storage battery used is an Exide located under the front floor boards. It is rated at 80 ampere-hours and is of the three-cell type. This unit is the same for all cars.

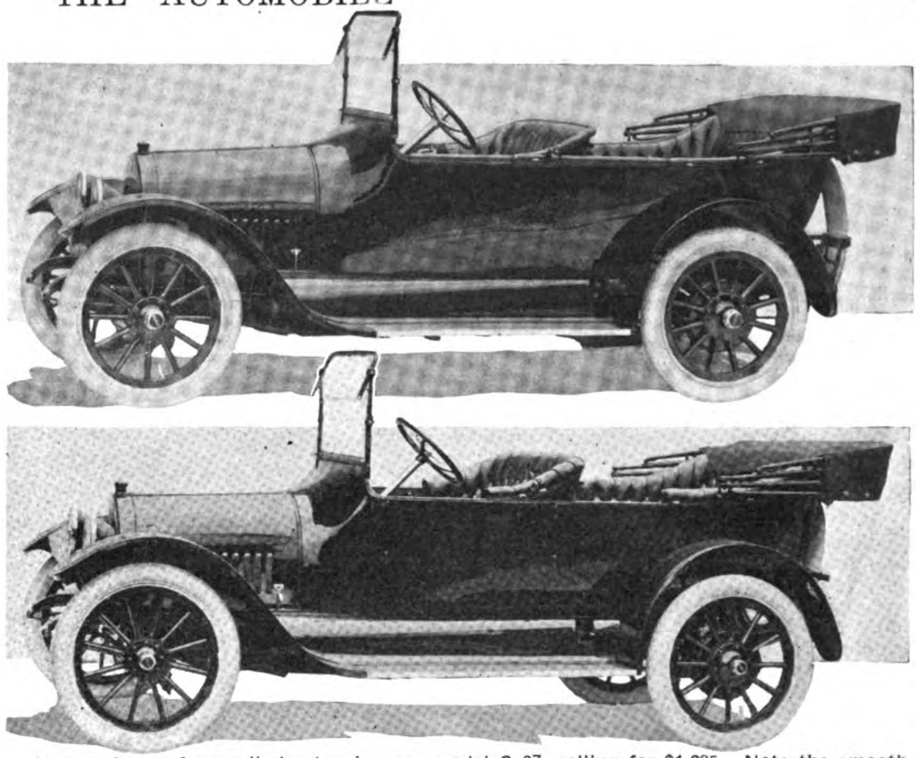
One special feature of note in connection with 1915 Buick wiring is that all wires are inclosed within conduits, even the connections between any two wires being within small T or L connectors. This should make the system proof against all conditions. Headlights are provided with dimmers, there being no side lights fitted.



Showing the new type of upholstery used on the larger Buicks. The leather cushions do not extend over the edges of the bodies and the leather trim of the edges replaces the trim stick

On the larger four-cylinder models and the six a new method of delivering the gasoline to the carbureter is employed. While the gasoline tanks are still carried at the rear and hung below the frame level, the force feed has been replaced by a modification of the Webb Jay, or Stewart, method of vacuum feed. The vacuum apparatus is mounted on bosses cast on the intake manifold, and is high enough so that the fuel can flow from it to the carbureter by gravity. The device is really a method of automatically creating a vacuum within it, thus utilizing atmospheric pressure to send the fuel to it. This gets away from all the troubles experienced with pressure feed due to leaks, pressure pump failure and the like.

As to the oiling system: A constant-level splash system with the lubricant circulated by a gear-driven pump operated by bevel gearing from the rear end of the camshaft is used. A distributing pipe located along the inside of the crankcase supplies oil to the several splash troughs under the connecting rods. The oil, which is splashed up into the cylinders and which finds its way through the gashed pockets in the sides of the pistons, flows down the inside of the crankcase where it is caught in ducts which convey it to all of the motor bearings.



Upper—Large four-cylinder touring car model C-37, selling for $1,235. Note the smooth-edged upholstery on the body; also rounded-over radiator and flush doors. Lower—Small four-cylinder touring car model C-25, selling for $950

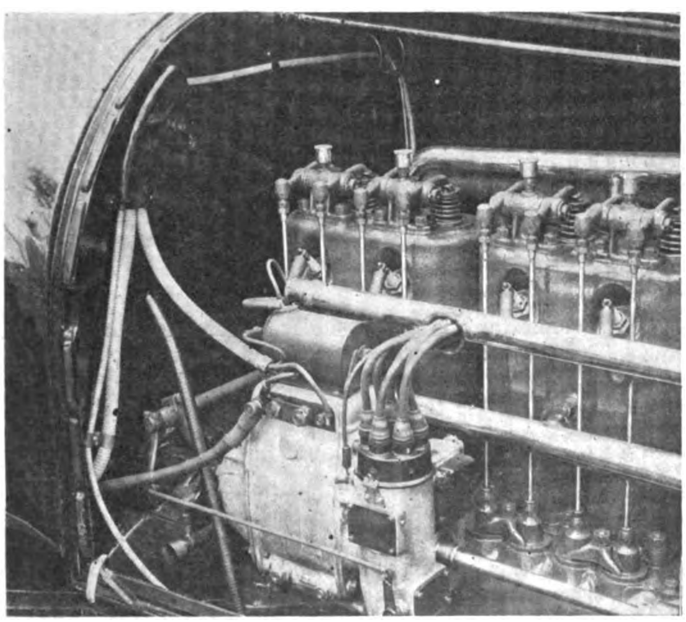
Three-Point Suspended Power Plant

The motor, gearset and clutch unit is three-point suspended conventionally from the main frame. The intake and exhaust manifolds are located on the left of the motor. The right is given over to the long push rods extending up from the camshaft to the rocker arms operating the valves and to the Delco electrical unit and water pump.

There is a change in the rear spring construction on the six-cylinder model only. Cantilever springs replace the three-quarter elliptics used this year. These are pivoted at both ends and have a length of 50 inches with a width of 3 inches. They have eight leaves with the shortest on top in the usual way. The lower leaf is rolled up at its ends to form a bearing for the spring bolts attaching it to axle and frame.

Little Four Has Separate Gearset

It should be mentioned here that the smaller four-cylinder chassis has a motor of the same overhead-valve type but its gearset is not in unit, nor is the piston stroke as long, although the bore is the same as the others. The stroke is 3.75 inches, giving a piston displacement of 165.6 cubic inches, and according the engine a horsepower of 30 on the block. While the motor has the new style of steel piston rings, its pistons are not gashed as are the others, nor is the vacuum system of fuel feed incorporated. The carbureter gets its gasoline by gravity from the tank under the seat on the touring car and back of the seat on the roadster. Pistons have come in for 1-2 inch of lengthening for the same reasons as set forth for the increased length on the larger motors.



Delco electrical unit as mounted on the larger Buicks for 1915, showing the inclosure of all wires in conduits. The unit is driven by a shaft from the timing gears and is mounted at the right rear of the motor, the starting motor operating on the flywheel

There is no difference in the drive or frame members of the chassis of any of the models over this year. The gearset is substantially the same for all with the exceptions of necessary size increases with the bigger cars. Center control is used, and with 7-8-inch face gears, shifting to one or the other of the three speeds is very efficient. Transmission gear ratios are 3.36 to 1 on first, 2.23 to 1 on second, and 4.32 to 1 on reverse. The clutch cone is of pressed steel instead of cast aluminum.

Instead of the regular strap fuses heretofore used, the switch on the cowl board is provided with a circuit breaker. This protects all the circuits except the generator circuit, in which the current flows both ways.

Special Universal Relieves Driveshaft Strain

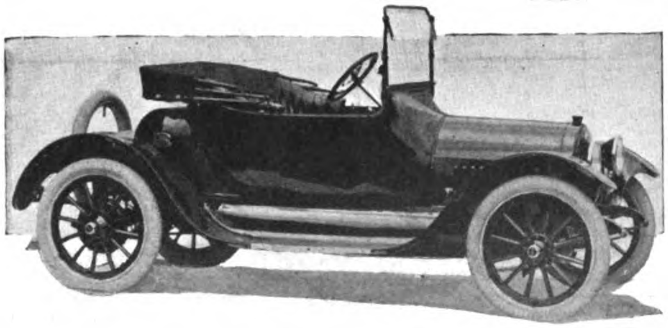
Drive is direct to the bevel gears in the rear axle, the usual construction of having a universal joint at the front end when the shaft is inclosed being used. The specially-designed Buick universal bearing on the front end of the third member relieves the universal joint of the driveshaft of any strain.

The fours have three-quarter floating axles with heat-treated nickel steel axle shafts carried on roller bearings. The six is fitted with a floating axle, its shafts being of nickel steel carried on annular ball bearings.

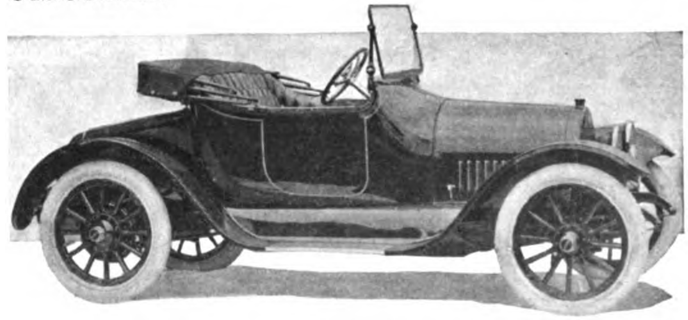
There is no change in wheelbase of any models with the exception of that of the small fours. The dimension has been made 106 inches instead of 105 inches. The other fours have 112 inches between wheel centers, and the six is still 130 inches.

Demountable Rims Are Standard

Tires have been retained at 32 by 3 1-2 for the small fours, 34 by 4 for models C-36 and C-37 and 36 by 4 1-2 for the six. Non-skids are fitted to the rear of all cars, the fronts being plain treads. Demountable rims are standard as formerly.



Small four-cylinder roadster Buick model C-24, selling at $900. Note the new rain-vision ventilating windshield



Larger four-cylinder roadster model C-36, selling at $1,185. Note the streamline body with rear deck

The Buick crankshaft for either four or six is a three-bearing one, the supports being of ample size. The camshaft has an equal number of bearings. Some motor dimensions follow:

	Six	Large Four	Small Four
Front crankshaft bearing..	1 7-8 x 2 7-16	1 7-8 x 2 7-16	1 5-16 x 3 5-16
Center crankshaft bearing.	1 7-8 x 2 1-2	1 7-8 x 2 1-2	1 5-16 x 2 3-8
Rear crankshaft bearing...	2 x 3 21-32	2 x 3 21-32	1 5-16 x 3 1-4
Front camshaft bearing...	1 3-16 x 29-64	1 3-16 x 2 29-64	1 x 2 11-16
Center camshaft bearing..	1 27-32 x 1 5-8	1 27-32 x 1 5-8	1 11-16 x 1 1-2
Rear camshaft bearing....	1 5-16 x 1 7-8	1 5-16 x 1 7-8	1 1-8 x 1 7-16
Crank pin bearings.......	1 7-8 x 2 1-4	1 7-8 x 2 1-4	1 3-8 x 2
Wrist pin bearings........	15-16 x 2 3-8	15-16 x 2 3-8	3-4 x 1 3-4
Valve diameter	1 1-2	1 1-2	1 1-4
Valve lift	9-32	9-32	1-4
Flywheel diameter	16.44	16.44	13.7
Flywheel weight	81 pounds	81 pounds	58 pounds

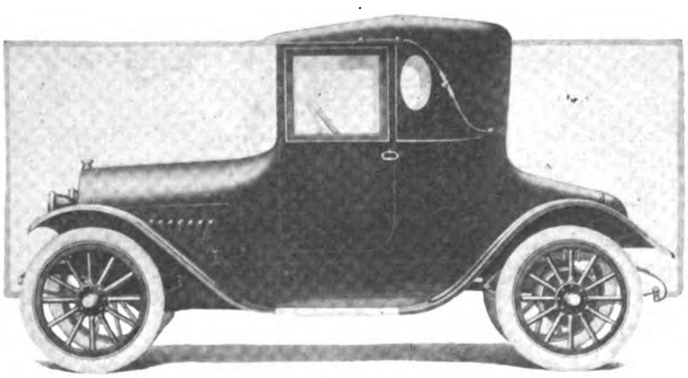
Bearing diameter is first dimension given.

Krit Company Adds a Cabriolet Body to Its Line

DETROIT, MICH., July 27—A three-passenger cabriolet body has been added to the Krit line and will be ready for delivery shortly after September 1. This body has been designed to meet the needs of physicians and others desiring a low-priced closed design. It will sell for $1,350 equipped with Disco starter and generator.

Streamline Type of Body

The radiator, hood and front end of the body are the same as those on the front of the roadster and touring designs which now make up the line. The entire exterior of the car is of curved design, giving a streamline form from the radiator to the end of the tapered rear deck. The driver's cushion is 16 inches wide and is placed slightly forward of the cushion for the other passengers. The larger seat for the two passengers is 32 inches in width. All the passengers face forward.



New cabriolet body seating three passengers, which has been added to the Krit line. This body is especially designed to meet the needs of physicians and others desiring a low-priced closed car. The price is $1,350 with Disco electric system. Deliveries will begin September 1

The upholstery used in the car is optional and may be of hand-buffed leather or cloth. The car is finished in blue with black running gear and gray wheels.

The Krit chassis which was described in THE AUTOMOBILE for November 13, 1913, has a four-cylinder L-head block, 3 11-16 by 4-inch motor. The motor, clutch and gearbox are a unit and are suspended from the chassis at three points. A notable feature of the motor is that the crankshaft is carried on two ball bearings. It is capable of 3,100 revolutions per minute. The rear axle is semi-floating. The car is driven from the left side and also has left control.

The Krit Co. state that although they got a late start for the 1914 season, only being able to supply a few demonstrators last November, business has been very good, foreign business having gone beyond the company's expectations while the domestic business is on the increase.

30 per Cent. Ahead of Last Year

The actual increase in volume for the past seven months is very close to 30 per cent. over that of the same period during the 1913 season. It is true that there has been, during the past few weeks, a slight falling off in some sections of the country but this does not seem to be universal, in fact business in some sections of the country with us is much better now than at any previous time during the season.

Aluminum Continued for Castings

Although many manufacturers of moderate-priced cars have discarded the use of aluminum for their crank and gearcases for some reason or other, the Krit company is still using this metal throughout the entire power plant wherever practical so that the power plant complete, including transmission, carbureter, magneto and fan, weighs but 368 pounds. The five-passenger touring car weighs less than 2,100 pounds, with standard equipment and only about 70 pounds, more when equipped with electric self-starter and generator.

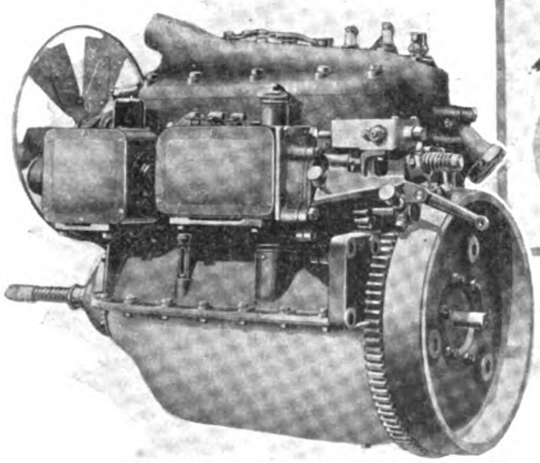
Bodies are exceptionally roomy and of the genuine streamline type, which lines have been fully completed by carrying them out into the rounded, tapering bonnet and rounded, tapering radiator.

Many Minor Refinements

The gasoline tank is placed under the shroud, making for convenience, a more positive feed to the carbureter, and also has allowed for a reserve supply. The upholstering is deep and the seats low so that the occupants sit in the body and not on top. An instrument board, leather covered, conceals the gasoline tank. On this instrument board is mounted the electric light switches, the steering post bracket, flush type speedometer, flush type ignition switch and the gasoline tank filler. The steering wheel is large, having nickel plated spider and nickel plated spark and throttle levers on top. The floorboards and running boards are covered with cork linoleum with aluminum binding. The top is of mohair, equipped with Jiffy curtains and mohair top cover. The windshield is built into the body without the use of stay rods and is of the clear vision, double ventilating type.

1915 Maxwell 25 Price Cut $55

Complete Gray & Davis Electric System $55 Extra



Left—Left side of four-cylinder block motor used in Maxwell 25 for 1915. Note mounting of Gray & Davis cranking motor and generator on brackets on the upper half of the crankcase

Above—Side view of Maxwell 25 five-passenger touring car for 1915 with top up, showing new sloping hood rounding into the cowl in which the gasoline tank is located. The front edge of the radiator is rounded over. The fenders are crowned. This car sells for $695 as compared with $750 for the 1915 model

THE price of the Maxwell 25 for 1915 has been reduced $55 on all models, this reduction notwithstanding the fact that many body improvements have been made and several chassis alterations effected. It includes gas headlights and oil side lamps. If you want the complete Gray & Davis electric cranking and lighting equipment you pay $55 more, or in other words, you get the complete electrical equipment for the same price that the car sold for this year.

The touring car lists at $695. The roadster lists at $670, the town car at $920, and the cabriolet, which is a new body type, at $840. These figures include gas and oil lighting. Add $55 to each for the electrical equipment.

Maxwell Features

Streamline Cowl and Hood
Fuel Tank on the Dash
Two-Piece Windshield
Dash Instrument Board
Crowned Type of Fenders

The Maxwell 25-body style is new in many respects. There is now a sloping hood which rounds into the cowl where the gasoline tank is carried instead of under the front seat as formerly. The front edge of the radiator is rounded over. There is a new two-piece windshield. Crowned fenders are used, and the space between these fenders and the body in front and rear completely inclosed. An instrument board is added, and back of it is located the gasoline tank with filler pipe at the right of the board. The wheelbase remains at 103 inches on all models.

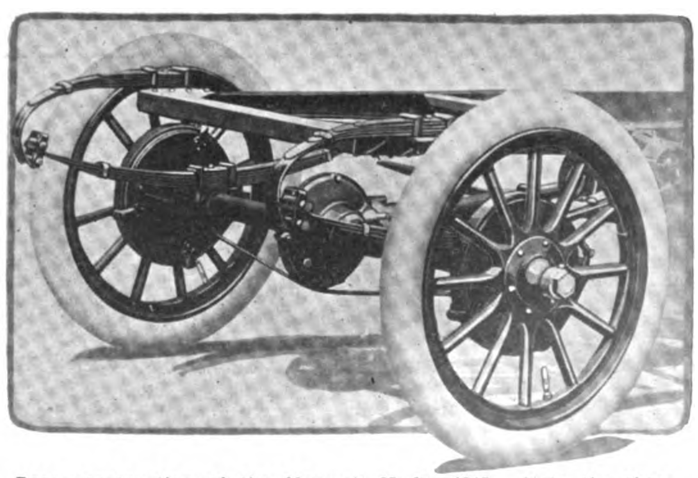
The Starting Equipment

When the Gray and Davis cranking motor and generator are supplied they are carried on brackets on the left side of the upper half of the crankcase. The brackets are cast integrally with the case. The generator is placed ahead of the motor, to be in line with the fan pulley, from which it is driven by belt. Thus the same belt drives the fan and the generator in triangular fashion. The pulley diameters give the generator a speed of 2¼ times that of the crankshaft, and it charges the battery at the full rate when the car is running from 12 to 15 miles an hour.

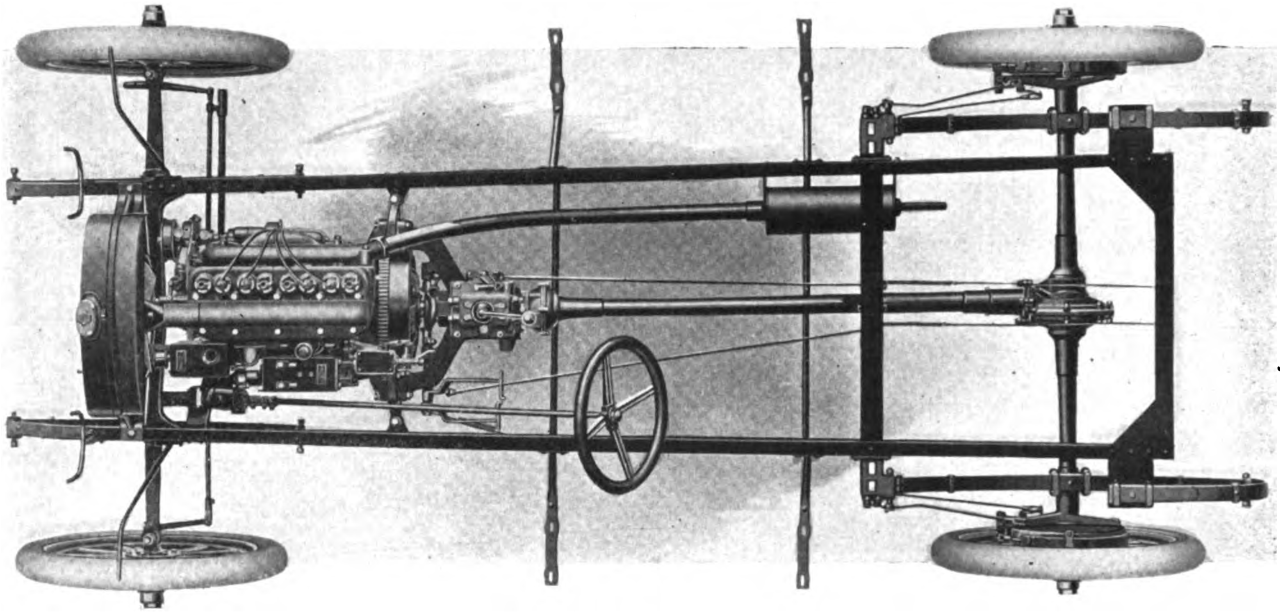
The cranking motor, which has the ability to spin the engine at the rate of 130 r.p.m., is fitted to gear to the teeth of a ring gear fixed to the outer rim of the flywheel. The gear train between the electric motor and the flywheel gives a relative electric motor to engine speed of 30 to 1. The shifting for cranking is of the usual form. Pressure by foot on the plunger pedal starts the electric motor and engages the starter pinion with the flywheel.

In connection with the electric system a Pumpelly storage battery of 80-ampere hours capacity is used. In accordance with general practice these days, there are no side lights with the electrically equipped Maxwell. The 9-inch headlamps are fitted with a dimming coil in the switch which serves to reduce the light for city driving.

Mechanically, the chassis is practically as in 1914, although

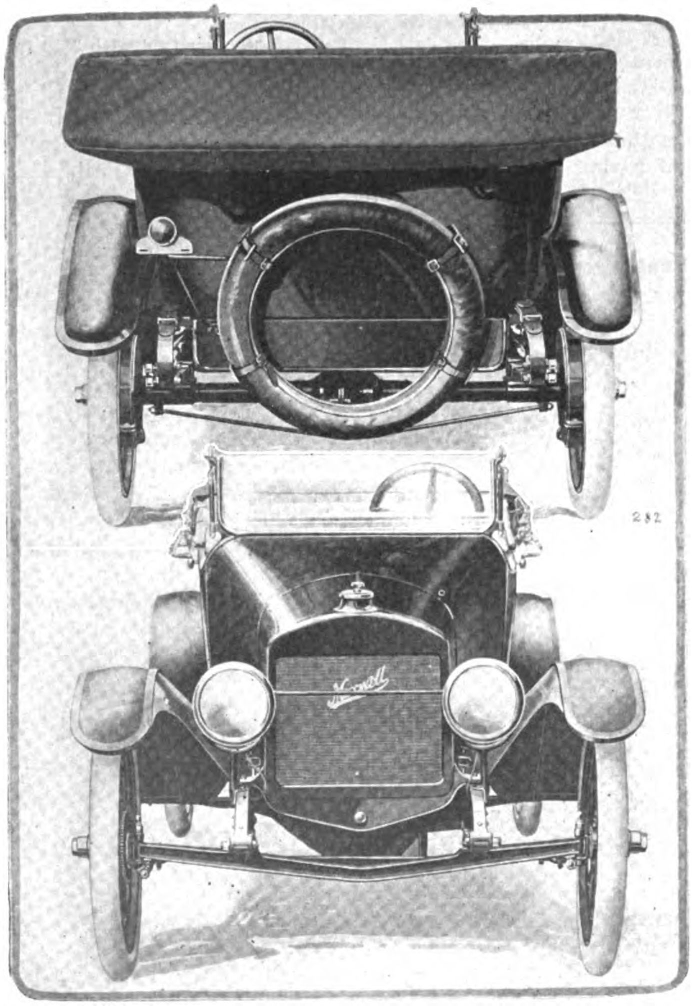


Rear construction of the Maxwell 25 for 1915. Note the three-quarter elliptic rear springs



Plan view of Maxwell 25 chassis for 1915, showing extreme simplicity of construction. Note unit power plant suspended at three points and mounting of compact gearbox for center control

several refinements are included. First is the replacing of the semi-elliptic rear springs which connected to spring horns at their rear ends with three-quarter elliptic rear springs with scroll ends.



Above—Rear view of Maxwell 25, showing tail light and license bracket combination, new crowned fenders and mounting of extra tire

Lower—Front view of Maxwell 25, giving an idea of the new streamline hood and cowl as well as of the rounded front on the radiator

A second change is the shifting of the carbureter from the left of the engine to the right. In the older motor, although the valves were on the right, the fuel went through a passage cored in the cylinder casting. This change was made to make room on the left for the cranking and lighting units, when they are specified, but it has the advantage of making a shorter passage for the gases. In its new location the Kingston atomizer type carbureter is in rear of the magneto and very accessible, being higher up than formerly on account of the higher position of the fuel tank in the cowl as compared with its former position under the seat.

A third new feature is the radiator construction. The radiator shell which is rigidly fastened to the frame is entirely independent of the core which carries the cooling water tubes. Thus the delicate part though securely held in place does not receive all the frame weaving strains which the shell does and the possibilities of springing leaks and damaging the tubes are reduced to the minimum. Replacement of the core is also made cheaper and easier by this construction.

New Control Features

Although drive is still on the left and the control in the center, a new type of steering post which fastens by a bracket to the cowl board for rigidity is used. Instead of the former spark and throttle lever arrangement wherein the two levers were on opposite sides of the steering column, they are both now mounted on a quadrant. It is below the wheel. An added refinement is the placing of the horn button on one end of the quadrant and convenient to the driver's hand.

Motor Is Little Altered

Reviewing the Maxwell chassis constructional features, the motor first commands attention. It is practically as it was in design except for the carbureter shifting and the provision for the mounting of the electrical units. The cylinders are cast in a block with the cylinder head detachable and suspension at three points in unit power plant form. Although the flywheel is unenclosed, the gearbox is made a part of the unit by a yoke circling the flywheel and bolting at either side to the integral crankcase supporting arms.

The cylinders 3 5-8 by 4 1-2 have a piston displacement of 185.8 cubic inches, a stroke-bore ratio of 1.24 and a S. A. E. horsepower rating of 21.1. The maker rates it at 25 horsepower under normal conditions, and it is probable with its long stroke that it will turn up an excess of this amount on the block.

The crankshaft has two main bearings, and it as well as the camshaft and connecting-rods are constructed of manganese steel which is very rigid. Timing gears, housed at the front, are made of nickel steel and all working parts are well designed to be as light as possible and consistent with the work they have to do. Their dimensions should make for efficient operation.

Several motor dimensions follow:

Crankshaft bearing diameter—1⅞ inch.
Front main crankshaft bearing length—2½ inches.
Rear main crankshaft bearing length—3 inches.
Connecting-rod lower bearing length—1½ inch.
Valve diameter—1 9/16 inch.
Camshaft bearing diameter—1 inch.
Front camshaft bearing length—2 inches.
Rear camshaft bearing length—1¾ inch.
Wrist pin bearing—¾ inch diameter; 2¾ inches length.

Troughs for Connecting-Rods

The lower half of the crankcase carries the oil reservoir used for splash lubrication. A plunger pump located in the timing gear case, and operated by an eccentric on the camshaft, lifts the oil from the reservoir to the four splash troughs under the connecting-rods. After the oil has been splashed onto the various bearing surfaces by the rod ends, it finally finds its way back to the reservoir through a drain at the rear of the case and after being filtered is recirculated.

Thermo syphon cooling is used. A Simms dual type high-tension magneto driven by shaft on the right gives the ignition current. It may be locked from the dash.

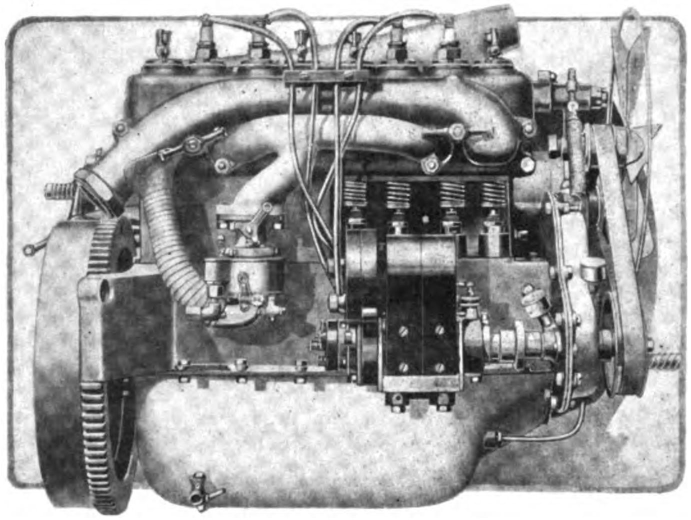
The clutch is a cone type with asbestos lining, the cone being a steel stamping.

The gearset is unaltered and affords the usual three forward speeds. Gears are nickel steel, and Hyatt bearing in connection with a bronze bushing is used at the front end of the main shaft. The rear end is carried on a babbitt-lined bearing. Phosphor bronze bushings are used on the jack-shaft.

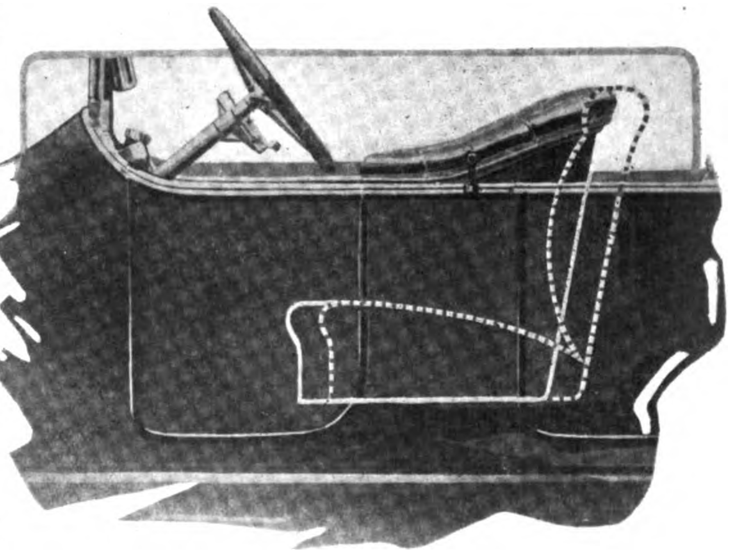
The propeller shaft is inclosed within a torsion tube with one universal joint at the front end. There are no radius rods, the tube taking the drive and torque. Other members are unnecessary with a chassis of this weight.

Three-Quarter Floating Axle

The rear axle is a three-quarter floating type with conventionally constructed bevel gearing and with the springs mounted above it. Brakes are of the usual contracting and expanding type acting on rear wheel drums. The standard wheel equipment calls for wood wheels with 12 spokes front and rear, on which clincher rims are fitted. These carry 30 by 3 1-2-inch tires all around.



Right side of Maxwell 25 motor, showing mounting of magneto and carbureter together with flexible hot air intake for carbureter. Note drain cock at bottom of crankcase



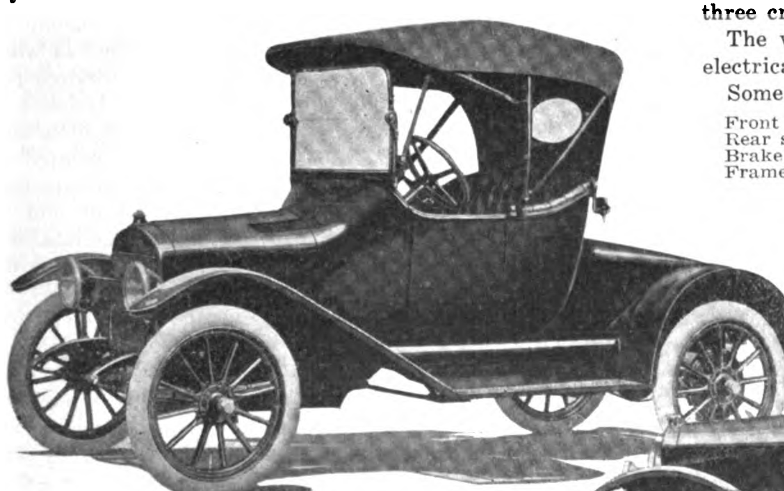
Adjustable front seat on new Maxwell 25. The dotted lines show the two positions which may be obtained by shifting the seats

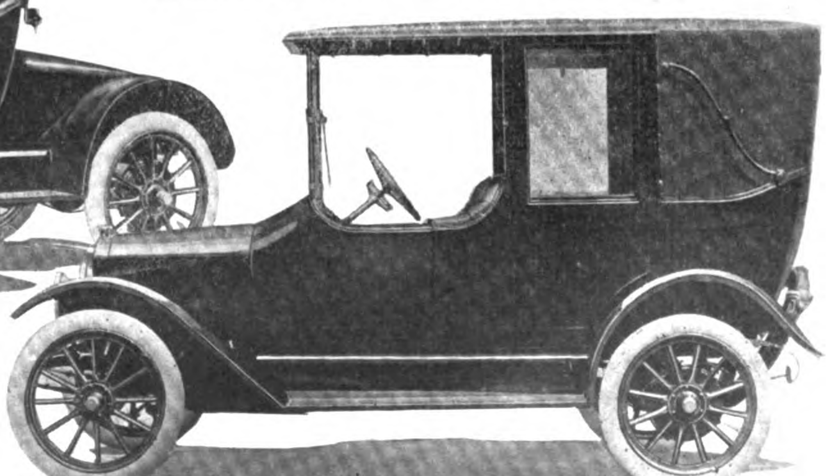
To insure good body support, the frame is tapered from 33 7-16 inches at the rear to 28 inches at the front. There are three cross-members.

The weight of the touring car is 1,850 pounds, this with electrical equipment and ready for the road.

Some chassis dimensions are:

Front springs: 1¾ inch wide; 32 inches long.
Rear springs: 1¾ inch wide; 40 inches long.
Brake drums: 12½ inches diameter.
Frame: 3½ by 1½ inches channel section; 5/32 inch metal.



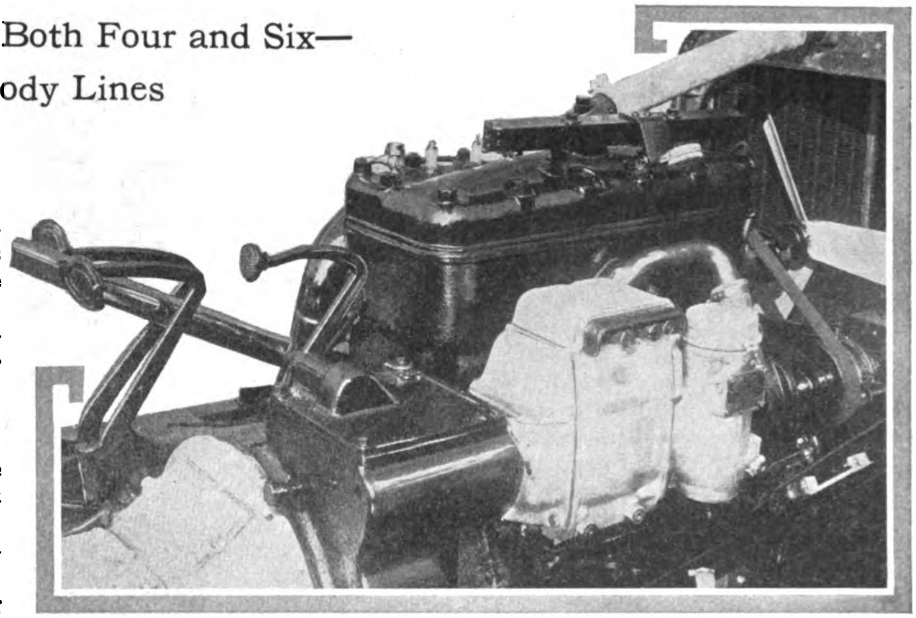


Above—New Maxwell 25 roadster with windshield and top which sells for $670. Note flush sided doors and streamline form of hood and rear deck

Right—Maxwell 25 town car which lists at $925. Note clean running boards, crowned fenders, mounting of extra tire at rear and landaulet type top

Two Oakland Chassis for 1915

Five Body Types Fitted to Both Four and Six—Improved Boat Body Lines



Right side of 1915 Oakland four-cylinder motor, showing mounting of the Delco electrical unit on the right

THE Oakland program for 1915 has been narrowed down to two chassis—a four and a six. On these, five types of bodies are fitted.

The four-cylinder model 37, is a much-altered continuation of model 35, the smaller four of 1914. Its price is still $1,200 and it is difficult to imagine a more refined and attractive light car.

The six-cylinder model, Six-49, is the new edition of this season's model 48. It is reduced in price $100 to $1,685.

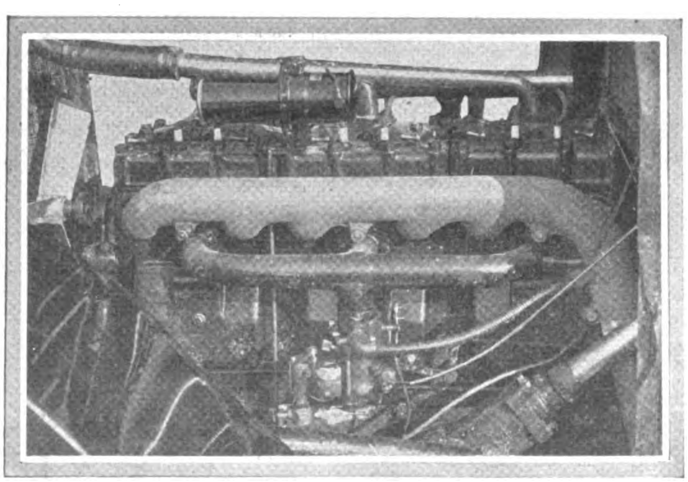
The 1914 model 43, has been discontinued.

Both new models reflect the designing hand of the company's new engineer, Eric Wahlberg. The four is not only mechanically practically a new job throughout, but its body lines are truly European. The six has not come in for much mechanical change, but its body lines have been much modified and hold to practically the same design as the four, on a somewhat larger scale.

Boat Body Lines Improved

The body lines are a modification and improvement of the boat body lines which have appeared in Europe. Beginning at the cowl, the upper edge sweeps in a very flat curve to the rear, while the contour of the cowl itself is scarcely a break from the slope of the hood. The latter is full rounded at the top, and the radiators have been shaped to preserve the general line. They are V-shaped in still better design than heretofore.

Though very similar in outward appearance, the two models are widely different in mechanical construction, and because of this fact, they will be described separately. The four-cylinder model, with its many new features naturally comes first.



Valve side of compactly arranged six-cylinder motor used in model 6-49 Oakland

With its motor refined, and its maximum speed increased; with completely re-designed frame; with a new type of drive and with the elimination of a great many brake rod and lever bearings due to the use of special spring pivot mechanisms, the four-cylinder model 37 has little in common with its predecessor, and with even greater strength and stamina, is several hundred pounds lighter.

The motor comes nearest to corresponding with that of last season's car. It is still 3.5 by 5 inches. It is suspended, as have been all previous Oakland motors, at three points.

A High-Speed Type Motor

Engineer Wahlberg characterizes the motor in its new form as a high-speed type, it operating up to 2,500 or 2,600 revolutions per minute. This is brought about by decreasing the weight of the reciprocating parts; by increasing the valve diameter and lift; and by proper manifolding in which the gas passages are not restricted and the cylinders permitted to draw in a full charge when the throttle is open.

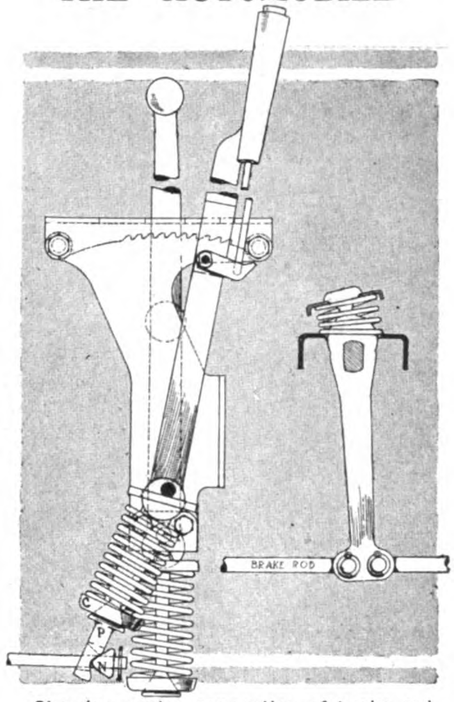
This latter is achieved by arranging the throttle axis parallel with the center line of the motor. It is pointed out that every throttle mounted in the regulation way at right angles to the motor center line acts as a deflector and the flow is not symmetrical with respect to this center line. The throttle arrangement as Oakland now uses it is said to distribute the gases equally either way.

Pistons Have Been Crowned

No alteration has been made in the three-bearing crankshaft, but the pistons have been crowned so as to make them as strong as possible with the lightest weight. In line with the growing tendency, they are fitted with nine thin carbon steel rings, three to each ring slot. These rings have square joints, and will very soon lap themselves into the cylinders due to the small wearing surface. Due to the multi-ring construction, the gas has to leak through nine places instead of three or four as is the case with the old type of rings before any compression is lost.

The L-head cylinders are cast in a block with the head detachable as this year. It is securely held in place by a number of holding bolts arranged in bosses around the edge. This head when removed completely exposes the piston heads and the inside of the cylinders.

Intake and exhaust manifolds are on the left, the former above the latter allowing the carbureter to be conveniently located. Valve springs and stems are completely inclosed on this side, the covers having breather vents in them. The valves are of tungsten alloy steel and have been increased from 1 9-16 inch in the clear to 1 5-8 inch. Timing gears are spirally cut.



Showing wedge connection of brake rod end to lever, eliminating bearings, on model 37 Oakland

Radiator Capacity Increased 20%

The motor is positively cooled by a centrifugal pump located ahead of the Delco electric unit on the right side. It introduces the water into the center of the jacket on the right. The radiator has 20 per cent. larger capacity and is of the fin-and-tube type, made narrow in order to easier take the strains which are put on it when the frame twists on uneven roads. The large tank top has been continued, thus carrying considerably more water than can be contained by a flat type.

Stewart Vacuum Fuel Feed

Although the gasoline tank is still placed at the rear and below the frame level, it does not feed by pressure as formerly but, instead, the Webb Jay, or Stewart, vacuum-gravity system of introducing the fuel into the carbureter is employed. The vacuum tank is mounted on the front of the dash and it is connected to the intake manifold. This latter creates suction enough to draw the gasoline from the rear tank to the vacuum tank on the dash. This has upper and lower portions, the upper filling first, the float in it raising as the amount of gasoline increases. When the level has reached a certain height, this float trips a valve mechanism which shuts the vacuum line off and opens the upper portion to the atmosphere. This will send the gasoline into the lower part of the tank which part is open to the atmosphere always. It connects with the carbureter and in this way gravity feed is obtained with the tank in the rear.

The motor has the latest type of Delco combination electric unit, mounted on the right side and driven from the front gears when operating as a generator and gears to the flywheel through a gear train when performing the cranking function, and has the ignition distributer in unit with it.

Single-Wire Electrical System

The system is of the 6-volt, single-wire type with grounded return circuit, is simple and reduces the wiring to the minimum. The principal improvement in the Delco unit this year is the current control which is connected with the automatic spark advance, another new feature. The latter consists of a centrifugal governor which automatically advances the spark when the speed of the motor increases within a certain range of the position set by the hand spark advance lever on the steering wheel. The current controlling device is purely mechanical, and consists of an arm wiping a brush over a coil wound so as to cause maximum current output at low car speeds. Thus the main advantage is that when the car is being driven at ordinary low speeds of from 10 to 15 miles an hour the battery is being kept charged.

This will be appreciated by those who do much city driving, and whose lights burn considerably, while they also use the starter a great deal. Such drains would soon discharge the battery were it not being charged at nearly any driving speed.

The gear reduction between the Delco unit and the flywheel for starting is the same as this year, namely, about 25 to 1.

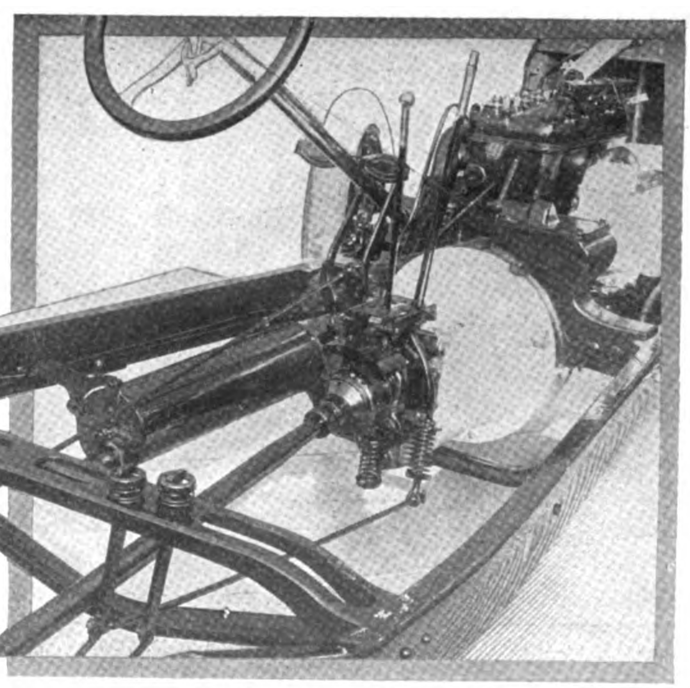
The gear train, which is shifted into mesh with the flywheel face gear by pushing a pedal, is completely housed within a case which is integral with the flywheel housing and the right rear supporting arm. As a generator, the unit is driven at engine speed.

An Exide battery of 80 ampere-hours capacity and carried under the front seat is a part of the electrical equipment.

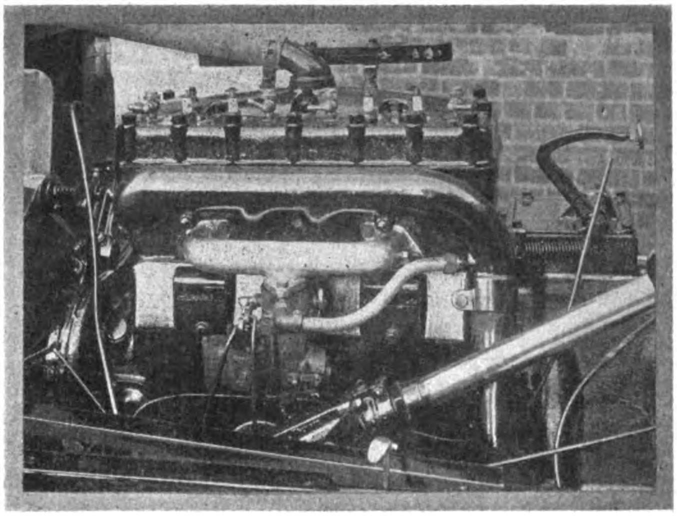
In connection with the lighting system, the headlights are provided with a dimming attachment, thus eliminating side lamps. The ignition distributer which was separate from the main electrical unit is again made integral with it. Another refinement is the locking of the electric horn button by the ignition switch, that is, when the ignition is off, the horn circuit is also disconnected.

The cone clutch has six spring inserts. An oiling device for the clutch shifting collar has been added. The grease cup mounted on the end of the clutch shifter shaft leads through a hole on the inside of this shaft, through the tube into the box on the clutch shoe, thus lubricating it.

Bolted to the flywheel housing is the three-speed gearbox, which is unchanged in design. The center control is principally the same as it was, although all bearings of both



Brake rod scheme on model 36 four-cylinder Oakland, which eliminates all bearings, springs on rocker shafts and wedges replacing them. These are noiseless and free from rattle due to the springs. They require no lubrication



Valve side of four-cylinder block motor used on model 37 Oakland

emergency brake lever and shifting lever have been eliminated. The sketch on page 217 shows the method of doing this. Springs on the bottoms of these levers hold their small trunnions down against fixed supports and thus allow them to oscillate or rock back and forth within the necessary limits. These springs take up all wear and the constructions eliminate any necessity of lubrication at these points.

Unnecessary Bearings Eliminated

By a similar use of springs and wedges, many bearings of like nature are eliminated, thus reducing the necessary care the owner has to give his car to the minimum. Throughout the brake operating system, there are no bearings to take care of, or places to oil. On the brake rods, on the clutch shifter, on the clutch link, on the emergency brake, on the control lever and on the brake rocker shafts which are under the center cross-member this is true. The brake rocker shaft levers get their oscillatory freedom through the compressibility of the springs which hold them in place by retaining cups. These cups may readily be removed by turning them at right angles to their fastening position so that their larger slots will clear the heads of the rocker levers. This same principle of removal applies to the other spring mountings referred to.

Special wedge connections of the brake rods to their lever ends are also original. These are shown in the sketch on page 217. The threaded end of the rod passes through the end of the lever which has its front side concaved to take the edge of a wedge which screws onto the threaded rod end A cotter pin beyond it and through the rod prevents its coming off, while it is self-locking due to its fitting into the concaved lever end. Adjustment is therefore very easy. The great advantage of these connections is that they may be allowed to rust or get mud-and-water-soaked without interfering with their operation.

Lower Spring Leaves Take Drive

The drive to the rear axle is of the Hotchkiss type, replacing the formerly used design with inclosed propeller shaft. In the new construction, the lower leaves of the rear springs are so constructed as to take the drive and the torque, in that sudden shocks are not transmitted to the chassis mechanism, the springs giving a cushioning effect. This construction is also lighter.

Instead of the solid propeller shaft heretofore used, the model 37 is equipped with a tubular shaft of 1 1-2-inch outer diameter and 1-8-inch wall. It is of medium carbon, seamless tubing, the stub ends of the universal joints being electrically welded on either end. Though 50 per cent. lighter than a solid shaft, it is much stiffer. It will not whip as would a heavier shaft.

The rear axle is a one-bearing, floating type and replaces the three-quarter floating design of last year. Axle shafts and gears are nickel steel, and Hyatt bearings are used in wheels and differential with New Departures in the third member.

The frame is of entirely new form, and made to be directly under the side panels of the body, all along, giving it proper support, and eliminating the necessity of using side aprons on the car.

The frame channel is 4 1-4 inches high of 5-32 inch stock. It is 139 inches long over all, has a 4 5-8 inch kick-up at the rear and tapers to the front. The rails are 40 3-4 inches apart and parallel at the rear for 36 inches. Here is located a cross member, and ahead of it the narrowing commences, following the body line forward until at the front the rails are 30 inches apart.

Front Springs Overslung—Rear Underslung

The springs are mounted directly under the frame rails, and not on overhanging brackets, which are heavy and put considerable strain on the cross-members. The scroll at the rear is directly through the gusset plate. The front springs have been placed over the axle again, they being underslung from it last year. Rear springs, however, are underslung

as formerly. Fronts are 35 1-4 inches long and rears 48 inches.

The wheelbase is unchanged at 112 inches, and tires are 33 by 4 inches on demountable rims. The equipment includes a one-man top, rain-vision, ventilating windshield, and all other features of the modern car.

Concealed door hinges and a wider rear seat are provided, while the upholstering is new in that the tufted edges do not protrude over the sides of the car as they formerly did. This is in line with a growing tendency in the newer cars. A roadster body is offered as well as the touring car.

Six-Cylinder Model Six-49 Chassis

The six-cylinder Oakland is fitted with either the touring car body, which will carry seven, due to the addition of auxiliary disappearing tonneau seats, or with roadster or speedster body. Its wheelbase is still 123 1-2 inches.

The motor has come in for the same improvements as those enumerated for the four. The bore and stroke are the same, the cylinders are cast in a block with detachable heads, and the crankshaft has four main bearings. The general engine design throughout is the same as that of the four.

Chassis Is Unchanged

Equipped with a three-speed gearset, cone clutch, unin-closed drive shaft and floating rear axle, the car is really a continuation of last year so far as the chassis is concerned. Springs are underslung both front and rear and measure 41 1-4 and 50 7-8 inches in length, respectively.

Tires are 35 by 4 1-2 inches in size on demountable rims, and equipment is complete. Like the smaller car, the vacuum fuel feed is used, and the Delco electrical unit with its new features is also fitted.

Big Field for Cars in South Africa

DETROIT, MICH., July 26—C. H. Dunlap, export manager of the Hupp Motor Car Co., who has returned to Detroit after an absence of 22 weeks spent in investigating sales conditions of the motor industry in South Africa, states that there is a very good future for the automobile industry in South Africa, and that there is not a foreign country where motor cars can be used to greater advantage. The reason is due to the very poor railroads that there are throughout the Union. The lack of transportation facilities makes it necessary for the South African to use some other means of locomotion than the ox-cart, and right here is where the automobile steps in.

Commercial travelers use motor cars in great quantities. They help develop their territory and enable them to call on small towns surrounding the large cities. Mine operators use motor cars extensively, and even the Boer farmers, who live in the interior and who formerly went to town two or three times a year, now are able to make regular trips to the big cities, and it is uncommon when a week goes by and a farmer does not go to town.

The roads around the large cities of Cape Town, Johannesburg, Port Elizabeth and Pretoria are in very excellent condition. Roads outlying the cities to any great extent are very poor and in many sections there are no roads at all—one has to run right across the "veldts."

There is a project on foot which has been sanctioned by the Colonial government, to establish good roads and improve roads now through the country, for which five million dollars has been appropriated. This work of road improvement has already been started

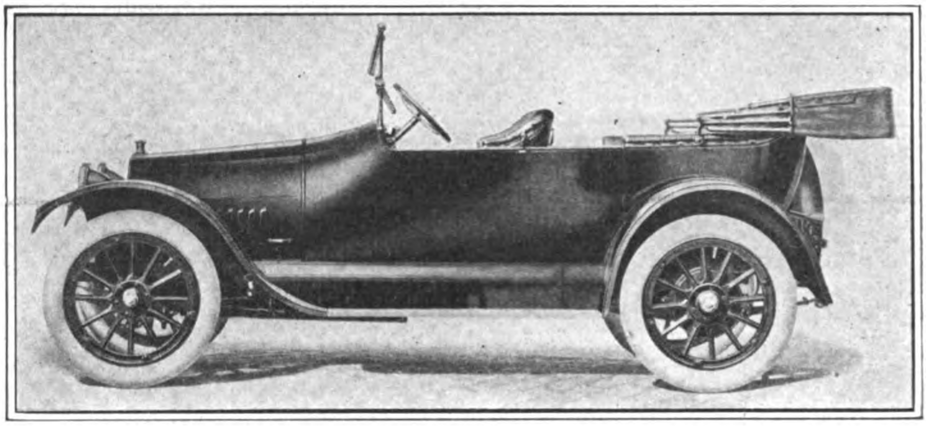
New Mitchell Light Four at $1,250

4 by 5 1-2 Inch Motor of L-Head Type with Cylinders Cast in Pairs—Unusual Equipment



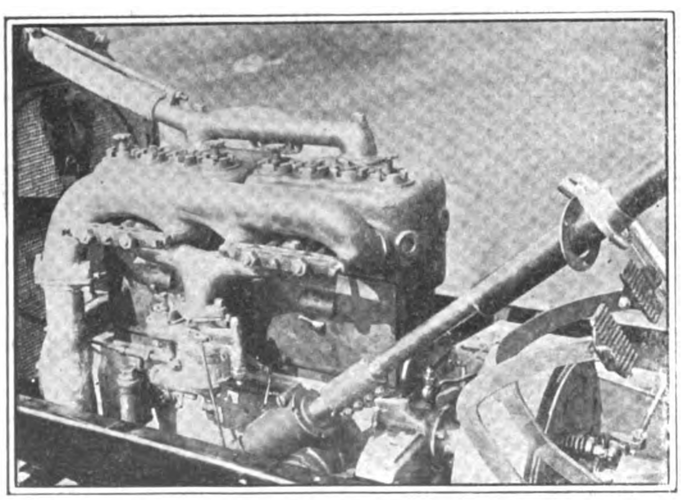
Side view of Mitchell Little Four for 1915 selling at $1,250

A FOUR-CYLINDER, 35-horsepower car at $1,250 with liberal equipment and with constructional features making for easy and inexpensive maintenance is the feature of the Mitchell line for 1915. The more powerful and more expensive chassis models, the Special Four, the Special Six and De Luxe Six upon which two, five, six and seven-passenger bodies and closed bodies are fitted, are continued practically unchanged for 1915.

The Mitchell line is now complete with a line of models ranging from 30 to 60 horsepower and well fitted to cover the greatly broadened selling field in which the company is now prepared to compete. The older models are too well known to require description here. Interest centers in the new Little Four.

Unusually Large Water Jackets

The Little Four has a four-cylinder engine of 4 inches bore and 5 1-2 inches stroke. The cylinders are cast in pairs and are of the L-head type with unusually large waterjackets. The engine has pump cooling, and ignition is obtained from the storage battery and generator of the Mitchell cranking and lighting system. The engine drives through a very accessible cone clutch of new design to a gearset amidships which gives three speeds forward. From here the drive is taken through a shaft in a torque tube and a single universal joint in the floating axle.



Left side of motor of Little Four, showing manifold attachment and collar holding two-piece steering column. Note that exhaust manifold leads to the front of the motor, down and then back

The drive is on the left and the control is center. The wheelbase is 116 inches and tires are 34 by 4 inches. Two-, five- and six-passenger bodies are fitted as stock at present, although coupé, sedan and limousine bodies may be obtained later.

Features of the equipment, in addition to that usually found on a car of this price classification, include a one-man top, ignition lock, headlight dimmer, and magnetic inspection lamp.

Cylinders are light castings. The L-head design of cylinders is a departure from previous Mitchell practice. This permits all the valves to be placed on one side and to be driven by a single camshaft. Pair casting of the cylinders permits neatness of cover placing and accessibility of the valve mechanism.

Pistons are flat-topped, with three eccentric rings. Piston weight has been kept to the lowest possible figure, consistent with strength.

Connecting-rods, like the pistons, are very light and strong, being drop-forged in an I-section from a special analysis steel that is both rigid and tough. The bearings of the piston pins are heavy-duty, dense bronze bushings, which work on hardened steel hollow pins. The bearings are 2 inches long and 1 7-32 inches in diameter. Woodruff keys keep the pins from turning and from shifting endwise by disk-like brass protectors interposed between their ends and the walls of the cylinders. As these are not attached in any way to the pistons, unequal expansion between the cast iron and the steel cannot cause distortion and wear of the pistons. Connecting-rod bearings are 2 1-8 inches in diameter and 2 3-8 inches long.

All Moving Parts Carefully Balanced

Special care is taken in the balancing of the reciprocating parts, so that there will be no vibration at high motor speeds. As each motor is assembled, the various reciprocating parts are paired off and finished to a balance that is exact.

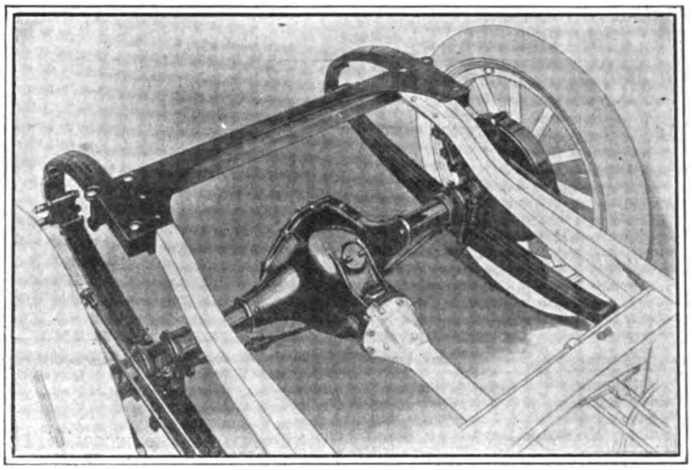
The three bearings of the crankshaft are 2 1-8 inches in diameter. The bearing at the flywheel is 4 inches long, the others being 2 3-8 inches in length. All bearings are wet ground to finish, while permanent alignment and smooth running are insured by the stiffness of the aluminum crankcase which is obtained by special webs. The crankshaft is offset 1 inch from the center line of the cylinders.

Crankcases are of the barrel type without a parting on the bearing line, so that a pressed sheet-steel undercover, in which the oil troughs for the connecting-rods are formed, can be removed for inspection or adjustment of the bearings without disturbing the crankshaft.

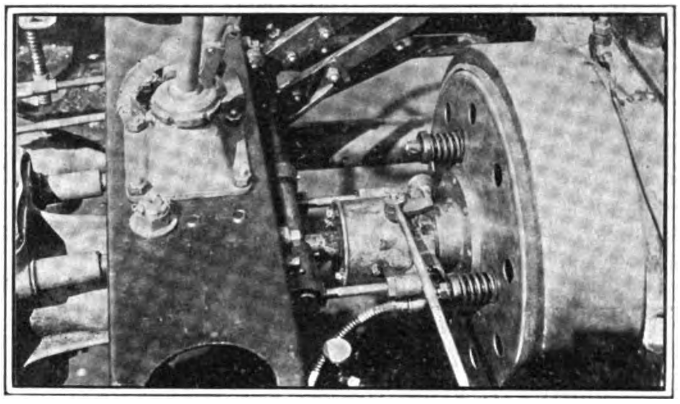
Valves are one-piece alloy steel with hardened and ground stems and are of the non-warping type. They are 1 3-4 inches clear, opening with seats beveled at the angle of 45 degrees. The inlet valve lift is 35-64 inch, and the exhaust 13-32 inch. Valve push rods are single pieces of hardened and ground steel with mushroom heads. The adjustment is effected by simple cap screws with case hardened heads and check-nuts, and the entire valve mechanism is completely inclosed in chambers covered by stamped steel plates, and removable by hand. Valve spring washers are held in place by V-shaped retainers instead of the ordinary key which requires that the valve stems be slotted.

Cams are integral with the camshaft, and the cams and bearing surfaces are deeply carbonized, hardened and ground to form. A pair of steel gears with helical teeth are used for the camshaft drive. These gears have faces 7-8 inch in width.

There are three camshaft bearings, each of which is 1 inch in diameter, the front being 2 9-16 inches long and the others 2 1-4 inches. To permit adjustment for wear and distribution gearing, the front and rear camshaft bearings are supported in eccentric bushings which can be turned to bring the camshaft and this gear closer to the other timing gear.



Rear construction of Mitchell Little Four for 1915



Method of mounting gearshift and emergency levers on crosspiece of frame in Mitchell Little Four. Also adjustment of cone clutch and flexible conduit carrying oil to clutch from motor

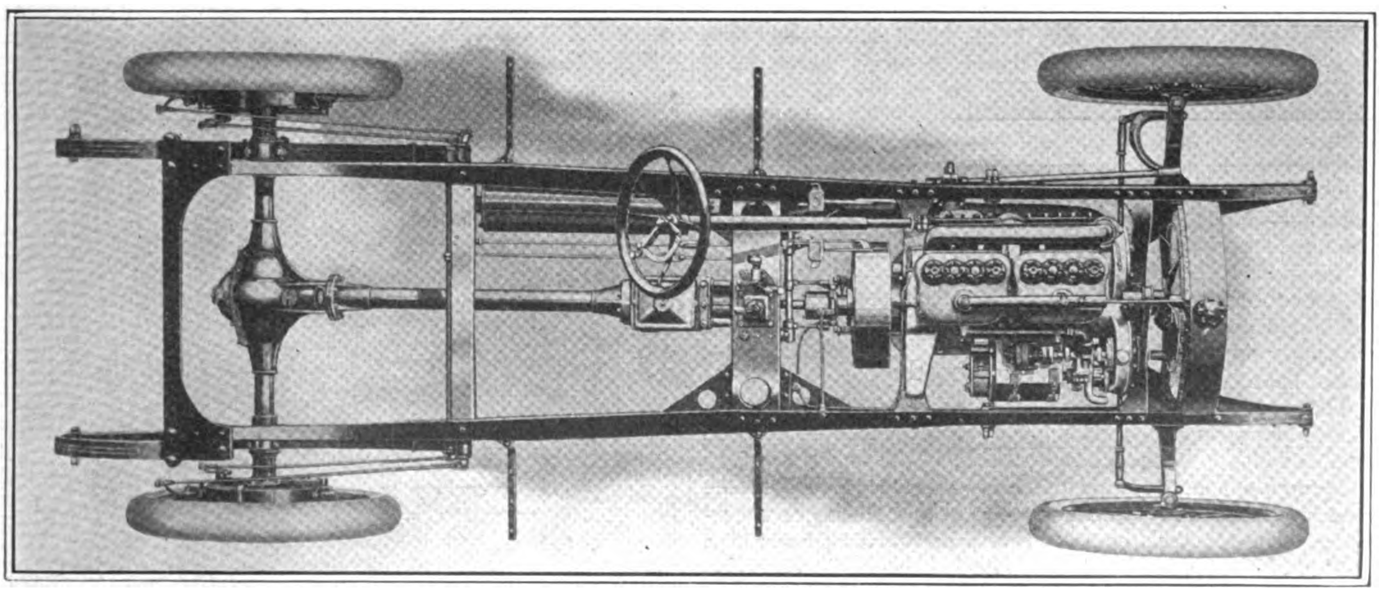
Three-Point Suspension for Motor

Three-point support is employed on the engine, the crankcase resting at the front upon the front cross-member of the frame, while at the rear it is extended into two arms which rest on the side sills of the frame. This three-point suspension avoids distortion of the motor through frame-twisting over rough roads.

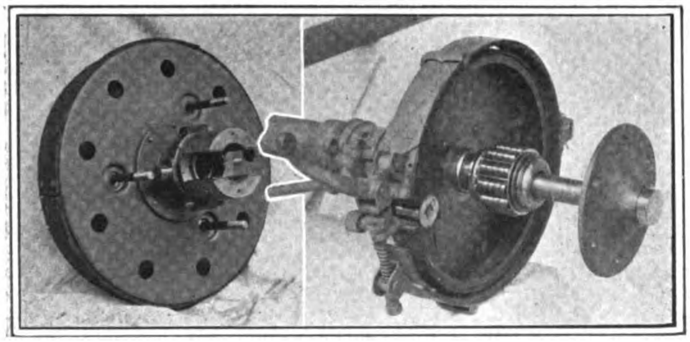
The oil reservoir of the crankcase is formed by the lower cover, which also is used as an inspection plate. The cover is a steel stamping made in two compartments, the lower half is the oil reservoir, and the upper half is fitted with an overflow and troughed for the connecting-rod apron. The system as a whole is a combination circulating splash which has been employed in Mitchell engines for many years.

Starting, lighting and ignition are well taken care of by the Mitchell single electrical system. A single-unit motor generator is carried on the right side of the crankcase and driven by a silent chain completely inclosed in the cast distribution gearcase. The motor generator is hung from trunnions at either end and can be lifted out of its cradle. It is geared at a low driving ratio, only 2.6 turns of the starting motor to one of the crankshaft. The generating function is so arranged that at a car speed of 8 miles per hour the generator is delivering 6 amperes to the storage battery, it is stated. The latter is located on the running board where it does not interfere with getting in or out of the car, but at the same time is handy enough so that the owner will give it the needed attention. Ignition is supplied by battery and generator current through a coil and distributer mounted accessibly upon the engine and driven through a special shaft.

Inlet and exhaust manifolds are both held in the cylinders



Plan view of Mitchell Little Four chassis. Note mounting of Mitchell electrical system at right of motor; also accessible gearbox with hand cover plate



6—Left—Clutch, showing bolts and joint. Right—Interior view of brake drum, showing hub plate of wheel and roller bearing

by a single pair of steel yokes, and to improve the accessibility of the motor the exhaust manifold discharges at the forward end, instead of the rear. This has the additional feature that the objectionable heat under the driver's seat is eliminated, and the hot exhaust is carried directly up to the coolest part of the engine just back of the fan, the air from which cools down the exhaust and assists very much in muffling it without back pressure.

Cooling is by a thin tubular radiator, and the connections to the waterjackets on the cylinders, which are exceptionally ample, are by two outlet tapered manifolds, with heat-proof steam hose between engine and radiator to facilitate this assembly. The radiator is braced by a short rod paralleling the hose to the motor.

Another feature of simplicity is the arrangement of the fan and water pump. The 18-inch, four-bladed fan with a shrouded rim is a one-piece steel stamping. The high-speed centrifugal pump is mounted upon the front end of the fan shaft, where it is accessible close to the radiator and driven without extra mechanism. The fan and pump are driven by a single endless belt with provision for keeping it tight. An important feature of arrangement is the fact that if the pump is permitted to freeze in cold weather nothing worse can happen than momentary slipping of the fan belt.

Propeller Shaft Is Entirely Inclosed

Transmission of power from engine to axle is a continuation of that system employed on older models of Mitchell cars. Its characteristic feature is the division of the power plant into two units, one the motor and its accessories and the clutch, the other the gearset, propeller shaft and rear axle. The important novelty, however, comes in the complete inclosure of the propeller shaft in the torque tube, which is bolted rigidly to the rear axle, while the gearbox is bolted to the front end of the torque tube. The gearbox thus is made a part of the rear axle unit in so far as the perfection of alignment inherent in this construction is concerned, but the addition to the rear axle weight is avoided, and the gearbox merely trunnioned on the frame. Instead of direct trunnion bearings the gearbox is trunnioned by short links so that the thrust of the drive is taken by the springs. A slip joint on the torque tube permits freedom to the twisting action which is inevitable. Suitably placed universal and sliding joints give flexibility between clutch and gearbox.

Final drive is by a bevel pinion and gear, both provided with easy adjustment and with ball thrusts as well as roller radial bearings to carry the loads.

The rear axle is of the floating type, driving shafts are removable without disturbing the wheels which revolve on flexible roller bearings, on the outside of the axle proper.

Springs are half-elliptic in front, 2 inches wide, and the nine levers are 3-16 inch thick. The rear springs are underslung. The construction is of the three-quarter elliptic type and there are ten leaves in the main member 2 1-4 inches in width.

Service and emergency brakes work on pressed-steel wheel-drums, which are 14 inches in diameter with a 2-inch base. The hand brake is internal and the foot brake is external, both faced with non-burnable fabric, and both quickly adjustable without disassembling. The brake adjustment is particularly easy, turnbuckles being provided on the rod and a locked, yet easily operated, adjustment at the drum.

Demountable Rims Are Stock

Demountable rims are stock equipment, and the tires, 34 by 4, are amply large for the weight of the car with its normal load. Either standard or 60-inch tread is optional, and to effect a change from one to the other it is necessary only to interchange the Mitchell patented hub.

The irreversible steering mechanism is constituted of a worm and a full gear on a squared shaft, combining safety with durability, in that there is no sector to run past the worm and lock, while turning the gear into four positions affords four renewals of the wearing surfaces.

Gear and emergency brake levers are in the center of the car to the driver's right, and far enough forward to allow the occupants of the front seats to leave or enter the car easily from either side. The gear lever is of the rocking type, without a gate.

Fuel Tank in the Cowl

All of the indicating devices and instruments are mounted on the cowlboard, back of which, beneath the deep scuttle dash, is the 18-gallon fuel tank, with its filler opening accessibly placed behind the glass front. Also in the cowlboard are the priming pump for starting the 60-mile speedometer; ignition switch, with Yale lock to prevent theft; gasoline gauge; oil gauge, and switches for the lamps. Over the speedometer is a lamp, which pulls out at the end of a flexible cord, long enough to allow inspection of any part of the car.

A unique feature of the Mitchell Little Four is the arrangement of the button which operates the concealed electric horn. The button is placed on the door at the left side in such a position that it can be operated by either the operator's knee or his hand. The difficulty of wiring attending the installation of a button on the swinging door was overcome by using the hinges as a part of the horn wiring, the hinges being insulated from the ground and from each other so the concealed wires simply are brought to the hinge on either side.

The Engineering Digest

Compression as a Factor in Motor Economics — Its Terminology Corrected and Defined

RELATIONS TO SELF-IGNITION AND PISTON STROKE

COMPRESSION of the explosive mixture in an automobile motor is an element apparently so simple that all can aspire to understand how it works. It is therefore misunderstood considerably among motorists at those minor points which most easily escape attention; and these become the main points the moment the question is one of special refinements in motor design. Having discovered that this is the situation and that a slipshod understanding of the matter has spread even to builders of motors and is represented in construction and in the printed explanations of construction, Louis Lacoin, whose work on Construction and Regulation of Internal Combustion Motors is recently being quoted widely, gives a clear exposition of the whole subject, and one well suited for setting popular misconceptions aright and making it easier to explain certain features in motors of advanced design. The influence of the valve-timing on the degree of compression, the existing confusion in the terms used for designating compression and the effect of long-stroke motor design, constitute the principal points to which he calls attention. His presentation is rendered in substance in the following:

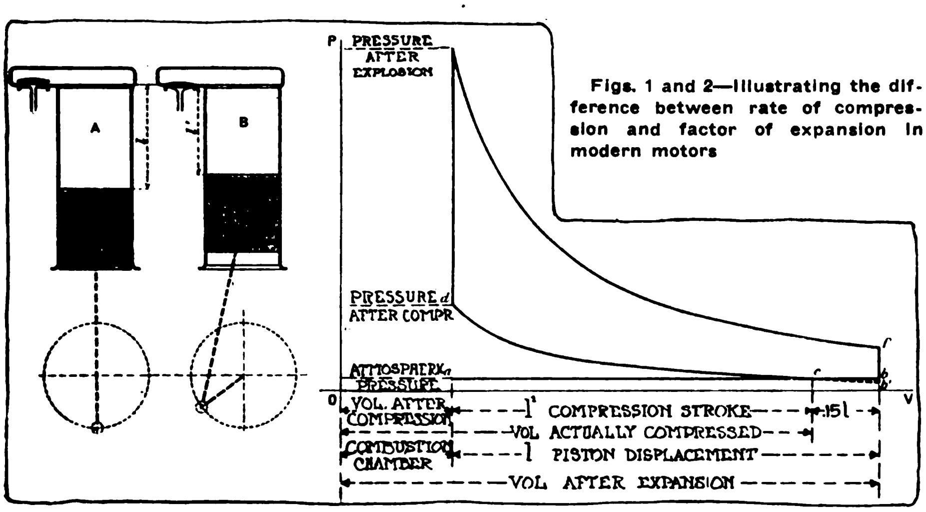
The Troubled Terminology

Strong compression is now looked upon as an indication of high efficiency, and as a rule it is true that the higher the compression is with which a motor can work the better is the motor. It should be added, though, that the real difference between the highest compressions used in practice and the smallest is much more modest than the figures proclaimed by the makers would lead one to suppose. This is due to confusion in terms. When it comes to measuring compression exactly, some makers take the proportion between the volume of the combustion chamber and that of the whole cylinder as a basis while others prefer to designate the compression by the pressure reached in the combustion chamber at the end of the compression stroke. As a matter of fact, though pressure is increased when the volume of the gas is reduced, it is not increased exactly in the same proportion but more rapidly.

In practice both ways of expression are of interest. The proportion in volumes is indispensable for guiding the shop in shaping the combustion chamber to the right volume and capacity, while the pressure determines the forces to which the organs of the motor will be subjected; and the designer must know it for his calculations.

Both expressions are therefore legitimate, and, for that matter, one can be found from the other. But it is necessary to indicate which one is employed, as the difference is great. For an example, suppose the initial volume of gas is 4.25 times larger than the final volume, which is a proportion commonly used. In such a motor the pressure at the end of the compression stroke is 6.56 times its initial value. If then two persons discuss the subject and one claims to compress 6 times and the other admits that he does not exceed 4.25, it may be the second who uses the higher compression, if he speaks of volumes and his friend of pressures.

Merely to specify whether there is question of volumes or pressure is unfortunately not sufficient for disposing of the uncertainty. Each of these terms is subject to certain misundertandings. Continuing to use a motor with a volume proportion of 4.25 as an example, we have, as already mentioned, a pressure at the end of the compression stroke 6.56 times greater than at the beginning. If the latter is taken as the unit, the figure of the compression is consequently just 6.56. But the unit may be considered to be the average pressure of 1 atmosphere, which is equal to the pressure of a column of mercury 760 millimeters high in a barometer and amounts to 1.033 kilogram per square centimeter. On this basis the compression, while still 6.56 times greater than at the beginning of the compression stroke, will be expressed as 6.78, meaning 6.78 kilograms per square centimeter. Finally, by reading the pressure directly by means of a manometer, a figure is obtained which depends upon the actual atmospheric pressure. If the barometer is high—at 785, for example—the initial pressure will be 1.067 kilogram per square centimeter and the final pressure will reach 7 kilograms.



Figs. 1 and 2—Illustrating the difference between rate of compression and factor of expansion in modern motors

Still another mode of expressing the value of the pressure is in common use. It is characterized by leaving out of consideration the initial pressure, on the ground that the compression stroke does not produce it. Accordingly as this initial pressure is now taken as unit, as average atmospheric pressure or as actual atmospheric pressure, three other values must in that case be given as the measurement of the compression; namely, 5.56, 5.75 or 5.93.

At least six different figures may thus be used for indicating the final pressure caused by compressing the same gas mixture in the same motor. For a motor operated with producer-gas six different and higher figures could similarly be employed for measuring exactly the same rate of compression.

When volume is made the basis for the measurement, there is less occasion for confusion. Figs. 1 and 2 show the volumes which enter for consideration. The definition of what is here called the Rate of Compression is absolutely precise. It is the proportion between volume *B*, being the volume existing when all communication between the cylinder and the atmosphere is just cut off, and the smallest volume to which the charge is compressed. If the intake valve were closed at the lower dead center the Rate of Compression would equal the maximum cylinder volume, being the volume of piston displacement plus volume of the combustion chamber, divided by the volume of the combustion chamber, but in all modern motors the volume *B* remaining at the beginning of the compression is in reality smaller than *A* because the inlet valve is not closed till long after the low dead center has been passed. The true Rate of Compression is therefore smaller than the maximum divided by the minimum cylinder contents, though this value is what is frequently taken as the measurement. The proportion of the gross volumes represents on the other hand another important factor in motor economy; namely, the Factor of Expansion for the gases after an explosion.

Prolonged Expansion

Motors in which the Factor of Expansion is greater than the Rate of Compression are known as motors with Prolonged Expansion. To examine the conditions under which such a motor operates, let it be supposed that the inlet valve is closed 45 degrees after the low dead center. The piston has in that case covered about 15 per cent. of its course before the real compression begins. If at this moment the proportion in volumes is still 4.25; that is, if the true Rate of Compression is equal to this figure, the Factor of Expansion is equal to 4.824, which is an appreciably higher figure.

With a delay of the valve opening corresponding tc 25 per cent. of the piston stroke—not yet used in common practice but nowise exaggerated—the Factor of Expansion corresponding to the 4.25 Rate of Compression would even reach the figure 5.333.

The term Volumetric Compression, as used by Letombe, denotes exactly the same that is here understood by Rate of Compression, but the latter term is preferable because it calls for a definition and can therefore not so easily be employed unthinkingly.

Premature Ignition

As has now been seen, the same degree of compression may be denoted by six different figures, when the tension of the gas is made the basis, and by two different figures, if volumes are made the basis; in all eight different modes of telling what a certain compression amounts to are recognized. Of all these only the two denoting the Rate of Compression and the Factor of Expansion are of real interest, as the former represents the element which the chance of premature ignition truly limits and the latter almost exclusively determines the fuel efficiency of the motor. All the pressure figures, on the other hand, may be determined one from the other when the Rate of Compression and the nature of the gas are known.

With the question of terminology settled one can progress to the other question which has so far been discussed rather vaguely; namely, how premature ignition limits the rate of compression.

It is customary to charge premature ignition to the presence in the cylinder of points which have remained at igniting-temperature after the expulsion of the burnt gases. This explanation is only half satisfactory. Especially, such points should certainly be hotter at the beginning of the admission of gas than toward the end of the compression stroke. They should therefore be more liable to ignite the mixture the moment it is introduced than later. They may be the cause of carbureter fires—nothing being more probable—but it is safe to contend that, as a rule, they do not cause premature ignition. If they did, all that would be necessary for making use of very high compressions would be to eliminate them, as shall now be shown.

During the compression the temperature of the gas increases, as well understood. In Diesel motors this increase of their temperature is sufficient to ignite them. Is the condition the same in automobile motors?

Arithmetic of Temperatures

It seems that the reply should be in the negative, as the rates of compression are so different. The Diesel rate exceeds 14; that of automobile motors rarely gets above 4.5. Now, for this rate of compression of 4.5 the proportion in *absolute* temperatures before and after compression is only 1.57. If then, at the end of the admission, the new mixture has the same temperature as the atmosphere, which is a reasonable assumption, and this temperature is 15 degrees centigrade, being 288 (273 plus 15) degrees absolute, the temperature at the end of the compression will be 1.57 times higher than 288, which is 452 degrees absolute or 179 degrees centigrade (452 minus 273).

But the lowest temperature at which a hydrocarbon gas mixture ignites spontaneously is about 450 degrees centigrade. Compression as such is thus far from being sufficient to produce ignition.

The reason for premature ignition must be sought in part in some other factor. There is the actual temperature of the gas mixture at the beginning of compression. It is in reality higher than that of the atmosphere. A certain proportion of burnt gases remains after the previous explosion, still very hot. Its presence raises the average temperature at the end of the induction stroke to 72 degrees centigrade, and the compression carries the total mixture, according to the above manner of calculation, to 269 degrees. This is 90 degrees higher than the figure considered before, but still not sufficient for causing ignition. Suppose, however, that in some quiet and hot corner of the mechanism, in contact with the exhaust valve or its seat, for example, there remains an ever so small portion of explosive mixture which reaches a temperature of 200 degrees centigrade before the compression, then the compression may raise this small portion to the 450 degrees required for spontaneous ignition, whereafter the whole charge will take fire from it. (In fact 200 degrees centigrade equals 473 degrees absolute, which multiplied by 1.57 makes 723 degrees absolute, and this is just the same as 450 degrees centigrade).

It is difficult to prevent the temperature of 200 degrees centigrade from existing at one point or another, and therefore the 4.5 rate of compression is barely practicable.

The Smooth Combustion Chamber

In order to reduce as much as possible the chance for self-ignition it would be necessary to cool the exhaust valves as thoroughly as the rest, which is difficult with the present methods of cooling. It is also needful to shape the combustion chamber so that the gas mixture may continue the course which it follows at its precipitous entrance by way of the admission valve. The whole mass of gas would then take one mean temperature and perhaps a rather high one, but there would be no recess with stagnant air much hotter than the rest. This is the authentic advantage of the semi-spherical combustion chamber.

It has also been established that the free circulation of the incoming mixture and the churning which results from such a movement accelerates the flame propagation started by the spark, producing fuller diagrams, better efficiency.

What Better Cooling Would Do

It is interesting to investigate and see what improvements would follow if some day a more equable cooling of the cylinder were realized. Suppose that the gas mixture at the beginning of the compression were uniformly at a temperature of 122 degrees centigrade. The figure is reasonable, as the unexpelled exhaust gas carries it to 72 degrees and 50 degrees may be added as coming from the heated walls.

These 122 degrees centigrade equal 395 degrees absolute, and the proportion to this of the 723 absolute degrees which stand for the ignition temperature is 1.830 and corresponds, according to the existing tables on the subject, to a permissible rate of compression of 7.5, which is considerably higher than the customary 4.5.

With regard to fuel efficiency the progress would be notable: The theoretical thermic efficiency for the rate of 4.5 is 36.3 per cent.; with a rate of 7.5 it would reach 45.4 per cent., being a gain of 25 per cent.

With regard to power, with the same cylinder dimensions and the same fuel consumption, a motor of 20 horsepower would give 25.

Increased Stroke Taking Place of Compression

All this is still in the realm of speculation. At the present day only very small motors, whose thin cylinder walls admit of a lower interior temperature, can exceed a compression rate of 4.25. But when this rate is adopted and the combustion chamber is established accordingly, there is nothing to hinder an increase of the piston stroke, and thus gaining a large factor of expansion, so long as the inlet valve is forced to remain open long enough. (The author has shown in another article the advantages in fuel economy to be gained by this method.) The efficiency to be obtained in this manner is almost as high as if the compression rate were equal to the factor of expansion. Figures relating to a motor of the dimensions given in Figs. 1 and 2 will show this more plainly.

Without prolonged expansion a compression rate of 4.25 gives only a theoretical thermic efficiency of 35.2 per cent., while a compression rate of 4.824, which would equal the factor of expansion, would carry this efficiency to 37.6 per cent. Knowing that this rate of compression is not practicable we content ourselves with the 4.25 rate and prolong the expansion, as said, giving to this factor instead of to the compression the proportion of 4.824. The efficiency differs very little from what it would be in the other case, reaching 37.5 per cent.

So far as fuel efficiency is concerned, the rate of compression is thus immaterial. It is only the factor of expansion that matters. With regard to the power developed, on the other hand, the influence of the rate of compression is preponderant.

For example—making use of the same figures as before—a motor without prolonged expansion and with a compression of 4.25 gives 20 horsepower with a certain cylinder volume. If the cylinder volume remains unchanged but the rate of compression is increased to 4.824, without prolonging the expansion, the power is raised to 21.35 horsepower. But if the same motor, as it was with the 4.25 compression, is given a factor of expansion of 4.824, the power is reduced, for the same bore and stroke as before, to 18.75 horsepower, because the volume of the explosive mixture has been diminished. It is necessary to lengthen the stroke to get back to the same power, and the motor is then a little heavier, but it consumes less fuel. The increased weight may be offset by the smaller weight of fuel to be carried, at least for long trips, and the economy at all events would be appreciable, as for every 100 francs worth of gasoline used with the shorter stroke to produce a given power, the motor with the longer stroke and the prolonged expansion would require only 93.5 francs worth.

Summarizing: We should aim in our motors at the same time for a high rate of compression, to make them powerful and compact, and for a high factor of expansion, to make them economical, and when we talk about their characteristics we should mention not only their rate of compression but also their factor of expansion, these being data of equal importance and not to be confounded.—From *Omnia*, July 11.

Motors with Steel Cylinders Now Made Economically in Berlin

VERY few steel cylinders are used for automobile motors. Those made in the past have usually been smooth cylinders with welded heads and separate water-jackets. In building up motors with them the cost was high and the production laborious by reason of the many parts to be fitted, and the strength was not always reliable on account of the number of welds used. The Stahl-Motoren Gesellschaft Ernst Jaenisch & Co. of Berlin builds steel motors on a different plan, writes Fritz Klinkenberg, and has done so for some time, developing quite new methods.

The main product is block motors of the approved automobile type, and economy in the production is attained mainly by extensive use of modern factory arrangements and machine tools. The accompanying illustration, Fig. 3, gives views, mainly in section, of one of the types produced, which is a normal four-cylinder block motor, so far as the general design is concerned, with 80-millimeter bore and 130-millimeter stroke, developing 10 German tax-horsepower. The principal dimensions are marked on the cut, representing in some instances the chief point of interest.

(*Continued on page* 241.)

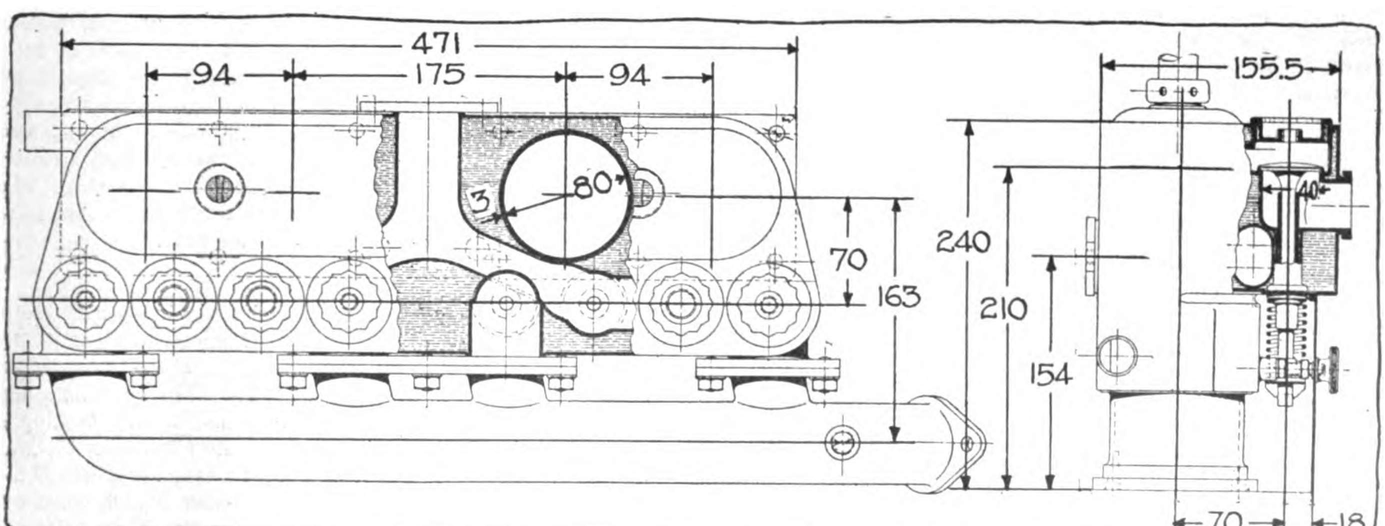


Fig. 3—Views, mostly in section, showing features of Jaenisch steel motors—in this case with cylinders of 80 mm. bore and 130 mm. stroke

Racing Is a Battle of Valve Systems---Knight

The Automobile Engineers' Forum

Inventor of Sleeve-Valve Motor Quotes Performance of Poppet and Non-Poppet Types in Tourist Trophy Race on Isle of Man—Racing Motors Must Reach 3,000 R. P. M. for Modern Racing

COVENTRY, ENG., July 4th—Road racing among automobiles has today resolved itself down largely to a battle of the valving system, namely, the side-poppet valve, the overhead poppet valve and the double-sleeve valve.

The recent 2-day Tourist Trophy race in which three Minerva cars with double-sleeve valves comprised the only team of three to finish in the race, has demonstrated that the sleeve-valve has possibilities in racing which have not been considered to date.

Contrary to the general assumption of would-be motor experts, the double reciprocating sleeves are not the limiting factor for power and speed in a motor, when designed and constructed the same as the high-speed poppet valve motors for speed work alone.

Special Knight Motors for High-Speed Work

The three Minervas which finished the Tourist Trophy race were the first examples of Knight sleeve-valve motors which have been designed especially for high-speed work, these motors having the weight of the reciprocating parts reduced, port area increased, and lubrication methods adequate for racing demands used.

These motors are a slight departure from standard sleeve-valve design in order to increase the port area, and consequently add to the capacity for high speed and power. A bottom exhaust port is added to permit for as much space in the top of the sleeves being used for intake ports.

Further, two eccentric shafts instead of one are employed for reciprocating in the sleeves. There is an eccentric shaft in either side, the shaft on one side operating the four inner sleeves and that on the other side operating the four outer sleeves. The two shafts are used to secure lightness and strength in the sleeves. Steel pistons are used, and pressure lubrication employed.

Smoke Could Have Been Eliminated

The protest against the three Minervas emitting too much smoke during the race emanated from one source only. The majority of the drivers of other cars refused to sign this smoke protest, but signed a remonstrance against it, and the committee, after investgating the matter, rejected the protest. While it is my candid opinion that no high-speed, four-cycle motor can ever be made a commercial success, with a bottom exhaust port because of loss of oil any more than can a four-valve-in-the-head poppet type become practical, yet the objectionable emission of smoke from the three Tourist Trophy Minerva engines could and would have been eliminated for racing purposes had time permitted.

Sixteen 6-Mile Mountain Climbs

The facts remain that in the Isle of Man race are sixteen terrible mountain climbs of over 6 miles each, wherein the motors were turning over at 3,000 revolutions per minute and this required a different adjustment of the lubricating system from that ever contemplated at the Minerva works by the designer. This mountain-climbing work required a maximum of lubricant, and owing to the design of system this maximum could not be varied upon the level and down grades without complete re-designing of the entire mechanism, which, of course, was impossible.

Other cars did not smoke so much at times, nor did they with three exceptions out of nineteen, succeed in surmounting this mountain the necessary sixteen times in succession to a height of over 1,500 feet.

Engine Trouble Put Out Many Cars

Practically all of the poppet valve designs in this race were equipped with four valves per cylinder, and the severity of the race shows how these failed in the early parts of the contest, which was eight laps per day around a circuit of 37.5 miles. In the first lap three cars were eliminated from two teams, namely, two Vauxhalls and one Sunbeam, all with engine trouble. The second lap was just as disastrous, two German Adlers and one of the three Humbers going out with engine trouble. When thirteen laps were over the three Vauxhalls, three Humbers, three Adlers, two Stars, two Sunbeams, one Crossley, one Straker-Squire, and one S. A. V. A. were out, leaving Sunbeam leading, Minervas in second and third, and another Minerva battling for fourth place with a Straker-Squire.

No Adjustment to Two Sleeve Valve Cars

In short, in the field of twenty-two starters, of which nine were of the sixteen-valve-in-the-head construction, but a single one of that new type had withstood the rigors of thirteen successive laps; of the ten side-pocket poppet types, two remained in the race, whereas all three sleeve-valve types remained in the contest. Not a single adjustment of any sort was made to two of the Minerva cars, the bonnets not even being raised before starting on the second day's race. The other Minerva had a broken oil pipe, which compelled it to slow down but not to actually stop in the race.

Fastest Cars Were the Finishers

This Tourist Trophy race contained many interesting facts relative to motor mechanisms. It demonstrated that the fastest cars were not the ones to be eliminated but rather that they were the finishers in the race. The accompanying table shows that Sunbeam I was the fastest car, making a circuit at the average 59.3 miles per hour; Minerva III was second fastest, Minerva I third fastest, etc. In a word, the fastest cars, with the exception of Sunbeam III, finished the race in about the order of their capacity for speed, whereas, many might argue that the fastest cars would suffer more from break-downs or accidents than those which covered the course at a materially lower rate of speed.

Motors Must Make 3,000 R.P.M.

An inspection of the designs of the motors in the recent French Grand Prix race, as well as those in the Tourist Trophy race, will reveal the limits of efficiency of present engine construction. Engines capable only of under 3,000 revolutions per minute stand no chance whatever in first-class competitions today. No motor, with large bore, has any chance of standing up under the severe heat and tremendous piston travel of these high speeds. Ball bearings are being employed generally in crankshafts with as much view to eliminating bearing troubles as reducing friction, but the question of the operation of valves at high speed is coming prominently to the front, and receiving principal attention.

Overhead Valves Mean Lifting Cylinder for Trouble

No designer of a poppet valve motor today would think of bringing forward to compete for speed any motor with other than overhead valve construction, with the accompanying spherical combustion chamber, for the reason that the limit of valve area of the side pocket type has been reached, and that construction is completely abandoned for racing, the same as side chain drive for the road wheels in a passenger car.

But the overhead valve racing design introduces a most disturbing uncertainty and many complications aggravated by the tremendous stresses placed upon it by the enormous speed and pressures met with. The breaking of one of the sixteen valves in the valve-in-the-head construction means the elimination of the car as the cylinder must be lifted in order to replace a valve. The cylinder must be raised to grind any of the sixteen valves, and the best designers can only meet this argument by promising to make the valves unbreakable and so that they will require but little grinding.

Table of the Tourist Trophy Race Held on the Isle of Man, Showing Record of Each Car and Difficult Character of Course

Car	Number of Circuits	Fastest Circuit, Time	Fastest Circuit, m.p.h.	Total Time
		Min. Sec.		Hr. Min. Sec.
Sunbeam I	16	37:55	59:3	10:37:49
Minerva III	16	38:18	58:7	10:57:38 1-5
Minerva I	16	39:10	57:42	11:40:44 3-5
Sunbeam III	12	39:15	57:30	Retired
Straker-Squire I	16	39:50	56:5	11:22:50 1-2
Minerva II	16	40:27	55:58	11:22:20
Straker-Squire II	9	41:12	54:00	Retired
Humber III	13	41:51	53:88	Retired
Star I	6	42:31	52:92	Retired
Vauxhall I	12	43:2	51:96	Retired
Star II	4	43:21	51:72	Retired
Humber I	10	43:24	51:68	Retired
Adler III	10	43:39	51:54	Retired
Crossley	10	44:7	50:94	Retired
S.A.V.A	2	44:48	50:28	Retired
D.F.P.	16	45:2	50:C0	12:24:15
Adler II	1	46:38	49:20	Retired
Humber II	1	46:47	49:00	Retired
Adler I	1	50:22	47:84	Retired

Stirrup Construction Uncertain

The use of the stirrup construction, whereby springs are eliminated, and the poppet valve is mechanically opened and closed by cam action, in order to get speeds of 3,000 revolutions per minute seems to introduce complications and on the surface it looks as if the remedy is worse than the disease.—CHARLES Y. KNIGHT.

Decisions of the Courts—Son Driving Car

By George F. Kaiser

NEW York Appellate Division hands down decision holding that a motor car owner is not liable when an accident occurs while the car is being driven by a person not acting for him.

An automobile, which was being driven by a 24-year-old son of the owner, ran down a man who was waiting for a surface car in a public street. The latter, having been somewhat severely injured, brought suit against the father for damages. It came out on the trial that the son lived with his family and that the automobile was used as a family car by the whole family. The son, however, was the only one who drove it, acting as a chauffeur for his father, or any other member of the family who wished to go out in the car. In addition to this, his father had given him the privilege of using the car on his own account whenever he so desired. At the time of the accident the son, using this privilege, had taken the car out and was driving a party of friends about town.

The Court held that, as the son was neither acting expressly or constructively as his father's agent at the time of the accident, and the car was not engaged in the father's use or service, the injured party's case should be dismissed; this, however, without prejudice to his right to sue the son.—*Heisenbuttel v. Meagher*, 147 *N. Y. Sup.* (*New York*) 1087.

Should Pass on Right

Pennsylvania Court holds that, under ordinary circumstances, a motorist should pass on the right of a vehicle or pedestrian coming in the opposite direction.

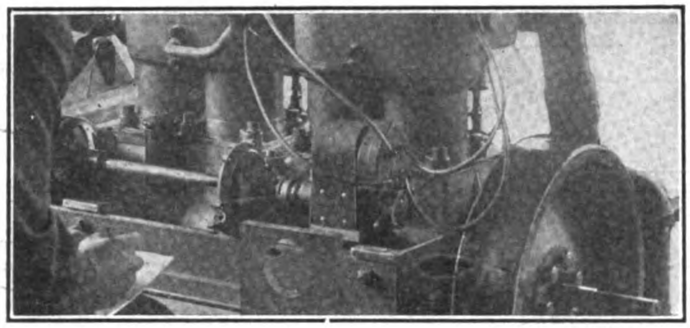
A motorcyclist who was struck and injured in a collision with an automobile while going west on the north side of Walnut street in Philadelphia sued the owner of the car for his injuries and succeeded in recovering judgment against the woman who owned the car, the Court holding that the chauffeur should have passed to the right instead of swerving over to the left of the street.

The chauffeur contended that a team was coming at a "terrible rate"; that he thought it was a runaway and was only trying to avoid a collision when he turned to the left side. The witnesses for the motorcyclist however stated that there was no team present at the time of the accident and the jury, adopting this view, found for him.—*Hazzard vs. Carstairs*, 90 *Atl.* 566.

Automobiles Not Liable to Tax

In a recent case in Idaho it was held that the State Legislature had the right to exempt motor vehicles from taxes by reason of the provision in the State's Constitution which gave them the power to exempt from taxes from time to time in any cases where such a procedure might seem necessary and just.

In this case a resident of Ada County petitioned for a mandate to compel the County Assessor and the Board of County Commissioners of that County to assess all motor vehicles that had escaped the 1913 tax under the Highway Commission Act. The petitioner was beaten, however, for the Court held that it was within the power of the Legislature to exempt automobiles, as there was a provision that registration fees of motor vehicles was to be in lieu of all taxes, general or local, it was only just to so exempt them.—*Achenbach vs. Kinkaid*, 140 *Pac.* (*Idaho*) 529.



The Rostrum

Thinks Two-Cycle Motors Are Passé

EDITOR THE AUTOMOBILE:—For some time I have been reading in the Rostrum the letters of people who are interested in the two-stroke cycle motor. It seems to me about time that some one else took a hand in the discussion.

Why should any one who has the benefit of modern experience and modern engineering progress wish to revert to the early days of the industry when the car was fortunate if it could cover 5 or 10 miles without breaking down?

Of course I don't say that all two-cycle engines are afflicted with this sort of trouble, but when the four-cycle type has attained its present development, with its smooth running qualities and even torque distribution, I cannot see why anyone should want to experience the sensations which I had when I was the fond (?) owner of an old Elmore which with its overlapping explosions, missing fire and ill-smelling exhaust used to haunt my waking hours and, like Macbeth, murder sleep.

Of course the principle of the two-cycle is very attractive, the simplification of parts, the absence of valves and several other factors render it of continued interest of those of an experimental turn of mind, but for the practical automobilist, it seems to me that it is foolish to waste time worrying about this type of construction. There are plenty of other things around an automobile that can be more readily improved upon and which the average car owner would be more likely to stand a chance of improving than this particular department of internal combustion engine construction.

If I am not sensible in putting forward these views on the subject I would like to hear from other motorists and perhaps from some of our engineers who are partial to motors of the two-cycle variety.

New York City. E. R. CRILLEY.

Holding Delicate Parts in a Vise

Editor THE AUTOMOBILE:—A mistake that a great many amateur automobile repairers make when working on a finished automobile part is to clamp the piece directly in a vise without any means of protection.

The sketch, Fig. 2, shows how a piston pin, for instance, should be held in order that the pin will retain its perfect original roundness. Place the pin between two blocks of soft pine, preferably, if wood is available. Any kind of wood is better than no wood at all. In fact almost any soft material may be used such as copper, lead, leather, and even a great many thicknesses of cloth. Remember that the jaws of a vise are hard.

This is about the best way to hold a threaded piece without ruining the threads.

Lead Keys for Light Work

Fig. 1 illustrates a carbureter lever that was originally made without a key or keyway, clamping means being provided by use of a split boss and screw as indicated. However, through carelessness one of the split projections was broken off as shown, rendering the lever useless. The lever was made good again by filing a keyway in the lever boss and chipping and filing a similar one in the shaft. The keyway thus made was a trifle larger than a piece of ordinary soldering wire, the latter being used for making the key. This was done by cutting off short pieces of solder and ramming them into the keyway "cold" by use of the tang of a file.

The lever is solidly fastened and there is little danger of it slipping off. The solder can be rammed in to almost any degree of tightness.

New York City. W. F. SCHAPHORST.

Some Starters for Ford Cars

Editor THE AUTOMOBILE:—Can you put me in communication with the maker of reliable self starter for a Ford car? I am in the market for a starter, electric preferred. Speaking candidly to you, I cannot walk, therefore drive my car with hand levers, and for this reason I am in need of a reliable self-starter. Will you advise if you can get a line on

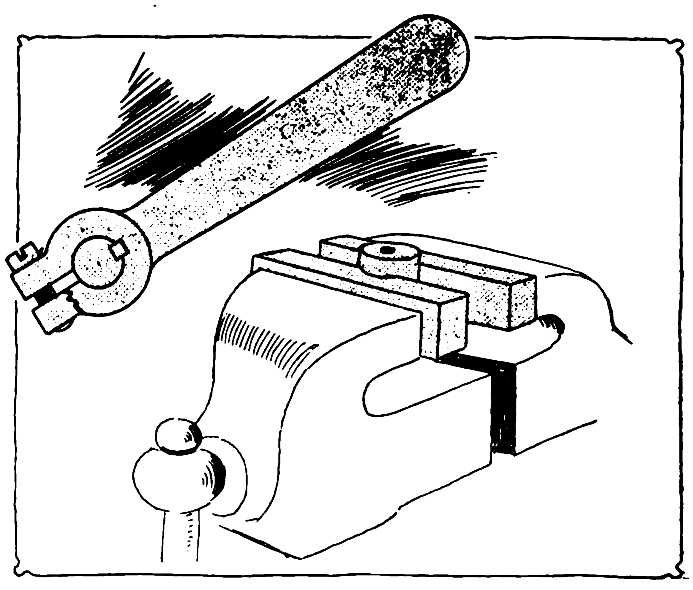


Fig. 1—Upper—Clamping a carbureter lever with a split boss and screw. Fig. 2—Lower—Using wooden blocks for holding delicate parts in a vise

the Detroit Electric Company starter called Deaco, and if said starter is put out by a concern that is reliable?

Warwick, N. Y. E. P. MAIDMENT.

—The Deaco is manufactured by the Detroit Electric Appliance Co., Detroit, Mich. As stated elsewhere in this issue, we cannot pass upon the merits of any given device.

Below is a list of the various types of starters made especially for Ford Cars together with the names and the addresses of the companies. The mechanical types, in which muscular power is required, have been omitted because this kind would be of no use to you.

Electrical starting systems similar to those employed on larger cars offer the advantage that the electric lighting of the car is obtained by the same system. Some of these systems have been produced in a form specially adapted for installation on the Ford.

Another type of engine starter is the compressed-air type in which the motor is made to store air under pressure in a tank, the air then being released into an air motor when it is desired to start. One of the advantages is that the compressed air thus provided always is at hand for tire inflation.

Starters of the spring type differ from those just described in that the engine itself stores up the power by which it subsequently is cranked. The rotation of the crankshaft in ordinary running winds up a spring which when released by the pressure of a foot button whirls the engine over rapidly. Such an one is the Ever Ready, made by the American Ever Ready Co., New York. It is attached in front of the radiator and takes the place of the starting crank. It is about the size of a headlight and looks like a headlight reversed.

A starter of the spring type is the Gardner, made by the Gardner Engine Starter Co., Chicago. This one is inserted in the transmission system, and the only part visible is the foot button which operates it. It is so arranged that after the start connections automatically are established for rewinding the spring.

Another starter designed for the Ford is the Knapp, a compression spring starter operated by a pedal which turns the engine direct on the magneto. The Knapp starter costs $25.00 and weighs less than 50 pounds. It is manufactured and sold by the Fawkes Auto Co., Minneapolis, Minn.

The Boston mechanical starter of the Automatic Appliance Co., Boston, Mass., is of the chain-pull type. It is so arranged that none of the apparatus is visible except the handle on the dash. C. E. Bridges, Chicago, has a pull-type starter which is installed easily. It sells for $12. The Perfection Auto Starter, Denver, Colo., has a pull-type starter operated by a pedal. Attachment is easy and the outfit is listed at $25.

Of the electric systems, one is the Fisher, made by the Fisher Electrical Works, Detroit, Mich. The equipment consists of a motor and generator mounted one above the other in a single housing, a storage battery box, wires, lighting and starting switches, ammeter, chain and sprockets and reflectors for the headlights. The claim is made for this outfit that it can be applied by the owner of the car and that without drilling a hole or altering any part of the engine. With a slight change in the starting crank it may be left in position.

One of the first concerns to market an electric cranking and lighting system for Ford cars is the Northeast Electric Co., Rochester, N. Y. The Ford apparatus consists of a motor-generator driven by silent chain from the crankshaft of the motor, suitable accessories such as brackets and fastenings, and a battery. In operation, pressure on a pedal causes the Ford engine to start, because the battery current flows through the cranking motor. When the engine picks up its cycle the pedal is released and the generator comes into play charging the battery.

A simple starting and lighting system for Ford cars is manufactured by the Detroit Electric Appliance Co., Detroit, Mich., which the owner of the car may himself install. A motor-generator driven by silent chain supplies the current when the car is operating at sufficient speed, but at low speeds, or when the motor is stopped, a battery attached to the running board furnishes the current. Pressure of the heel upon a pedal sends current from the battery to the starting motor, which in turn cranks the engine. All the terminals are marked in some way and the wires cut to exact size, so that the installation is a simple matter.

The Leece-Neville Co., Cleveland, O., has produced an electric starting and lighting system for Fords, designed for quick installation. The Gray & Davis Co. has announced a starting-lighting system for this car, which is very compact and can be installed in a few hours by any garageman. The feature of the system is that the Edison storage battery is used, by which means a lighter and more compact battery is obtained than is possible with the more common lead plates.

The Kellogg Mfg. Co., Rochester, N. Y., has brought out the Kellogg Air-Ford starter, with simplicity, efficiency and moderate cost as the aim. The Kellogg-starter is built under the Durno pattern. A four-cylinder Kellogg air pump is mounted conveniently upon the motor and driven by chain from a gear on the forward end of the crankshaft; this stores air in the storage tank, which upon the pressure of a button on the floor board is released to a starting cylinder which drives backward a piston in that cylinder, pulling a chain over a sprocket on the crankshaft.

The motor is turned so fast that one impulse turns it over several times. A spring returns the drum and prepares the starter for a second application of power. The outfit is supplied ready for attachment on the Ford at $70.

The Gemmer-Detroit Starter Co., Detroit, Mich., has a new air-starter system in which a single instrument performs the function of both the air compressor and the air motor. This combined motor-compressor is in reality a four-cylinder air pump mounted on the engine and driven from the timing gears. When running as a pump it stores up compressed air in a special tank which may be released either for tire inflation or for engine cranking. When air from the storage tank is admitted to the combination unit it runs as an air motor connected to the crankshaft of the engine by gears. Thus it spins the crankshaft at a speed of about 200 revolutions per minute. The total weight of the system is about

Fig. 2—Fireless cooker used as an extra seat

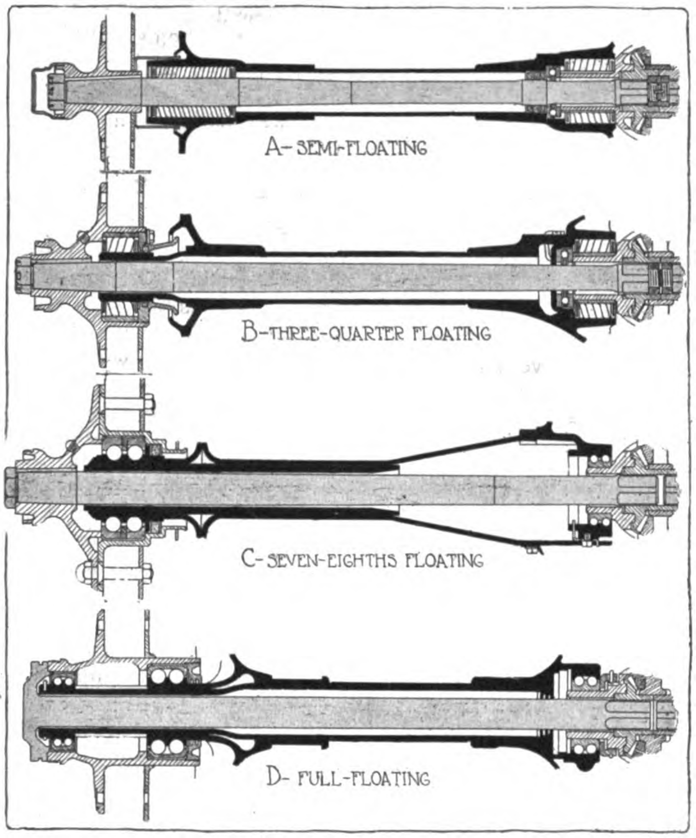

Fig. 3—Weston-Mott rear axle constructions, A is semi-floating, B is three-quarters, C is seven-eighths and D full-floating

35 pounds. A special installation has been developed for Ford cars, designed with a view to quick application.

Fireless Cooker for Seat

Editor THE AUTOMOBILE:—Fig. 2 shows an automobile which is equipped with a fireless cooker, which is used as an emergency seat for carrying extra passengers.

The owner of the car, who resides in Toledo, O., has a summer home at Lakeside, 50 miles distant. At the time of leaving home the cooker is pressed into service and upon arriving at the end of the route, the chicken or roast is ready for serving. To the owner and his family this cooker has been one of the most essential parts of the touring equipment. The cooker, having been made with an upholstered top, can be used as an extra seat.

Port Clinton, O. LOUIS P. WARNER.

Discard Radius Rods for Simplicity

Editor THE AUTOMOBILE:—1—Kindly state in your columns why so many manufacturers are using the rear springs to take the final drive through or why they are doing away with radius rods.

2—Give the pros and cons of the semi-floating and full-floating type axles.

New Matamoras, O. F. N. S.

—1—The principal reason for discarding the radius rods is simplicity. It is obvious that when the drive is taken directly by the springs that the manufacturer has saved on the cost of production and also reduced the number of wearing parts. Many manufacturers believe that the drive can be just as successfully transmitted through the springs as through radius rods, but as both constructions are widely used it is difficult to say which is better.

2—Below are two letters, one from the Weston-Mott Co., and the other from the Packard Motor Car Co., showing the advantages of semi-floating and full-floating axles. Last week the views of the Pierce-Arrow Motor Car Co. on this subject were given in a letter entitled, Pierce Prefers Semi-Floating Axle.

F. A. Bower, Chief Engineer of the Weston-Mott Co., says, "Fig. 3 shows the four types of axles, the semi-floating, three-quarter, seven-eighths and full-floating types, these being designated by the letters A, B, C, D, respectively. While the blueprint is explanatory in itself, we will try to show in detail the advantages of the three-quarter and full-floating types over the semi-floating.

"On semi-floating axles, the entire weight of the car comes directly on the axle shaft, which in time has a tendency to cause this shaft to crystallize and break. This condition is overcome, however, by making the shaft exceptionally strong to withstand crystallization.

"The three-quarter floating type, has all the advantages of the semi-floating on account of fastening the shaft at center of axle, but instead of taking the load on the shaft, it takes load on the axle housing. Therefore, the only strain thrown on the axle shaft on the three-quarter-floating type is the torque required to turn the wheels, and the shaft also assists to steady the wheel. This type is preferable to the semi-floating on this account, as any possibilities of shaft troubles are done away with.

"C shows the Weston-Mott single bearing hub full-floating type. On this type the shaft can be removed without jacking up car and it has all the advantages of the full-floating, shown in D, with the exception that the shaft helps to steady the wheel. The advantages of the type shown at C over the type shown at B is that the construction of C permits removal of the shaft. In B the hub and wheel only can be removed, but not the shaft.

"D shows the standard full-floating type of axle. This means that the only strain taken on the shaft is the torque required to turn the wheel. This shaft can also be removed by simply taking off the hub cap and pulling it out.

"Regarding the advantage of bolting the shaft at center of the axle over the type which slides into an intermediate hub—it may be stated that when a shaft is bolted, it is practically assured of always setting tight, but when the shaft slides into the hub, after continuous wear, it may develop a slight looseness. However, this is not a serious disadvantage, as this type of axle has been made for a considerable number of years and complaints as to wearing of shaft and causing looseness are very few. In fact, they are not enough to cause the slightest worry."

Semi-Floating Axle Lighter—Packard

Russel Huff, consulting engineer of the Packard Motor Car Co., in comparing the semi- and full-floating types states:

"The question of why the Packard company uses the semi-floating rear axle construction instead of the full-floating construction is oftentimes put up to Packard salesmen to explain. The following are some of the more important advantages and reasons why we use the semi-floating type of rear axle construction instead of the full-floating type on our touring cars:

"1—Weight—The full-floating type of rear axle design is heavier than the semi-floating type.

"2—Accessibility—In the Packard construction, the rear wheels can be removed much more easily and quickly than with the full-floating construction. The same thing that makes the wheel in full-floating construction difficult to remove, also makes it difficult to hold grease in this construction.

"3—Structural Points—The full-floating rear axle construction calls for the rear wheels to be mounted directly on the extension of the rear axle housing. In studying the two types, we anticipated serious trouble in cases where a car skidded into curbstones, or met with other similar accidents, where the force was sufficient to break the wheel and bend the supporting member. In recent years we have seen several cases where the tubular extension, which carries the rear wheel in the full-floating type, has been bent by ordinary skidding into curbstones, and which called for an entire new rear axle housing simply because one end of it was slightly bent. Repairs for a slight accident of this kind with this construction might become very expensive; whereas in the semi-floating type of construction, like the Packard, nothing but the straight driving axle would be bent, and this can be replaced without great expense.

"4—Service Expense—We have also seen these tubular extensions in the full-floating construction broken off by crystallization from overload or ordinary fatigue, and here again the expense for a new housing is many times greater than would be the expense for a new axle which might break for the same reason.

"5—Bearings—The rear wheels in the full-floating construction are usually carried on two anti-friction bearings placed rather close together on the tubular housing extension. These bearings are subject to the same wear and tear as the front wheel bearings, and if not kept in close adjustment, produce a serious wobble to the wheels, which in time may cause the breakage of a driving axle. The semi-floating construction has a massive single bearing supporting the wheel near the hub, and a bearing in the differential in the center of the housing for keeping the axle in alignment.

"6—Driving Axles—The average full-floating type of rear axle now on the market does not have proper provision for securing the axle in driving position. We have seen many cases where the hub cap, which is designated to hold the axle in position, has been lost and has allowed the axle to work out of engagement with its driving members. It is no unusual sight to see cases on our streets where the driving axles are held in position by strings and wires because the hub cap has been lost.

"7—Use of Wire Wheels—It is almost impossible to get a good wire wheel installation on a full-floating rear axle. In order to accomplish it at all, it is necessary to have the driving clutches and the rear wheel bearings very small in diameter. If ample diameters, such as are standard on some of the well-known makes of cars using full-floating construction, were used, the wire wheel hub diameter necessary to slide over these would become too large to be practical for interchangeability between the front and rear wheels.

"8—Extra Universal Joints Required—The full-floating driving axle, to be practical and safe, should drive the rear wheel through some form of universal joint. All universal joints in an automobile eventually chafe and wear and produce a serious cluck and jerk in the transmission line, due to the increased lost motion of the worn parts. It has been the Packard idea from the beginning to reduce the number of universal joints in the transmission line to a minimum. This is one reason why we have the rear axle transmission and the semi-floating type of rear axle drive.

"This semi-floating construction is also used by the Pierce in this country, and the Renault and many others abroad."

Wants Information on Beach Records

Editor THE AUTOMOBILE:—To settle a wager will you please publish the records for miles made at Ormond Beach by Marriott in a steam car, and those made later by Burman and Oldfield with a Benz. Also the fastest time officially or unofficially made by Duray with a Fiat at Ostend. I think I have seen somewhere in print that in one of his trials he made a speed of 150 miles per hour.

Gibson, N. C. SUBSCRIBER.

—The fastest time made at Ormond for 2 miles was that of the Blitzen Benz driven by Burman on April 23, 1911. when he covered that distance in 51.28. Oldfield in the same car made that distance in 55.87. The Stanley steamer driven by Marriott made 2 miles in 59 3-5 seconds in 1906.

On December 16, 1914, Arthur Duray, in a 300-horsepower Fiat, attained a speed of 142 miles an hour in an attempt to secure the world's flying kilometer record. The attempt on this record was carried out on the shore road near Ostend.

Road Turns Marked with L or R

Editor THE AUTOMOBILE:—I have noticed several roads around South Bend, Ind., and have also followed their route to Albany, N. Y., and also up into Wisconsin. The turns of the route are marked with a large L or R as the turn may be to the left or right. The route and markings has appealed to me very much and I would like to know who is behind it and also who did the marking.

South Bend, Ind. CHAS. H. FRAZIER.

—The National Trail Blazing Assn. of St. Paul, Minn., is the association behind the marking of these routes.

Water Leaks from Pump Cups

Editor THE AUTOMOBILE:—1—Will you please tell me how to prevent water leaking out of the grease cups at either side of the water pump?

2—The spark lever on my car is very hard to turn, especially when the motor is hot. Where do you think the trouble is and how can I remedy it?

3—What is the best way to keep tires from sticking to the rims?

Albany, N. Y. J. H. H.

—1—You are using too light a grease in these grease cups with the result that when the motor gets warm the grease becomes very fluid and allows the water to leak. In hot weather you should use a heavy grease, probably the hardest that you can buy will be the most satisfactory. However, as soon as cold weather sets in substitute a lighter grease.

2—While this stiffness may be in any of the joints of the linkage operated by the spark lever, it is most likely that the breaker box is too tight a fit, so that when the motor becomes heated the expansion of the part on which it fits causes it to stick.

Disconnect the breaker box from the linkage and note whether it moves freely. If it does not, remove it and rub the interior surface with emery paper until enough material has been removed to allow it to work freely.

3—In order to keep the tires from sticking to the rims it is necessary to prevent the rusting of the rim and this is most satisfactorily accomplished by the use of flake graphite. The graphite is mixed into a creamy paste by adding a small percentage of gasoline. This is then applied to the rims the same as ordinary paint. The gasoline evaporates and leaves the graphite which not only prevents rusting to a large extent but holds the bead of the tire away from the metal of the rim.

Rubber versus Rails

IT is significant that it is the president of one of the largest railway systems in the Middle West who has pointed out the importance which the automobile has attained in Iowa, which is also typical of its status in the other States of the Union.

He states that more than 100,000 automobiles are licensed in Iowa and that the amount of money expended on them by the people annually is in excess of that spent for railroad travel inside the State. The automobile and public roads questions, according to this railroad president, have become more important to the public than the railroad question. People are more concerned with the price of rubber than with that of steel rails, more concerned with the cost of gasoline than with that of coal, more interested in having perfect highways than perfect railways.

But what is more significant, this official looks for an element of consolation in this state of affairs and finds it. He points out that "the man who is concerned with many things is never narrow minded; the citizen who realizes the cost of maintaining and operating an automobile, the cost of perfect highways and their upkeep, also realizes what it means to maintain and operate a railroad; he will not deal broadly with one and narrowly with the other." Thus the development of one will aid the other.

Truck Users in Line

NOW that there is assured a convention of motor truck manufacturers in conjunction with motor truck dealers, why not go one step farther and invite the motor truck users to participate?

The successful operation of a truck depends on the manufacturer, the dealer and the owner. If one is a failure, the others can not reach that degree of success which they should. The interests of the maker and the dealer are very closely allied, but the field of the owner is equally close to them. Successful truck operation interests all three to such an extent that it might be advisable to consider having a day given over to the subject of truck owners' affairs.

There is a precedent for this in our national road organizations, which divide their sessions and give one day to road users, who take up those problems of first interest to them.

Truck Owners' Day would be a red letter one in a motor truck convention. The owner has many questions he would like to ask the truck maker and the truck dealer. There are many problems on so-called service that would be well threshed out if the owner, the dealer and the maker were in the same room at the same time and discussing this all-important subject. The owner could give the maker not a few points of interest and also give some facts of first-class value to the dealer. The owner would benefit because he would receive many criticisms and suggestions where designs could be improved and on the other hand the owner would realise the difficulties encountered by the truck manufacturer, and would not make unreasonable demands.

Then, there are problems in which all three are concerned. A union meeting of these three factors in the truck regime would solve many questions on driver difficulties, tire mileage, overloading, overspeeding, time payments, etc., that are bothering all parties and will continue to bother them until some get-together meeting of this kind takes place.

The truck owners' day could be fathered by some organization outside of the makers and dealers, preferably some club that would faithfully represent their interests. One thing is certain, namely, that if a score or more representatives of truck owners could be gotten to such a convention much good would result. It would be one of the best possible things for the truck interest. It would breed more confidence between owner and maker. Today there is too much doubt and too much uncertainty.

The owner doubts the work of the maker. He distrusts the vehicle, the guarantee and the service assurances. On the other hand the maker imagines the owner is attempting to destroy the truck as rapidly as possible. A little getting together will bring the maker and the owner on common ground. One will see that the other is human, and vice versa. Common interests will be discovered. The net result will be a better understanding, and the engendering of a spirit of unity for the motor truck industry that will be a most valuable asset to it. Let us see if the owner cannot be interested. A dozen owners might represent over 1,000 trucks.

239,902 Cars From 25 Detroit Plants in 6 Months

Output Is 77,902 Without Ford Production—1,258 Commercial Vehicles Built—Fifteen Make Over 1,000 Cars

DETROIT, MICH., July 27—According to information furnished by 25 manufacturers of automobiles in this city they have built during the first 6 months of 1914, that is between January 1 and June 30, a total of 239,902 cars.

Leaving out of these statistics the 162,000 cars made by the Ford Motor Company, there remains an output of 77,902 cars for the other 24 manufacturers.

Of the 25 concerns located in the Michigan automobile metropolis from whom data was obtained, 17 make pleasure vehicles and some of them also commercial vehicles; 5 are exclusive manufacturers of commercial cars and 3 make electric vehicles.

A total of 237,794 pleasure cars were made by the 17 companies. Not including the 162,000 cars made during the first 6 months of this year by the Ford Motor Company, the total number built by the other 16 manufacturers is 75,794.

The 5 commercial vehicle manufacturers built 1,258 delivery wagons and trucks. The three electric vehicle manufacturers reported having constructed 850 vehicles.

Of the 27 concerns having furnished information, one made more than 150,000 during the first 6 months of this year; 3 made more than 7,500 each; 4 made between 5,000 and 7,500 cars; 6 made between 2,000 and 5,000 cars, 3 made between 1,000 and 2,000 cars and 10 made less than 1,000 cars each.

Europe Is Speed Mad—Heaslet

DETROIT, MICH., July 25—Vice-president and chief engineer J. G. Heaslet of the Studebaker Corp. returned a few days ago from an extensive trip through England, France and Germany, during which he made a close investigation of the trend in automobile construction abroad and the requirements of the foreign market in relation to American export business.

In speaking about his trip Mr. Heaslet said:

"Everyone is familiar with the fact that Europe has far better roads than America. There has been time to build them and the various countries over there are intersected with splendid highways. The result is that the European motor car owner drives at a far higher speed than the American motorist and he keeps his car going at a much greater average pace. Rough roads keep the speed low in America; good roads force it to the top notch in Europe.

"Consequently in Europe with the ultimate power of the engine almost constantly in use the driving parts are continuously subjected to the greatest strain and stress and these conditions are much harder on the car. Our rough roads may develop only rattles because of the bumps and jars; in Europe all the driving parts are put to the severest test and the whole car must prove its strength and durability or fail.

"This is a matter that must be seriously considered in manufacturing cars for European consumption and the ultimate car is the automobile that is capable of taking all types of stress—that will meet all requirements for both Europe and America.

"As soon as American roads are improved as they are in Europe, American and European standards will become more nearly identical, and this result will be more to the advantage of American manufacturers than to those of the old World, as American makers will then be able to build a quality car which more nearly comes up to European ideals and at a price with which foreign manufacturers cannot compete."

P. K. Hexter Brings Out Stepless Bus

NEW YORK CITY, July 28—A stepless double-deck bus seating 38 people has been brought out by P. K. Hexter, New York City. The door is at the right side and the floor is so low that passengers can step, without difficulty, directly from the street into the bus. When the bus stops alongside the curb the floor is practically flush with the sidewalk.

Access to the upper deck, which is open, is had through a stairway that runs back from the side door. The conductor sits directly in front of the door and staircase. Accidents to passengers are largely eliminated because it is impossible to jump on or off the bus until the conductor opens the door. It is a very roomy design.

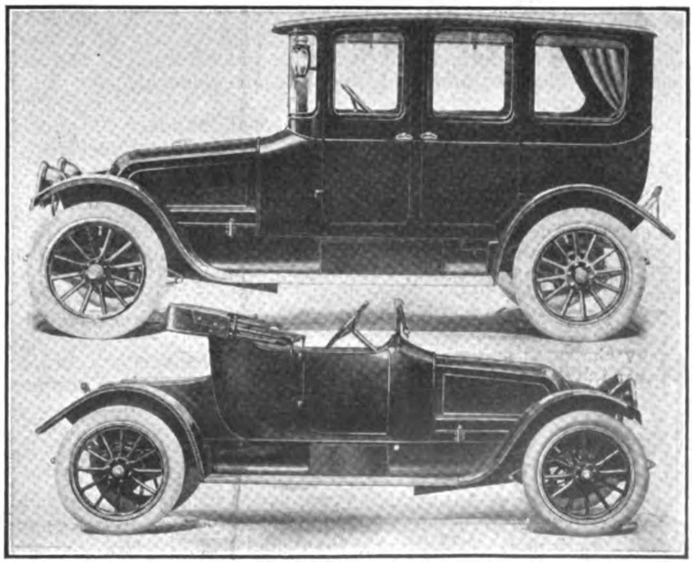
The chassis used is equipped with a 5 by 6-inch motor and the Hexter system of gasoline electric drive which was described in the October 9 issue of THE AUTOMOBILE, page 663. The gasoline motor and generator are mounted at the front while the electric driving motor is at the rear, the drive being transmitted to the axle by a worm gear. With the electrical form of transmission the floor can be placed as low as desired.

New Franklins Lower in Price

SYRACUSE, N. Y., July 27—The most important feature of the announcement of the Series Six-Thirty by the H. H. Franklin Mfg. Co. is a substantial reduction in price. The touring car and roadster are to sell for $150 less, while the reduction on other models has been even more. The prices of the new machines are: Touring car and roadster, $2,150; coupe, $2,600; sedan, $3,000, and Berlin, $3,200.

In the new model the body is larger, the sides of the seats higher and the upholstery is finished off in a roll around the tops of the seats. A shutter effect is used in the front of the hood instead of the old type grill. Goodrich Silvertown cord tires or Goodyear Power Saver tires are now standard equipment. Increased silence has been obtained by using skew bevel gears in the rear axle. The starting and lighting system has been simplified and made lighter and more accessible. The weight, however, remains the same, 2,750 pounds.

NEW YORK CITY, July 28—W. E. Fisk, secretary of the New York State Automobile Assn., and M. Rocomora, manager of the road guide department, have started from Hornell on a pathfinding tour through the state to meet the officers of the local automobile clubs to make final arrangements for the 1914 official tour of the state association, which commences August 31 and continues for over a month. This city is scheduled as one of the stopping points in the official tour of over 3,000 miles.



New Franklin Berlin and roadster models

Chalmers "Light 6" at $1850 —Dealers Vote $50 Raise

Convention of 500 Agents Also Boosts "Master Six" $125 to $2400— Guarantee for Second Hand Cars

DETROIT, MICH., July 25—The most important among the various decisions taken at the recent convention of dealers or representatives of the Chalmers Motor Company, Detroit, was the unanimous approval by the 450 to 500 agents present of the raise in price of the 1915 Chalmers cars, model 26B, the "Light Six" to cost $50 more or $1,850 and model 29, the "Master Six" to cost $125 more than the 1914 models, or $2,400.

This is rather surprising considering that most of the other automobile manufacturers who have announced their 1915 models made a reduction in their prices. "If the men who are to dispose of our output approve of our policy in increasing our prices instead of cutting them, it's a pretty good indication that they believe we are bringing out a car which is fully worth its price," said an official of the Chalmers company. "As we do not sell our cars on a consignment basis, as the dealers buy their supply of cars from us, it is quite natural that they would be the first ones to protest against a raising of the prices if they thought it unjustified. But just the contrary has happened."

Another important decision by the majority of the dealers was that hereafter second hand Chalmers cars will be sold by the dealers with a guarantee, just like new cars. In most cases used cars will be handled entirely separate just as if it were a different business.

The new Chalmers Dealers Service Policy was also adopted by all and will be of the greatest assistance to Chalmers owners and drivers, who will now be able to secure service from any Chalmers dealer in any part of the country, no matter where the owner or driver bought his car. For instance if a motorist bought his Chalmers in New York and is in Des Moines, Ia., requiring special service, he will get it from the local Chalmers agent. The new policy contains the following three clauses, in effect among all Chalmers dealers:

First.—It is our intention to give each and every purchaser of a Chalmers car fair and business-like treatment. Should any customer not receive such treatment, we ask in good faith to be advised.

Second.—We will make all necessary repairs and adjustments, without charge, for one month after delivery of car, provided car has not been tampered with or injured through accident.

Third.—We will install, without charge for labor, any parts that may be replaced as defective by the Chalmers Motor Company, or ourselves, for a period of ninety days after date of delivery of car; after such date, all work will be done in a careful and workmanlike manner and our regular charge made for same.

(Signed) Dealer..............

Many of the officials and dealers at the convention made informal speeches touching upon a great variety of subjects interesting the industry. Here is a list of some of the subjects: "The Automobile Business In General," by Hugh Chalmers, president; "Salesmanship and Advertising Principles," by Lee Owell, assistant general manger; "Manufacturing Methods," by H. H. Pinney, works manager; "Service and Engineering Principles," by Geo. W. Dunham, consulting engineer; "Advertising," by Lee Anderson, manager advertising department; "Selling Cars and Salesmanship," by Lee Counselman, general manager; "The Second Hand Car Problem," by James Levy, Chicago; "Service To Owners," by H. L. Keates, Portland, Oregon; "Following Up Sales Prospects," by Geo. Stove, New York; "Personal Salesmanship," by E. W. Wyckoff, Pittsburgh; "Maintaining Show Rooms," by J. J. Mandary, Rochester, N. Y.; "Educating Salesmen," by C. E. Whittin, Lynn, Mass.; "Covering Territory and Establishing Sub-dealers," by E. C. Anthony, San Francisco; "Service To Owners," by O. L. Weaver, Cleveland.

Haynes Light Six for $1,485

KOKOMO, IND., July 28—The feature of the Haynes line for 1915 will be a light six of 55 horsepower, to sell for $1,485, fully equipped. It will be furnished both in two and five-passenger body styles, will have left hand drive and center control, and will be fitted with the vacuum system of gasoline feed.

In addition to this model the Haynes Automobile Co. is offering a big six rated at 65 brake horsepower and selling for $2,250, and a four developing 48 horsepower and selling for $1,660. The light six is an entirely new model. The electric gearshift will be continued on the big six and the four, but it is not fitted to the light six. Closed bodies are fitted to the big six and the light four.

The weight of the light six, completely equipped, is 2,950 pounds and the wheelbase is 121 inches. A unit power plant with three-point suspension has been adopted and it includes an L-head block motor 3.5 by 5 inches, three-plate clutch and three-speed gearset. A full-floating rear axle is used and the springs are semi-elliptic all around. Artillery wood wheels are found.

New Brasie Co. To Make Cyclecars

MINNEAPOLIS, MINN., July 25—The Brasie Motor Car Co., 2743 Lyndale avenue S., Minneapolis, Minn., is a $100,000 corporation for the manufacture of automobiles and trucks. It takes the place of the former Brasie Motor Truck Co., which manufactured the Twin City truck. In its incorporation the company enlarges its scope and will make a cyclecar pleasure car and cyclecar delivery, as well as a trailer.

J. M. Michaelson, formerly maker of the Minneapolis motorcycle, the Shapiro-Michaelson motorcycle and the Michaelson cyclecar, has associated himself with the Brasies in the new company. As secretary he will have charge of sales and advertising. F. R. Brasie, president and treasurer, will control the purchasing and shop, and Mrs. (E. C.) Brassie is vice-president.

Delivery of trucks has begun, cyclecar deliveries will begin in thirty days and pleasure cars in sixty days. The latter is to be known as the Messenger and the former as the Packet, on the theory that the name should show the purpose of the cars. The car is adapted especially for mercantile men to take orders and collect money in the Messenger and to deliver goods in the Packet. The trailer is a 56-inch tread two-wheel cart on ball bearing wire wheels with pneumatic tires arranged to attach to the springs of a Ford or other light car, instead of the axle. The capacity is 400 pounds and the price $75.

Until its air-cooled engine is perfect the company will make a chassis with a four-cycle, four-cylinder, water-cooled engine, with magneto ignition, friction transmission with belt drive to rear wheel. The wheels are wire, the tread 40 inches and wheel base 90 inches. The engine will develop 16 to 22-horsepower. The gasoline capacity is four gallons. The front springs are full elliptic and the rear semi-elliptic. The delivery car has a panel body 28 1-2 by 51 1-2 inches by 4 feet high and will carry thirty-six single grocery delivery boxes. The capacity is 400 pounds and the price $400. The weight is 900 pounds. The same chassis is used for the pleasure car which has a sociable seat. The cars are electric lighted.

The Twin City truck chassis will be continued at two-ton capacity at $1,350, with body to suit purchaser.

A Record 10 Months for National Company

INDIANAPOLIS, IND., July 25—The annual meeting of the stockholders of the National Motor Vehicle Co. was held this week. According to George M. Dickson, general manager, the season just closed has been an exceptionally good one.

"It has been customary to hold these annual meetings in

Light car made by the Herreshoff Motor Sales Co., Troy, N. Y.

September," said Dickson, "but we closed our fiscal year this season on June 30, which gave us only a 10 months' year. As soon as inventory could be completed our reports were ready and show that the last 10 months have been the most successful the National car has ever enjoyed."

Dickson has been associated with the National company in executive positions for many years. In fact, many of the heads of departments at the National have been there for years, a striking contrast to the changing personnel of other automobile concerns. The National factory is operating full time, and Dickson said that business is maintaining a good average.

When questioned about the properties adjoining the National factory, which have been acquired by that company, Mr. Dickson stated that they were not ready to announce the details of the new National buildings, but this year's successful business meant that there would be no curtailment and that the addition contemplated would go forward as planned.

Illinois Garage Owners for Uniform Prices

DECATUR, ILL., July 28—One hundred garage owners from various points of Illinois assembled this week in Decatur to attend the convention of the Garage Owners' Assn. of Illinois, which was organized last winter in Chicago. William McGinley, president of the Decatur Automobile Club, delivered the address of welcome. He devoted considerable of his talk to the subject of good roads and tendered the association the co-operation of the Decatur club in any legislation that would work for the betterment of road conditions. Mr. McGinley was elected an honorary member of the association. Robert Bland of Chicago, president of the association, delivered one of the principal addresses of the convention. He referred to the drunken driver, the speed maniac and the man with so much money that he did not care how many fines he was assessed, as the three classes of the motorist who are a menace to the automobile industry as well as to society. It is these whom the garage owners association are fighting and they are to be found in all walks of life.

C. B. O'Hara of Chicago, discussed the various qualities of gasoline on the market and furnished some interesting observations on prices and variations in grades.

Sparta reported that the city and county had been completely organized, every garage owner being in line and that the result had been an agreement to establish uniform prices for gasoline and accessories, the combination ensuring better service for the public.

Chalmers Absorbs Boston Distributor

BOSTON, MASS., July 25—On August 1 the Chalmers Motor Car Co. will take over the entire business of the Whitten-Gilmore Co., that has handled the Chalmers cars in Boston and vicinity for several years. The Whitten-Gilmore Co. will go out of business entirely and the partnership of Ernest A. Gilmore and Charles E. Whitten will be dissolved. Mr. Whitten has the agency for a line of cars and trucks at Lynn, Mass., that he will continue. Mr. Gilmore will take a vacation for some weeks before he does anything. Already a number of makers are trying to get him to take over an agency for their cars. The dissolution of the partnership will throw the agencies for the Saxon car and the Federal trucks on the market.

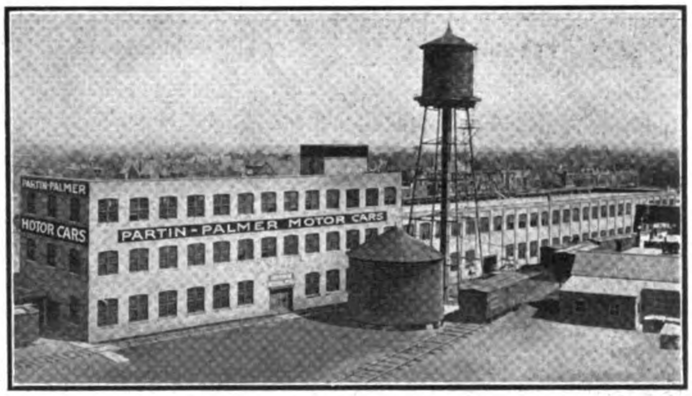
Eastern Jeffery Distribition for Poertner Co.

NEW YORK CITY, July 27—The Poertner Motor Car Co. has been appointed eastern distributer for the Jeffery car, manufactured by the Thomas B. Jeffery Co., Kenosha, Wis. The Poertner company will continue to handle the National and Waverly cars. The salesrooms now located at 1922 Broadway will be removed to 1759 Broadway.

New York Taxicab Competition in Sight

NEW YORK CITY, July 28—The International Cab Co. will on October 1 begin operating taxicabs in this city with charges of $.25 for the first half mile and $.05 for each additional quarter mile, making $.35 for the first mile, and $.25 for additional miles. P. J. Holdsworth, formerly manager of the Yellow Taxicab Co., will be general manager of the new service.

Upon the heels of this announcement is the statement that the Mason-Seaman Transportation Co. will put 200 taxicabs into service at about half the present rates. This would make the tariff $.20 for the first half mile and $.05 each for additional quarter miles. These 200 cabs will be for public hacking only and will not respond to telephone orders. If the experiment is successful more cars will be employed.



New plant of Partin Mfg. Co., Chicago, Ill.

Partin Co. Takes Over Staver Plant

CHICAGO, ILL., July 28—The Partin Mfg. Co., this city, has acquired the large automobile plant formerly operated by the Staver Automobile Co. at Auburn Park Station, Chicago.

Chassis and Body Parts Given Drawback

WASHINGTON, D. C., July 23—A drawback allowance was today granted by the treasury department on the exportation of automobiles and automobile bodies manufactured by J. M. Quinby & Co., Newark, N. J., with the use of imported chassis, aluminum, hardware, metal fittings, plate glass, woolen carriage cloth, various kinds of laces, carpet, waterproofed fabrics for tops, leather, metal chains, rubber tires and other fabrics and materials.

Briggs-Detroiter Dealers in Session

DETROIT, MICH., July 25—Beginning Monday, July 27, the annual convention of dealers handling the Briggs-Detroiter will take place under a big tent specially set up for that purpose on the factory grounds of the Briggs-Detroiter Co. "We expect such a large gathering that we could not take care of them in our offices," said one of the officials of the company. "Anyhow, with this warm weather the men will rather like the idea of being outdoors."

Grossman Pays 100 Cents on the Dollar

NEW YORK CITY, July 27—The creditors' committee, which took charge of the Emil Grossman Mfg. Co., last January, has turned the business back to Emil Grossman unconditionally. At that time it was promised to pay 100 cents on the dollar and this obligation has been fulfilled.

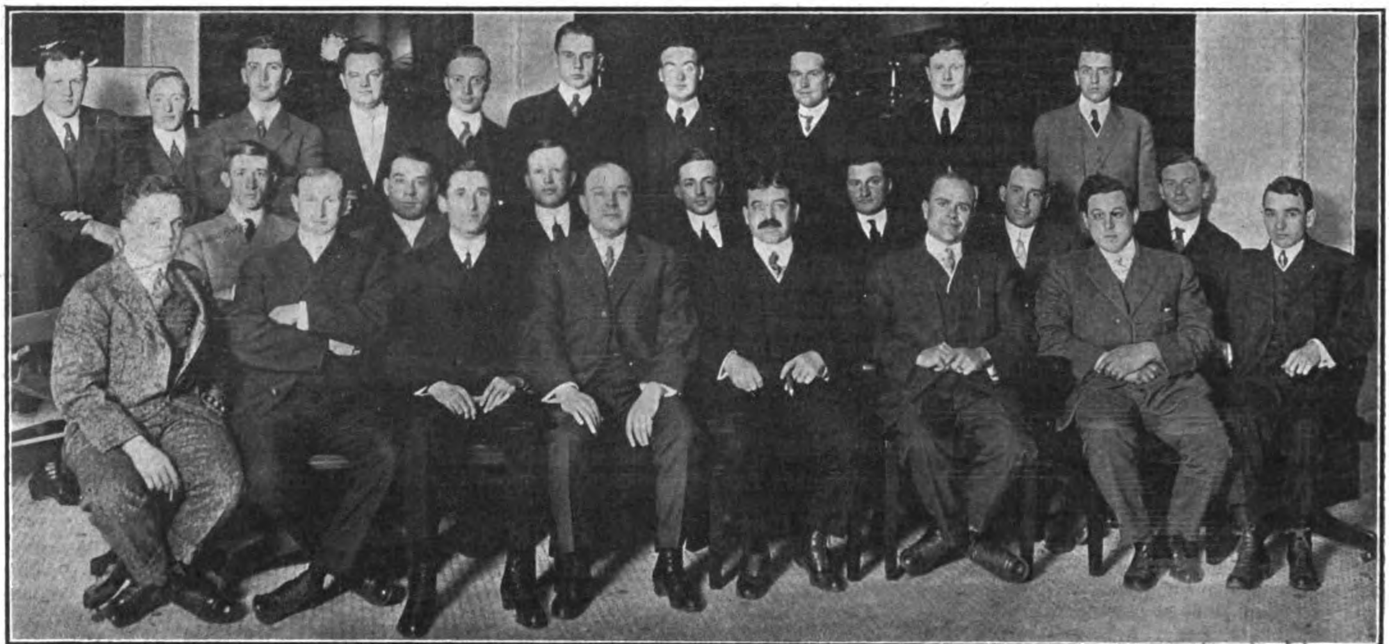
The creditors' committee was appointed for the protection of creditors and customers on Jan. 20, and was due to the facts that the removal of the Grossman factories from New York and Detroit, the installation of additional machinery and equipment, the erection of three new buildings and two kilns at Trenton, N. J., proved a tremendous drain on the cash resources as a result of not producing goods for 2 months.

Notwithstanding the disadvantages under which the Grossman company has been operating it is stated that substantial increases in both business and profits have been made and it is stated that 348 manufacturers have contracted for Red Head spark plugs alone.

Hayden Is Pullman General Manager

YORK, PA., July 24—At a recent meeting of the stockholders of the Pullman Motor Car Co., this city, the following changes were made: H. W. Hayden, general manager; H. W. Conrad, sales manager; J. J. Croghan, auditor, and C. G. Swartz, superintendent.

DETROIT, MICH., July 29—*Special Telegram*—The K. C. B. Co., with a capital of $200,000, has been organized here to bring out a new carbureter for heavy fuel. This company is a reorganization of the Chambray Carbureter Co. The incorporators are: J. H. Chambers, C. H. Bennett and A. A. Leslie, all officers of the Chambray company.



Recent meeting of San Francisco sales force of the Pacific KisselKar branch

A Test of Safety Signals by Life Protective Society

Danger of Rear-End Collisions Obviated by Devices Shown to N. Y. Safety First Society

NEW YORK CITY, July 25—A demonstration of a number of ways in which the driver of a car can make known to those behind him whether he intends turning right or left or stopping was held yesterday under the auspices of the Automobile Technical Sub-Committee on Street Traffic of the Safety First Society, New York. While most of the devices were thoroughly practical and worked well, only one or two have reached the stage where they are offered for sale.

The demonstration was held at 119th Street and Claremont Avenue and was divided into two parts. At 5 o'clock p. m. the daylight test was made and at 8:30 the dark test, in which the illuminating features were brought out. The cars carrying the signals were sent, one at a time, around the block, paced by a motorcycle and followed by the committee car. In all cases the signals did what was required of them. The Automobile Technical Sub-Committee consists of A. B. Cumner, Chairman; David Beecroft, Arthur J. Slade, George H. Robertson, Joseph Tracy and Frederick H. Elliott, Secretary.

The following brief descriptions of the devices shown will serve to give an idea of the many tentative solutions of the problem of eliminating the danger of accidents from rear-end collisions:

Walz Has Three Openings

The Walz Auto Direction Signal, shown by E. A. Walz, Jr., 505 Fifth avenue, consists of a metal casing attached to the rear of the car, having three glazed openings behind which are electric lights. Two of the openings are at right and left of the device, near the top, and are quite large, while the third, below them and in the middle is smaller, is fitted with a red lens and is the regulation tail-light. The larger openings are illuminated by the manipulation of a switch under the driver's control. When the one on the right is lighted up it shows an arrow-head pointing to the right, indicating that the car is about to turn to the right; on the other side the arrow of course points to the left. Illuminating both arrows at the same time indicates "stop."

The device exhibited by James M. Pugh, 1978 Bathgate avenue, Bronx, is of the shutter type, there being a horizontal row of metal slats that can be turned with either of their flat sides outward or edgewise. The flat sides are lettered "Left" and "Right" and the device is operated by magnets controlled by a switch under the driver's hand. An electric light illuminates the letters at night, and a red tail light is part of the device.

What looked like a diminutive railroad signal attached to the right rear fender was the signal devised by Lester D. Mayne, 110 W. 40th street, New York. An arm carrying three lenses in a row is pivoted to swing across the face of an electric light carried on a standard. The side lenses are lettered "L" for left, "R" for right and the middle one "S" for stop and the control, which is through a steel cable operated by a sort of selective lever working in a notched plate, causes the desired lens to be brought in front of the lamp. The lever is worked by pressure of the driver's arm, so that he does not have to take his hand from the steering wheel.

Signatelle—A Semaphore Type

The Signatelle was shown by Dr. Joseph Mandelbaum, 332 W. 145th street, New York, and is of the semaphore type in that when the driver is about to turn to right or left the signal throws up an arrow-shaped arm pointing in the proper direction and at the same time rings an electric bell. When the car is to stop a slide goes up revealing the word "Stop" in illuminated letters on a glass plate. At night the arrows each carry two small electric bulbs.

Auto Signalite Uses Cylinder

The Auto Signalite is of less recent vintage than most of the signals shown, being already on the market. It has a horizontal cylindrical casing with an opening through which the words "Right," "Left" and "Stop" appear when the roller device carrying the lettering is brought around by the driver. The device is made by the Auto Signalite Co., 737 Seventh avenue, New York.

The Grinden Art Metal Co., 427 Marcy avenue, Brooklyn, showed a signal with three glass panels, one on the right, one on the left and the third below the other two, with the necessary lettering for right, left and stop, the latter at the bottom. Lamps inside the casing illuminate the letters.

Gibson Has Two Lenses

William Gibson, 440 E. 156th street, New York, showed a lamp with two lenses one above the other and illuminated by the same lamp. The lower lens, which is green, is covered by a brass shield ordinarily, and the upper lens, which is red, left exposed as a tail light. When the car is to stop the green lens is uncovered automatically, being connected with the brakes so that a red light above a green one shows, railroad style.

The Au-To-C illuminator shown by Harry Searles, 1187 Halsey street, Brooklyn, is an illuminated license number, the figures being formed on glass and thrown into sharp relief by a lamp behind the glass.

Perhaps the most unusual signal in the lot was the Auto-Block, shown by Geo. A. Cole, of Hayes & Diefenderfer, 21 W. 62d street, New York. The signal is on the front of the car. There are two yellow disks, each about 4 inches in diameter, and each with an electric lamp in its center. The disks are on the ends of long spring steel strips which, when levers are moved, shoot out some eighteen inches or so and allow the lamp and disk to wave up and down in a rather startling manner. The signal can be seen from either front or rear because of its projection. Both disks out at once means stop.

Edward Stern, 40 W. 13th street, New York, showed the Nokolyd signal, which is of the illuminated type with lettered glass panels in front of an inclosed electric light. The signal was mounted on the right rear fender.

200 at Hupp Dealers Congress

DETROIT, MICH., July 25—The second annual Hupmobile convention will take place at the plant of the Hupp Motor Car Co., July 20 to August 1, with the presence of about 200 dealers who are expected from all over the country and abroad.

The programme is as follows:

July 30—Registration of dealers and informal reception of the dealers by President J. W. Drake. In the afternoon the dealers will be given a boat ride and supper at Bob-Lo.

July 31—Morning session: Talk on "The Medium-Priced Car Dealer Has a Staple Product," by F. J. Money, sales and advertising manager; "International Selling Methods," by C. H. Dunlap, general export manager; "Territorial Organizations," by A. C. Robbins, Los Angeles distributor; "Spirit of Service," by F. G. Fox; "Direct by Mail Advertising," by Palmer E. Winslow, advertising department; "Newspaper Advertising," by M. G. Ward, of the Dunlap-Ward Advertising Company; "Hupmobile Advertising Plans for 1915," by J. G. Roe, Hupp Motor Car Co., advertising department. Afternoon session: "The New Hupmobile Construction," by F. E. Watts, chief engineer; "Chassis and Electric Construction," by Don T. Hastings, assistant chief engineer. A detailed description will be given of the new car, and disassembled and assembled parts, etc., shown during the course of this lecture. Evening: Theater party at the Temple.

August 1—"Hupmobile Plant Organization and Factory Capacity," by S. H. Humphrey, manufacturing manager. Trip through the plant under Mr. Humphrey's direction. Further discussion on new models and display of new cars in factory sales rooms. Evening: Banquet at Hotel Pontchartrain.

Packard Uses Tungsten Valves

DETROIT, MICH., July 24.—In the July 16 issue of THE AUTOMOBILE it was stated that the valves in the Packard motors are nickel steel. This is an error, as the Packard valves are tungsten steel.

Coupe de l'Auto Course Picked in Auvergne

PARIS, July 15—Piston displacement has been reduced from 183 to 153 cubic inches for this year's *Coupe de l'Auto* race, and in order to make the event unusually difficult a mountainous course has been selected through Auvergne, where brakes will be an important factor. At present only nine entries have been received. These comprise three Mors cars, two Scap, one Pierron, and three Peugeots. These latter will be driven by Boillot, Goux and Rigal. It is announced that one of the Mors racers will be handled by Demogeot.

On the same day, and over the same course, it is intended to run a race for light cars having motors with a piston displacement of 85 cubic inches maximum.

Lindhe Sold Shim Patent Rights?

NEW YORK CITY, July 27—In the case of Eric G. Lindhe against the Laminated Shim Co., a bill of particulars has been filed by the defendant in answer to the motion for same, made July 3 by the plaintiff.

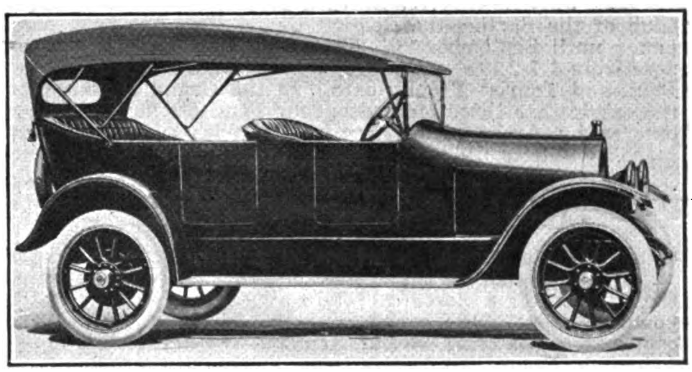
In this bill of particulars the defendant alleges that the contract, pursuant to which patent No. 969,709, covering the shim involved in the suit, was obtained and assigned to the Lindhe Shim Co., was a verbal one between William B. Nisbet, Theodore B. Nisbet and Carlton N. Aborn, who supplied the Lindhe Shim Co. finances, and Eric G. Lindhe, about August, 1910. The defendant further alleges that the said contract was employed to construct a special machine for the making of shims under the patent mentioned. This machine was made, according to the defendant, in April, 1911, before the application of Lindhe for the patent. The "authorization, full knowledge and consent" of the plaintiff to the sale of the patent rights of the Lindhe Shim Co. to Frederick P. Craig is said to be in writing and forms a part of the minutes of the Lindhe Shim Co. It is also alleged that the transfer from Frederick P. Craig to the Laminated Shim Co., Inc., of these rights is in writing and a matter of public record.

Convention of Jeffery Dealers Called

KENOSHA, WIS., July 27—Five hundred dealers representing all sections of the country will be in attendance at the Jeffery Chesterfield convention, to be held at Kenosha, August 4 and 5, at the factory of the Thomas B. Jeffery Co. The announcement of the Jeffery Chesterfield six, illustrated herewith, and which was described in THE AUTOMOBILE for July 23, will undoubtedly result in many changes in Jeffery representation in many sections of the country with new additions to the organization. Two days will be given to the assignment of territory to visiting dealers, the exhibition of the new cars and demonstration of the Jeffery Quad, the truck of Jeffery manufacture which has been adopted by the United States Government.

Chesterfield has 34 by 4 Inch Tires

In the description of the new Chesterfield Jeffery six which appeared in THE AUTOMOBILE for July 23 it was stated that 33 by 4-inch tires are used. This was a typographical error, as 34 by 4 tires are the correct size.



The new Jeffery Chesterfield six selling for $1,650, which is to be introduced to the dealers at the convention to be held at the factory August 4 and 5. The car uses 34 by 4-inch tires

Group of the district representatives of the Thomas B. Jeffery Company, Kenosha, Wis., who were in conference at the factory last week. These men will have charge of Jeffery distribution in the twenty-three districts into which the country has been divided

Dodge Bros. to Employ 10,000 in October

DETROIT, MICH., July 28—*Special Telegram*—Dodge Bros. will put about 10,000 men to work beginning October when a million dollar addition to the plant will be completed. This consists of a four-story assembly room, 1,000 feet long and 70 feet wide, and a press punching building. Machinery worth $300,000 will be installed. The total floor space will be 20 acres and will make it one of the largest factories in the country. A testing track in the shape of a racing circle of a quarter of a mile is being planned.

Col. Pope Can Sell Personal Property of Co.

HARTFORD, CONN., July 28—By agreement of the parties, Judge Marcus H. Holcomb of the superior court passed a substitute order today concerning the sale of a part of the Pope Mfg. Co. assets in Connecticut. The substitute order authorizes Colonel George Pope, the receiver in the Connecticut jurisdiction to sell at his discretion the personal property, not including cash or receivables, at prices not less than 70 per cent. of the inventory value in the smaller sales and no sale over $5,000 shall be less than inventory value without the approval of the superior court or a judge of that court.

The appeal of the Boston creditors' committee from the original order of Judge Holcomb allowing Receiver Pope to sell the property at his discretion as to prices, was withdrawn today and it is understood that about $40,000 worth of the machinery and material can be disposed of immediately. The court order allowing Receiver Pope to conduct the manufacturing business expires August 20 and the factory will close at that time.

Belgian Grand Prix for September 20

PARIS, July 21—By reason of a protest by the Automobile Club of the Sarthe, the Belgian Grand Prix has been postponed until September 20. There will be two races for, respectively 4 1-2 liter machines as built for the French Grand Prix, and Tourist Trophy cars. In the Grand Prix section the entries are three Mercedes, four Peugeots, and a Delage entered by Arthur Duray. The Mercedes entry has been made by Pilette, Belgian agent for this firm.

In the Tourist Trophy section the entries are three Minerva, an Abadal, a Gregoire, and three Sunbeams. The Sunbeam entry appears to have been made by the Belgian agent for this firm, and it is very doubtful if the factory will confirm it.

Market Reports for the Week

There was a general reduction in prices this week in the markets. In the metal markets, tin and copper reduced their prices. Tin closed at $30.75 at a loss of $0.95 per 100 pounds. Electrolytic copper dropped $0.00 2-5 while Lake copper dropped $0.00 3-8 per pound. A further decline is anticipated. Sales thus far are light, as the future of the market depends upon developments in Europe. Lead was dull and unchanged. Pennsylvania petroleum dropped to $1.65 a barrel, a reduction of $0.05. Linseed oil rose $0.04, closing at $0.60, with a strong market. Up-river Para dropped $0.01, closing at $0.72.

Klaxon Brings Suit Against Newark Dealer

NEWARK, N. J., July 28—The Lovell-McConnell Mfg. Co., this city, maker of the Klaxon horn, has filed suit in the U. S. District Court in this city against the W. C. D. Motor Car Co., Lozier dealer; it is charged that the dealer infringes the original Klaxon patents, Nos. 923,048, 923,049 and 923,122, by using the Sparton horn as standard equipment. This is a different court district from those in which other Klaxon suits have been filed.

Studebaker Liabilities Shrink $2,216,000

NEW YORK CITY, July 29—Net earnings of the Studebaker Corp., for the 6 months ended June 31, after fixed charges, depreciation, etc., and before dividends, amounted to $3,027,844. The net earnings, on the same basis for the full year 1913, before dividends, amounted to $1,904,413.

The liabilities during the period have been reduced by $2,216,000. The cash on hand amounts to $3,228,000.

The net earnings after charges and depreciation of $3,027,844 reported by the Studebaker Corp. for the 6 months ended June 30, 1914 is equal to 9.2 per cent. on the common stock after deducting preferred dividends or at the rate of 18.4 per cent. for the year. This compares with 3.59 per cent. earned on the common stock for the year ended December 31, 1913.

Locomobile Co. Makes Statement of Condition

NEW YORK CITY, July 27—The Locomobile Co. of America, a corporation organized under the laws of West Virginia, reports the following statement of its condition on May 31, 1914:

Total	$12,299,673	$11,646,291

*Includes cash and debts receivable.

Iowa Spends $20,000,000 on Automobiles

DES MOINES, IA., July 25—Iowa bankers would like to depress the automobile business in Iowa "psychologically" or otherwise, according to leading Des Moines financiers who claim that the automobile industry has taken $20,000,000 out of Iowa this year.

"Whatever this psychological business depression is," says this banker, "I am convinced that the automobile industry is not suffering from it. I am sure that the automobile industry either has no nerves or is not of a skittish temperament.

"The amount of loans which Des Moines banks have outstanding is double what it was at this time last year. The automobile business is largely responsible for this condition. Farmers are buying automobiles faster than they can pay for them. They borrow money from the country banks on the prospects of enormous crops promised for this fall. The country banks borrow in turn from Des Moines banks.

"More than $20,000,000 already has been spent in Iowa for automobiles this year. The number of cars registered at the State House showed an increase of 25,000 over last year for the first six months of the year. The continued demand for money from the country banks indicates that the increase will be as great or greater for the last six months of the year.

"Nearly all this money is absolutely lost to Iowa. Not only does the actual cost of the automobiles go east but also a large share of the cost of maintenance. This is a heavy drain on the resources of the state. It would be well if the automobile business could be depressed for a time."

But Iowa distributors continue to report that they have only one trouble and that is to get cars enough to meet the demands from their territories.

Fuel Competition Brings Further Reductions

NEW YORK CITY, July 28—The Standard Oil Co. of New York has made a further reduction of a cent a gallon in the price of gasoline, largely as a result of competition. Both the Texas Co. and the Standard Oil are now quoting $.13 a gallon to the garages, in this city, Brooklyn and Long Island. The Gulf Refining Co. is still quoting $.14 for gasoline in this territory.

The price of gasoline has been reduced in St. Louis by the Standard Oil Co. to $0.10 2-5 a gallon, half a cent lower than it has been selling since the last previous cut. The gasoline price in East St. Louis, is a fraction of a cent higher than in St. Louis.

In New Jersey the gasoline war has culminated in a bench warrant being issued for the Standard Oil Co. of New Jersey, upon complaint of the Crew-Levick Oil Co., one of the several companies which have been engaged in that controversy. The price has been forced down to $.09 1-2 wholesale, in certain towns. The complaint charges that the Standard company is unreasonably cutting prices in an effort to wipe out smaller competitors.

Considerable surprise is being expressed as to the cause of the low price at which gasoline is being sold by some dealers in Rochester. Prices have been cut there from $.17 to $.12 1-2, $.13 and $.14 a gallon. The recent decline in the price of crude oil at the wells has much to do with the downward trend of prices for petroleum products.

Prices around Boston and Hartford have remained about the same. In Boston, gasoline is sold at $.14 with no indication of change. In Hartford the same price prevails, a reduction having been made last week from $.15.

Goodrich Half Year Profits $2,651,278

NEW YORK CITY, July 28—The following statement is made by the B. F. Goodrich Co., relative to earnings for the first half of 1914:

"The books of the B. F. Goodrich Co. were closed on July 1 for the purpose of determining the results of operations for the first 6 months of 1914. They have not been audited by public accountants, but the company's auditor has just submitted to the directors a statement of earnings for the period.

"After making proper allowances for maintenance, depreciation, bad debts and all known outstanding liabilities, etc., the net profits for the period amounted to approximately $2,651,278. This amount added to the surplus carried over December 31, 1913, shows undivided profits of approximately $2,307,261, after deducting the regular April and July dividends on the preferred stock.

"From this amount the company has appropriated an amount sufficient to retire $900,000 par value of preferred stock. The amount of quick assets over current liabilities shows a gain of approximately $1,628,508 for the period."

Automobile Securities Quotations

NEW YORK CITY, July 29—War indications in Europe affected the stock market considerably this week, and accentuated the weak tone of practically all the listed securities. The unlisted stocks were also affected and although there were a few gains in both listed and unlisted securities there were a greater number of losses while about 1-3 of the automobile and allied securities remained at the same quotations as last week. The tire companies made the strongest showing, Firestone common having gained 10 points while the preferred gained 1-2 point. Kelly-Springfield common gained 2 points and the first preferred 3 points. Goodyear common advanced 6 points while the preferred declined 2 1-2. There was no change in most of the car companies although Reo Motor Car gained 1 point while Reo Motor Truck lost 1-2 and Studebaker common showed a gain of 1-2 point on the common and a loss of 1-2 point on the preferred. Oil stocks were generally weak, Texas Co. losing 15 points while Vacuum lost 9.

No Criminal Responsibility if Car Is Unmanageable

When a Part Becomes Deranged and Affects the Control, Driver Cannot Be Prosecuted for Accidents

WILMINGTON, DEL., July 27—Through the discharge from custody of Nathan H. Hutchins, who was arrested after a motor car he was driving had run down a child on the sidewalk, badly injuring her, the local authorities have made it plain that drivers of motor cars cannot be held criminally responsible for injuries sustained through accidents over which they have no control.

A car Hutchins was driving jumped onto the sidewalk last Friday, knocking down and running over Rosie Sammono, 9 years old, after which the police arrested him, charging reckless driving. It was found that the accident was due to a part on the machine becoming disarranged, causing it to become unmanageable, and when Hutchins was arraigned in the City Court on Saturday, Prosecuting Attorney John F. Lynn entered a nolle prosequi. The child is expected to recover. She is in the Delaware Hospital.

Form Club for New York Motor Tradesmen

NEW YORK CITY, July 27—For the purpose of providing a social organization for the motor tradesmen of New York City, the Motor Club, Inc., has been formed and has taken possession of the rooms at 222 West 59th street, formerly occupied by the now defunct Manhattan Automobile Club. A restaurant, bar, billiard rooms, library and other essential club adjuncts are provided and members are admitted upon payment of an annual fee of $20.

Aside from its social features the organization plans to use its influence in legislative matters. Dances, entertainments and club runs are planned.

F. S. Toback was elected president of the club at a meeting held on July 28. The other officers are: P. J. McShane, vice-president; W. C. Poertner, second vice-president; J. P. Nichols, treasurer and E. F. Korbel, secretary.

U. S. L. Receivers File $100,000 Bond

BUFFALO, N. Y., July 29—J. O. Moore and J. A. Roberts, receivers of the United States Light & Heating Co., have filed a joint bond of $100,000. Judge Hazel appointed Moore and Roberts to the receivership on July 23. On that day, Louis S. Posner, council for the company. filed an answer to the action of the Central Trust Co. of New York, with a $220,000 claim, admitting all the allegations it contained and consenting to the receivership. The company is capitalized at $17,000,000.

The equity action of the trust company will be tried at a later date here in the Federal court.

Judge Hazel ordered the answer of A. H. Ackerman, vice-president of the U. S. Light & Heating Co., in which he admitted fraud and mismanagement on the part of the board of directors of the company and consented to the appointment of a receivership, be stricken out.

Bosch Demonstrates Its New Lighting System

NEW YORK CITY, July 23—A practical demonstration of its new lighting system was conducted by the Bosch Co. last night in the presence of representatives of the technical press. A Marmon car, which make is the first to be equipped with complete Bosch electrification was run over roads in the neighborhood of Fort Lee, under a variety of conditions. One purpose of the demonstration was to show the advantages which the company claims for its new design of head lamp. This lamp differs from the ordinary type in that instead of producing a long pencil ray the light is distributed more evenly about the entire width of the road in front of the car. This effect is obtained partly by the reflector, which is not strictly parabolic, but chiefly by the use of a special lamp, the filament of which is not concentrated in a focal point as is commonly the case but is spread over a comparatively large flat area.

The lamp is interesting from another point. A new standard lamp base has been adopted by the Bosch Co. as in its opinion the old bayonet type is inadequate. Two sizes have been standardized and all lamps and plug connections conform to one or the other. The new socket is also a bayonet design but by the use of flat surfaces instead of pins for holding the base in the socket a much steadier arrangement results.

To show the ample generating power of the dynamo and the adequacy of the Bosch carbon-pile method of regulation the car was run through a large range of speeds with the battery cut out. Above a certain easy running speed the light from the lamps was remarkably steady.

The installation on the Marmon includes the Bosch-Rushmore starting motor which showed itself well able to handle the six-cylinder motor.

FREMONT, OHIO, July 27—At the annual meeting of the stockholders of the Lauth-Juergens Motor Car Co., Fremont, O., the following were elected directors: J. W. Worst, A. E. Culbert, H. H. Weinhart, J. W. Forsythe, W. A. Lucas, Theodore Juergens and L. C. Worst.

Offers $6,500 for Cameron Co. Assets

HARTFORD, CONN., July 28—E. S. Cameron in the bankruptcy court in New Haven has just made an offer of $6,500 for the assets of the Cameron Automobile Co., of West Haven, which recently went into bankruptcy. The purpose of the hearing before Referee Carleton E. Hoadley was also to decide whether or not the referee could re-open the case and authorize J. Birney Tuttle, an attorney who was appointed trustee, to accept an offer of $17,500 for the assets which was made later. Counsel for the interested parties argued the case which was continued until August 4.

Efficiency Survey Discusses Car Units

CHICAGO, ILL., July 23—At a meeting of the board of technical detail of the American Efficiency Survey of Motor Car Units, held at the Chicago Automobile Club last night, eight units were passed upon and many of the present units in test discussed. The meeting was the result of the efforts of President Harry Newman, who, knowing that the members would be in Chicago, arranged a dinner at the Automobile Club, and there discussed and passed upon various units. Of the seventy-three units to be tested the following ten have already been completed: Spark plugs, magnetos, tires, oil, ignition cable, jacks, hand pumps, power pumps, tow line and brake lining.

The American Efficiency Survey of Motor Car Units, using the testing laboratories of Purdue University, is an organization founded for the purpose of testing all the parts which go to make up a motor car and publishing the reports of these tests in the form of a bulletin. The tests continue through day and night for perhaps many months and engineers in the laboratory are said to take readings every 30 seconds throughout the entire testing period. In other words, after a test by the survey, it is expected that the device will have shown all its characteristics and a report can be given out telling its value with relation to similar devices and just how it acted under varied conditions. A report on the units just passed upon will be issued in 2 or 3 weeks, it is stated. At present tests of motors, carbureters and speedometers are being conducted.

The board which considers the passing or rejection of units is composed of the following Purdue men: C. H. Benjamin, dean of the engineering schools; Prof. Louis E. Endsley, G. A. Young, M. J. Golden, C. F. Harding and R. G. Pilkington, resident engineer.

R-C-H and Hupp-Yeats Assets Bring $100,000

DETROIT, MICH., July 25—At the bankruptcy sale of real estate, machinery, equipment, pattern drawings, repair parts of the R-C-H Corporation and of the Hupp-Yeats Electric Car Co., Detroit, a total of about $100,000 was realized.

Walpole Creditors to Receive 4 Per Cent. Dividend

BOSTON, MASS., July 28—Judge Dodge, in the U. S. District Court, ordered another dividend of 4 per cent. to be paid to the creditors of the Walpole Tire & Rubber Co. $50,000 has been set aside for this purpose. This makes $171,000 thus far paid out.

ALPENA, MICH., July 27—The Besser Mfg. Co., a foundry, bid $5,200 for the plant of the bankrupt Alpena Motor Car Co., and it is probable that the sale will be confirmed by the referee in bankruptcy and the other parties interested. All told, the sale amounted to $6,200.

Speed without Negligence Not an Element of Manslaughter

Driver Who Failed to Slow Down to State Limit Not Held for Michigan Killing

LANSING, MICH., July 25—The supreme court of the state of Michigan, in a decision rendered today, held that the accidental killing of a person by an automobile, even when the car is exceeding the state speed limit, is not manslaughter unless culpable negligence has been proven.

The case concerns Wm. J. Barnes of Lansing, who accidentally ran down a girl in May, 1911, the victim dying in consequence of the accident. Barnes was convicted by the Ingham County Circuit Court, Judge Wiest of that court holding that inasmuch as the state law requires automobilists to slow down to ten miles an hour when approaching pedestrians that Barnes had failed to slow down his car, thus causing the accident. It was shown in the testimony that the girl in her excitement jumped in front of the car.

The supreme court held that Barnes could not be held guilty of manslaughter unless culpable negligence was shown.

Injunction in Twitchell Gauge Case

NEW YORK CITY, July 27—In the case of A. Schrader's Son, Inc., against the 35 Per Cent. Automobile Supply Co., alleging infringement of the Twitchell tire gauge, the plaintiff brought a motion for preliminary injunction on July 20 and July 22 the order for a preliminary injunction was issued *pendente lite*. The motion was not contested by the defendant, whose counsel, Lucius E. Varney, states that the company is not infringing the complainant's rights.

Four Missouri Counties Have No Cars

ST. LOUIS, MO., July 3—For the first 6 months of this year 46,143 automobiles were registered with the secretary of state according to figures made public by the official today. Of this number 10,680 are in the city of St. Louis which has 4,883 more cars registered than has Kansas City, whose citizens have placed 5,797 cars on the books. Jasper county led the counties with 1,465 and was followed by Buchannan with 1,331 while St. Louis county—St. Louis city not included—was third with 1,306. Four counties—Carter, Douglas, Ozark and Reynolds—have no registrations while Shannon and Taney counties have but two each.

During the six months licenses were issued to 5,207 chauffeurs and 849 dealers secured permits to do business in Missouri. The motorcycle registry showed 2,920 power bikes.

The money collected from the registration and applied to the good roads fund was $201,866.50.

Two septuagenarians were among the drivers licensed, one being seventy-one years old and the other a year older.

Minnesota Registrations, 56,634

MINNEAPOLIS, MINN., The state automobile directory issued July 1 places the total registration of automobiles in the state at 53,599 cars. Since then the number has gone to 56,634. The book is issued by Roscoe B. Anderson, Security Bank Building, the head of the Automobile Trail Blazing Assn. The book has outline maps to show the routes in the Northwest that are already blazed, fifteen in all. Monthly sheets will be issued to keep the book up to date. The registration for each car is good for 3 years, so the book starts back in 1912 when the new law was passed.

New Jersey Licenses Exceed 1913 by 9,000

TRENTON, N. J., July 17—During the first 6 months of the present year the State Department of Motor Vehicles has collected $668,393, or $6,947 more than the total sum collected during the entire year of 1913.

Comparison between the first 6 months of last year and this year shows that last year there were 40,394 registrations issued, as against 49,567 this year. The increase in registrations is therefore 9,173.

The number of drivers' licenses taken out this year shows an increase of 10,627 over the corresponding period last year. The licenses taken out this year amount to 55,532, while last year, for the same period, they were 44,905. Fines collected up to June 30, 1913, amounted to $4,716, while in 1914 they totaled $9,004.

Motors of Steel Now Made in Berlin

(*Continued from page* 225)

Steel is the material used wherever possible. It is very thin in the cover and the waterjacket. Even the valve chamber covers are made of light steel pieces. The intake conduits are built into the cylinder block and the space gained by the thin material admits of giving them a very uniform sectional area throughout their length. The exhaust pipe is a curved steel tube with walls from 1.5 to 2 millimeters thick. The cylinders are of a special steel and machined inside and outside, while the valve guides are turned from castings and pressed into the respective steel sleeves forming parts of the block. A special process, not disclosed, is followed in producing the joints of cylinders with waterjackets, of the jackets with their upper covers and of the valve boxes with the intake pipes.

A special design feature is that the cooling-water when it enters the cylinders is first led under the exhaust valve chambers before it can rise. For this purpose the apertures are provided which may be seen in the plan view below the section of the induction pipe.

A steel bedplate with bolt holes connects the lower cylinder ends and serves for the securing of the block to the crankcase and to increase the stability of the whole.

With regard to the exterior appearance of these and other steel motors of this manufacture a remarkable smoothness in lines and joints is a striking feature. The block shows no seams but, with its flanges and the exhaust pipe, appears as machined all over.

The weight, as compared with the lightest cast cylinders, is about one-third, but it is considered a greater advantage that the thin walls admit of a very effective water-cooling which in turn admits of increased compression and a much enhanced thermic efficiency of the motor. Another advantage is that almost any requirement of the designer with regard to shapes, the dimensions of conduits and the thickness of walls can be executed with great accuracy in the pressed-steel parts, so that no compromises, possibly affecting the operation, need to be made.

The question of price depends largely on the quantity of production. For small orders it comes relatively high, but in the case of mass production it can be made equal to or even lower than that for ordinary motors. The manufacture is already on a practical basis through its connections with large German automobile builders who will employ the products.—From *Der Motorwagen*, July 10.

Reading Torsion Dynamometers

AN improved method for taking optical readings from torsion dynamometers is described and illustrated by Volkmar Vieweg in *Zeitschrift des Vereines Deutscher Ingenieure* for June 20. It depends upon the use of a system of lenses which revolve with the dynamometer, the axis of the system being parallel with the shaft of rotation, and in whose focal plane are arranged the scale and the index to be observed. The advantages consist in the simplicity of the arrangement and in the sharpness and strong illumination of the images. It was originated at the Physico-Technical Government Institution at Charlottenburg.

Big Economy-Reliability Run for Wisconsin

Four Trophies in 3-Day, 472 Mile Tour — Special Economy Rules — Dealers Bid for Pathfinding

MILWAUKEE, WIS., July 27—Final arrangements just completed for the fourth annual Wisconsin State Automobile Assn. tour indicate that the run will be the most important held in America this year and may surpass in importance the best Glidden ever run. The tour will be an economy-reliability run, conducted under grade 1 rules of the A. A. A., with supplementary rules governing the economy part of it. The dates definitely selected are September 2, 3 and 4, and the route is 472 miles long. The contestants will fight for four trophies, the well-known $1,000 Sentinel cup, which is a sweepstakes trophy; a trophy just offered by *The Milwaukee Free Press*, for best road score; the new cup hung up by the *Wisconsin Motorist* for the winner of the economy division of the test, and the Emil Schandein cup, for private owners, which has been competed for three times in connection with the annual W. S. A. A. tours.

It is expected that there will be a considerable entry list from Milwaukee and Wisconsin dealers for the three trophies, and at least four or five private owners for the Schandein mug. There has been no state tour since 1912, the 1913 tour having been abandoned because of the lack of stock car registrations with the A. A. A. contest board. The 1914 tour was abandoned also, but revived as a combination economy-reliability run upon the demand of dealers for a stimulant to trade, which the runs have always been in the past.

The route will be as follows:

Wednesday, September 2—Milwaukee to Sheboygan, Manitowoc, Kewaunee, Algoma and Green Bay, Wis., 164.8 miles.

Thursday, September 3—Green Bay to Oshkosh, Fond du Lac, Beaver Dam and Madison, Wis., 147.6 miles.

Friday, September 4—Madison to Janesville, Beloit, Burlington, Kenosha, Racine and Milwaukee, 159.9 miles.

The pathfinder will be sent out with M. C. Moore as trail blazer about August 5. Dealers are now bidding for the honor of furnishing the pathfinding car and have until August 1 to quote the best figure.

George A. West, Wisconsin representative on the A. A. A. contest board, and treasurer of the W. S. A. A., who has handled all previous Wisconsin tours, will again act as referee.

31 Cars in Colorado Prize Parade

DENVER, COL., July 24—An evening parade of beautifully decorated and illuminated motor cars was one of the most attractive features of the Grand Lodge Golden Jubilee Session and Reunion of Elks, held in Denver last week. Thirty-one cars from Colorado and one from Utah competed for the $700 cash prizes and the fifteen special prizes of automobile accessories, watches, etc.

Visitors from Los Angeles, New Orleans and other cities making much of motor events of this kind pronounced the decorative and illuminative effects among the most artistic they had ever seen. The parade was in charge of the Denver Motor Club.

Fourteen Entries for Elgin Races

CHICAGO, ILL., July 28—The fourteenth Elgin entry is a specially built car nominated by Frederick Robinson, a theatrical man who has engaged Mort. Roberts to drive it. The car is called the Pahys, a Greek word meaning quick.

Billy Chandler in the Braender Bulldog and F. H. Dearborn in a third Stutz are late declarations for the races of August 21-22. All the cars are in both days, which makes a total of twenty-six nominations for the 2 days.

As the list now stands, the field is made up as follows: E. J. Schroeder's Peugeot, driver not named; Stutz, Oldfield; Stutz, Anderson; Sunbeam, Grant; Sunbeam, Babcock; Marmon, Heinemann; Marmon, driver not named; Mercedes, De Palma; Peugeot, Burman; Braender Bulldog, Chandler; Duesenberg, Rickenbacher; Duesenberg, driver not named.

Babcock, however, will not be found at the wheel of the Sunbeam because of an accident Sunday night at the course. Following a trip around the circuit, Babcock stopped at his camp. Getting ready to start again, his arm was broken in two places by the back kick of his motor. Babcock is in a serious condition and there is some fear of amputation. So far no new driver has been named.

Cy Patschke, who was to have driven Erbstein's Marmon, has been withdrawn because Mrs. Patschke objects to his driving. Erbstein now is trying to get either Howard Wilcox or Ralph Mulford.

Ray Harroun was at the course Saturday and engaged the camp for the Maxwell team which has not been entered as yet but which is surely coming. Harroun states that Moross will enter five cars. In addition to the three Maxwells there will be d'Alene's Marmon and Brock's Wright, which formerly was known as the Ray.

Mercer, Metz and National Star at Springfield

SPRINGFIELD, MASS., July 25—Fully 10,000 persons witnessed the amateur automobile races held this afternoon at Imperial Park.

The National, Metz and Mercer cars were the winners in the twelve events held.

One of the most interesting races of the day was when the small Metz stock runabout, driven by Barrett, competed with a Mercer, driven by Brainard. The Metz was given a handicap of 100 yards, and the little car stuck to it and won the 2-mile race in 3:07 2-5.

The 3-mile race between the National, Mercer and Knox cars started with the Mercer leading, but the National being pushed hard passed it shortly, and holding the pace came in first. The Mercer lost on the curves.

The Mercer driven by Laviolette broke the track record for 1 mile, when it negotiated the distance in 1:24 1-4. The former record was 1:27. This car also won the 3-mile flying start race, beating out Brainard's Mercer. Its time was 4:13 4-5.

Tetzlaff Breaks Washington Mile Record

SEATTLE, WASH., July 18—Tetzlaff, driving a Benz car, broke the state of Washington record for 1 mile at the Meadows track near this city on July 18, his time being 54 1-2 seconds. Cooper in his Stutz succeeded in capturing three of the four principal races of the day, while Klein appropriated the most hotly contested race of the day with his King.

On the second day's racing Tetzlaff succeeded in breaking his record of the day previous when his Benz made the distance in 53 2-5 seconds.

A $500,000 Speedway for Minneapolis

MINNEAPOLIS, MINN., July 27—Capitalists have put underway a plan to build a two-mile brick motor speedway within a short distance of the city limits of Minneapolis to cost $500,000, and to be ready by the fall of 1915. J. D. Hogan and William D. Hogan, land men, and closely associated with other capital, are back of the plan, and Orin Kellogg is connected with the enterprise which will be put on a bond or stock selling basis. After studying four different sections of the surrounding country of the Twin Cities, the Hogans have obtained a half section of land in Anoka county, within reach of the street car lines, not far from railroad lines and on the boulevard system of Hennepin and Ramsey counties, thus bringing both Minneapolis and St. Paul in close touch by automobile roads as well as traction lines. Little excavation work is necessary as the land is level. Large grandstands will be erected.

Car-Nation Covers 3,500 Miles in 8 Days

PHILADELPHIA, PA., July 27—A practical demonstration of the economy and endurance of the small car was concluded yesterday in Atlantic City by the Atlantic States Sales Co., local distributor of the Car-Nation. The Car-Nation selected for the test made six trips daily between the company's headquarters in North Broad street, this city, to Atlantic City, N. J., from July 17 to 26, inclusive.

The total distance covered by the car is approximately 3,500 miles in the 8 days.

Sealed Hupmobile Finishes 6,200 Miles

DETROIT, MICH., July 22—After having previously covered about 4,500 miles with its hood, battery box and starting crank handle sealed, a Hupmobile driven by Fred Perkins arrived in this city from Baton Rouge, La., having made the journey of 1,700 miles in 84 hours 28 minutes at a total operating expense of $29.22, or $0.017 per mile.

Perkins, who came with his wife and little daughter, was the bearer of a letter from the mayor of his home city to Mayor Marx, of Detroit. The executive and a party of city officials found the seals as Mayor A. Grouchy, Jr., of the Louisiana city had appended them.

Mr. Perkins had the hood of his Hupmobile sealed last January as the result of a wager which he made with friends who claimed he could not travel 2,000 miles over the roads of his home state with the car thus sealed. Not only did Perkins win his wager, but he continued the demonstration, and now has covered over 6,000 miles.

SAN FRANCISCO, CAL., July 25—Twenty-five thousand automobiles, the largest number of cars ever brought together at one time in the United States, took part in the fifty-mile parade in San Francisco July 15, which was named Automobile Day.

Two Herff-Brooks Cars for 1915

INDIANAPOLIS, IND., July 28—The Herff-Brooks Corp. line for 1915 will consist of a 50-horsepower, six-cylinder car with a bore of 4 and a stroke of 4 1-2 inches, and a 40-horsepower, four-cylinder car with 4 1-2-inch bore and 5-inch stroke, the cylinders in both motors being of the L-head type cast singly. The six-cylinder, five-passenger touring car, equipped with the Aplco electric system, sells for $1,375 and the four-cylinder, five-passenger car with the same equipment sells for $1,100. The equipment includes, beside the lighting and starting system, a one-man top. Bosch magneto, Stromberg carbureter, disappearing type of steering wheel, which permits of easy access to car from the front, new type of radiator, ventilated engine hood, Turkish upholstery and auxiliary seats in the touring cars. The cars are left drive with center control and are manufactured in both two- and five-passenger types.

Boston To Philadelphia in an Electric

BOSTON, MASS., July 28—A Detroit roadster recently completed a run from this city to Philadelphia, averaging 25.4 miles per hour. The trip was made in an elapsed time of 33 hours and 50 minutes, although the actual running time between the city limits was but 12 hours and 57 minutes.

The trip was undertaken to demonstrate the adaptability of the ordinary electric automobile for touring purposes, when suitable battery and tire equipment are installed; also the feasibility of boosting lead batteries efficiently and expediently. The car was equipped with Goodrich Silvertown Cord tires and was driven by R. L. Heberling, Philadelphia sales manager of the Philadelphia Storage Battery Co. The motive power was furnished by a 44-cell Philadelphia thin plate diamond grid storage battery.

300-Meter Hillclimb Record Is Broken

BOULOGNE-SUR-MER, July 22—Camille Jenatzy's 4-year old record for the 300 meters hill climb was broken in the first day of the Boulogne meeting. With a car having a piston displacement of 1,342 cubic inches, the late Belgian champion climbed the 328-yard hill, having a gradient of 14 per cent., with a standing start, 15 4-5 seconds. One of the Grand Prix Peugeots, built under the 274.6 cubic inch rule, cut this record to 14 3-5 seconds. This is at the rate of a little more than 47 miles an hour. Hispano-Suiza took second and third place in the racing car section with respectively 16 3-5 and 19 4-5 seconds.

In the touring car class a 30 h.p. Panhard-Levassor, Knight motor, made the best performance with 17 seconds. The car carried four passengers. Second place in this division was secured by a Hispano-Suiza in 18 seconds, followed by an Aquila-Italiana in 19 seconds. In the touring car section for cars competing for the Crespelle Cup, which embodies a series of varied tests, a four-cylinder 85 by 130 mm. Darracq made the best performance in 22 2-5 seconds. It was followed home by a Gregoire in 25 seconds, with a Hupmobile third in 27 1-5 seconds.

Wisconsin Registrations Pass 45,000 Mark

MADISON, WIS., July 27—Wisconsin motor car registrations passed the 45,000 mark on June 26. There seems to be no question that the total registry for 1914 will exceed the 50,000 mark. At the close of business on June 26 the figures were: private owners registered, 45,016 and the dealers, 1,160.

The total registration for 1913 was 34,646, and the 1914 list therefore shows a gain of nearly 30 per cent. on June 26, or to be exact, 29.9 per cent. The total revenue from all registrations is in excess of a quarter of a million dollars. At $5 each, 45,016 private owners' licenses amount to $225,080; 1,160 dealers' licenses at $10 make $11,600, and 6,748 motorcycle licenses at $2 figure $13,496, for a total of $250,176.

Lincoln Way Route Not To Be Changed

DETROIT, MICH., July 29—*Special Telegram*—Henry B. Joy, president of the Lincoln Highway Assn. sent the following reply to President Wilson, who some time ago asked the association to have the Lincoln Highway include Washington and Baltimore on its route:

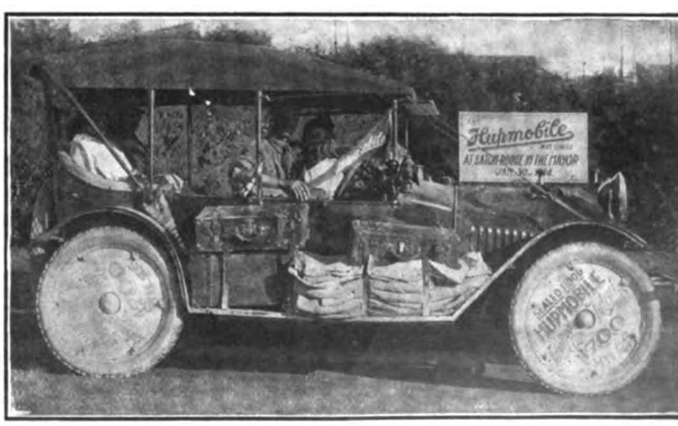
"Your letter addressed to me as president of the Lincoln Highway Association under date of June 19, was duly received and duly acknowledged. In that letter you suggested that the Lincoln Highway Association give its consent to the placing of the official Lincoln Highway markers along a route from Philadelphia to Baltimore, thence to Washington, thence to Frederick, thence to Gettysburg, thus re-routing the Lincoln highway via these cities and increasing the length of route by 17 miles between New York and San Francisco.

"I have delayed replying to your letter for many reasons, among them: First, of course, on account of the seriousness of the request as coming from you, the president, you who have so loyally supported the Lincoln memorial highway project and who sent to our association your check among the very first in support of this great and good enterprise. Second, to ascertain the attitude of the counties and cities lying between Philadelphia and Gettysburg and from which the Lincoln Highway would be diverted by the change in route you suggest. Third, to fully again review and reconsider the purpose and plan so carefuly originally adopted by our association after elaborate investigation and consideration. I am under the necessity of stating to you that the work of the Lincoln Highway Association, no doubt greatly assisted through your recognition of its work in its early stages, has progressed so favorably that there scarcely remains along the entire Lincoln way any section of its route which has not been marked and to a very great extent re-named. Especially is such the case between Philadelphia and Gettysburg, where in the counties traversed, and also in the cites of York, Lancaster, Coatesville, Columbia, Downingtown, etc., the official adoption by the local authorities of the name Lincoln way and the marking thereof and the betterments and beautification in process make the changing of the route in accordance with your suggestion, if for no other reasons, outside of and beyond the control of this association.

"The Lincoln Highway Association has committed and entrusted the Lincoln way to all the people and especially to the states, counties, villages and cities through which its route extends. It is not possible to undo the wonderful work of the communities whose loyal patriotic efforts are making, have indeed made the Lincoln Highway a part of the map of our country and whose plans for its improvement are being effectively carried forward according to the financial means and energies of these communities traversed, and the aid our association is able to extend the Lincoln way is the shortest, most direct and practicable route consistent with the topography of the country from New York on the Atlantic to San Francisco on the Pacific, and to change from that basic principle and extend its length by devious windings from city to city, or from point of interest to point of interest, would insure its failure as a permanent useful memorial way."

Booster Outing for September 17

NEW YORK CITY, July 29—The Village Boosters outing will be held on September 17 down on Fred Wagner's farm. The usual games will be participated in. There will also be a clambake.



Hupmobile, whose bonnet has been sealed since January

Factory Miscellany

MILWAUKEE'S Working Force Increases—Figures compiled by the retail merchants' division of the Merchants and Manufacturers' Assn., Milwaukee, Wis., show that there has been an increase of 5 per cent. in the number of workmen employed by Milwaukee metal-working shops of all kinds in 30 days. The general average of manufacturing plants is 80 per cent. of normal, while machine shops are operating 65 to 70 per cent. of normal. Retail sales show a large increase over the corresponding period of 1913, while cash sales are larger in volume and collections on credit sales are much improved.

Harrold Tool Adds—The H. J. Harrold Tool Co., Salem, O., manufacturer of all kinds of tools, automobile springs a specialty, will enlarge its plant and build an office.

Miller to Build Parts Plant—C. F. Miller, of Defiance, O., will erect a factory in Bryan, O., for the purpose of manufacturing automobile parts in addition to other products.

Will Reorganize Star Rubber—Stockholders of the Star Rubber Co., Akron, O., have decided to reorganize the company for the purpose of freeing the concern from a heavy indebtedness. A new organization will purchase and operate the plant.

Cole Service Bldg. in Plant—Since the completion of a new factory building the Cole Motor Car Co. has moved its service station and general offices from North Capitol avenue to its factory in East Washington street, Indianapolis. The company now has all of its offices and departments at the same place.

Packard and Ford Plants Closed—The plant of the Ford Motor Co., Detroit, is closed since July 22, and will not reopen until August 3, when the work of taking the annual inventory will be completed. The Packard Motor Car Co. will close its plant July 27 and remain closed during one week or less, for the same reason.

Oil Co. Buys Plant—The Winona Oil Co., Winona, Wis., has purchased the branch office, warehouse system, etc., of the Valvoline Oil Co. at Eau Claire, Wis., and will establish a tank wagon service covering Eau Claire, Chippewa Falls and surrounding territory. This is the fourth branch plant established by the Winona company.

Maxwell-Newcastle Plant Working—After a shut-down of 2 weeks, the plant of the Maxwell-Newcastle Mfg. Co., Newcastle, Ind., has resumed operations. About 1,000 men are now employed and the force is to be further increased. The company manufactures parts for cars formerly manufactured by the United Motors Co.

Miller Rubber Increases—The Miller Rubber Co., Akron, O., has planned to expand to a large degree, following the increasing of the capital stock from $1,000,000 to $2,000,000. The buildings, formerly occupied by the Franz Body Works, will be used to increase the capacity at once. Other large additions are contemplated.

Fisher Body Adds—A five-story building located at Forrest and Grandy avenues, Detroit, Mich., has been acquired by the Fisher Closed Body Co. and the Fisher Body Co., which are both under the same management. This will give the concerns about 100,000 square feet of additional floor space and enable them to employ about 600 more men.

Universal Adds More Men—The Universal Mfg. Co., Racine, Wis., which is making a compressed-air cranking device for motor cars, has been obliged to increase its shop facilities and add more men to take care of orders for the appliance. A special device is made for Ford cars and the demand from this source has swamped the concern.

Xenia Rubber Decides on Plant—At a meeting of the officers and stockholders of the Xenia Rubber Co., of Xenia, O., it was decided to locate the company's new plant in Xenia, and the purchase of a site on North Detroit street was authorized. Roy Bickett, manager of the company, states that the directors have decided to construct a two-story building, 50 by 100 feet, concrete and steel, sides constructed of steel and glass.

Dunkirk Plant Sold—L. A. Pease, referee in bankruptcy, July 18 confirmed the sale of the plant of the Motor and Mfg. Works Co., Dunkirk, N. Y., to E. K. Buttolph, of Dunkirk, for $3,500, subject to a judgment lien of $5,200. David Reid, former head of the company, following the sale to Buttolph declared he could secure a buyer at an advanced figure over the one bid by Mr. Buttolph, and Referee Pease postponed his report, but Reid failed to appear as he suggested July 16 at the creditors' meeting, and immediately the sale to Buttolph was confirmed. The company will be reorganized and the operation of the plant continued.

Parish & Bingham Adds—With the preparations for erecting a big power plant to adjoin the main building at Madison avenue and West One Hundred and Sixth street, the Parish & Bingham Co., Cleveland, O., maker of automobile frames, has under way an imposing construction unit. The main building, costing $140,000, and the office building, costing $25,000, will be ready for occupancy in two months. The main building is of the monitor type, 900 feet long. It is a model daylight factory and enclosed in glass. The present location of the Parish & Bingham Co. is on Hamilton avenue, near East Fifty-fifth street. The factory makes frames for Ford cars.

The Automobile Calendar

July-August	French Army Truck Subsidy Trials.
Aug. 1-3	Galveston, Tex., Beach Races.
Aug. 2-9	Grenoble, Automobile Club of France's 6-Day Motorcycle and Cyclecar Reliability Contest in French Alps.
Aug. 16	Le Mans, France, Automobile Club de la Sarthe's Coupé International Light-Car Race, 1 liter, 400 maximum cylinder area, 350-500 kilos weight.
Aug. 17	Le Mans, France, Auto Club de la Sarthe's Grand Prize de France for 4½ liter cars.
Aug. 21-22	Chicago, Ill., Elgin Road Races, Chicago Automobile Club.
Aug. 23	Auvergne, France, Coupé de l'Auto Race.
Aug. 27	Brooklands Track, England; Annual Automobile Race.
Aug.	Denver, Colo., 650-mile Run, Colorado Springs to Salt Lake City.
Aug.	Russia, Road Race, Coupe de l'Empereur, 2,500 miles.
Sept. 6-7	Brescia, Italy, Auto Club of Italy's 4½-liter Grand Prize.
Sept. 6-7-8	Newark, N. J., Cyclecar Reliability Tour to Atlantic City.
Sept. 7-14	Indianapolis, Ind., Automobile Show, Indianapolis Automobile Trade Assn.
Sept. 9	Corona, Cal., Road Race, Corona Auto Assn.
Sept. 10	Portsmouth, Eng., Autumn Conference, Institute of Metals.
Sept. 10-15	Berlin, Germany, German 4½-liter race.
Sept. 15-Oct. 11	New York City, Commercial Tercentenary Celebration.
Sept. 26	Brooklands Track, England, Annual Automobile Race.
Sept. 26-Oct. 6	Berlin, Germany, Automobile Show.
Oct.	Philadelphia, Pa., E. V. A. A. Annual Convention.
Oct. 4	St. Louis, Mo., Automobile Show, Auto Manufacturers' and Dealers' Assn.
Oct. 7-17	New York City Electric Vehicle Show, Grand Central Palace.
Oct. 9-Nov. 2	S. A. E. European Trip.
Oct. 16-26	Paris, France, Automobile Salon.
Oct. 17-24	Pittsburgh, Pa., Automobile Show, Auto Dealers Assn., Inc.
Oct. 19, 20, 21	Philadelphia, Pa., Elec. Veh. Assn.'s Convention.
Oct. 19-26	Atlanta, Ga., American Road Congress of the American Highway Assn. and the A. A. A.
Oct. 28-31	Milwaukee, Wis., Convention, Northwestern Road Congress, Auditorium.
Nov.	El Paso, Tex., Phoenix Road Race, El Paso Auto Club.
Nov. 6-14	London, England; Olympia Show.
Nov. 8-9	El Paso to Phoenix, Ariz., Automobile Race.
Nov. 8-11	Shreveport, La., Track Meet, Shreveport Auto Club.
Nov. 15	Paris, France, Kerosene Motor Competition.
Jan. 2-9	New York City, Annual Automobile Show, Grand Central Palace.
Jan. 23-30	Chicago, Ill., Automobile Show, First Regiment Armory.

The Week in  the Industry

Motor Men in New Roles

SILLS Chevrolet Sales Manager—W. C. Sills, who has been in charge of the Boston branch of the Chevrolet Motor Co., New York City, has been appointed general sales manager of that company, with headquarters in that city.

Fisher Off for Europe—Carl G. Fisher, president of the Indianapolis Speedway, sailed for Europe on the *Imperator* on July 25.

Reese Goodyear Manager—Woodson Reese has been appointed manager of the local branch of the Goodyear Tire & Rubber Co., Philadelphia, Pa.

Vogler Maxwell Sales Manager—H. J. Vogler has been made district sales manager for the Philadelphia (Pa.) territory of the Maxwell Motor Co., Detroit, Mich.

Connects With Wagenhals Co.—The former automobile editor of La Presse, a Montreal newspaper, W. Robinson, has become identified with the Wagenhals Motor Car Co., Detroit.

Barnes Joins Federal Truck—L. I. Barnes has joined the sales organization of the Federal Motor Truck Co., Detroit, Mich., and will have charge of the sales development movement in the South.

Hook with Mercer—R. C. Hook has just joined the sales force of the Mercer Automobile Co., Trenton, N. J. Prior to his Mercer connection Mr. Hook was associated with the Motor Shop of Trenton.

Atkinson Resigns—Robert Atkinson, who has been associated with many of the prominent automobile firms in the Northwest, and recently manager of the Hudson agency in Seattle, has severed his connection with that company.

Capt. Gray Resigns—Capt. W. H. Gray, who has been manager of the Northwest Auto Co. in Portland, Ore., for the past 2 years, has resigned. He will take several weeks vacation before entering the automobile business again.

Bloomfield Monarch Representative—The Monarch Motor Car Co., Detroit, Mich., has appointed William Bloomfield as a special representative for the states of Alabama, Louisiana and Mississippi, with headquarters in Birmingham, Ala.

Case Joins Paige-Detroit—Julian Case, formerly manager of the advertising departments of the Regal Motor Car Co., Detroit, Mich., and the Abbott Motor Car Co., is now with the advertising department of the Paige-Detroit Motor Car Co., Detroit.

Jordan Back in Boston—George N. Jordan has returned to Boston, Mass., again to take a position as assistant manager of the wholesale branch of the Studebaker Corp. under Henry Myers. He will travel through New England for the company.

Voorhis Joins Oakland—C. B. Voorhis has resigned his position as assistant general manager of the Kingman Plow Co., of Peoria, Ill., and becomes assistant sales manager of the Oakland Motor Co., Pontiac, Mich., under F. W. Warner, general sales manager.

Changes in Indianapolis—Will H. Brown and Sam Renick have taken over the interests of E. Beveridge Dill in the United Supply and Accessory Co., Indianapolis. Mr. Dill retires as president and general manager, but Grant Newby will retain his interest in the company.

Blossom Sails for Europe—C. W. Blossom, of The Grant-Lees Gear Co., Cleveland, O., sailed on the S. S. *Caronia* from Boston on Tuesday, July 14, to investigate European manufacture of silent chains. He will spend considerable time at the Coventry silent chain factory in Coventry.

Wood Heads Abbott's Detroit Branch—The Abbott Motor Car Co., Detroit, Mich., has opened a new branch in Detroit, at 467 Woodward avenue. L. E. Wood, sales manager of the company, has charge of the branch, while O. A. Schreiber, who has been with the concern for many years, is assistant to Mr. Wood.

Chandler Factory Representative Mondex Absorber—W. R. Chandler has been appointed factory representative of the A. & J. Mfg. Co., Binghamton, N. Y., which has just completed negotiations for the exclusive manufacturing of the new Mondex shock absorbers. He has opened offices in the U. S. Tire Bldg., New York City.

Holton Monarch Sales Manager—Hoover Holton, formerly general sales manager of the Empire Automobile Co., and of the American Motors Co., Indianapolis, Ind., has been appointed general sales manager of the Monarch Motor Car Co., Detroit, which is making a four-cylinder car listed at $1,000 and a six-cylinder car costing $1,400.

Kaufman Sailing for Europe—Carl Kaufman, general manager and treasurer of The Motor Car Equipment Co., New York City, accompanied by his wife and daughter, will sail for England the first week in August. Mr. Kaufman will look into the development of the motor accessory line abroad and attend the automobile shows in Berlin and Paris.

Moore Gets Boost—E. A. Moore, production manager of the Fairbanks-Morse Mfg. Co., Beloit, Wis., has been appointed general manager of the gas engine department to succeed F. E. Greene, who resigned recently. Mr. Moore is an internal combustion engineer and has been associated with the Fairbanks-Morse and other engine builders for many years.

Baker Heads Franklin Service Dept.—E. L. Baker has been appointed head of the service department of the H. H. Franklin Mfg. Co., Syracuse, N. Y., to succeed Ralph Murphy, who is now chief engineer. Mr. Baker has been connected with the Franklin engineering department several years and for the past year and a half has been resident engineer on the Pacific Coast.

Daniels May Build Light Car—It is reported in Detroit, Mich., that a new concern to manufacture a light car is now being formed by George E. Daniels, formerly vice-president and general manager of the Oakland Motor Car Co., Pontiac, Mich.; Howard Bauer, former assistant sales manager of this company, and J. H. Newmark, former advertising manager of the same concern.

Roberts Joins Oakland—R. K. Roberts, of San Francisco, Cal., has been named assistant general sales manager of the Oakland Motor Car Co., and will be given entire charge of the Oakland business on the Pacific Coast, embracing California, Oregon, Washington, Idaho, Nevada, Utah, British Columbia and the Hawaiian Islands. Mr. Roberts was formerly identified with the management of the Howard Automobile Co. in California.

Bowen Heads New S. G. V. Agency—The agency for S. G. V. cars for the Metropolitan district was transferred last week to the Whitefield Motor Car Co., New York City. This new concern will succeed the Gotham Motor Car Co. The Whitefield company will be located at 242 West Fifty-ninth street. F. H. Bowen is general manager. The directors of the new company are A. L. Corey, M. J. O'Brien, Jr., D. W. Wilworth, Seth B. French, H. W. Carhart and F. H. Bowen.

Garage and Dealers' Field

Michel Advertising Co. Moves—A. Eugene Michel, advertising agent, New York City, has changed his address in Chicago, Ill., from the Rookery to 225 East Twenty-second street.

Will Handle Timken Axle Parts—Jos. C. Gorey & Co., 354 West Fiftieth street, New York City, will handle a complete line of parts for Timken front and rear axles from 1907-1915 types on and after August 1, 1914.

Adopt Westinghouse System—The Westinghouse Electric & Mfg. Co., of East Pittsburgh, Pa., announces that the Singer Motor Co., Inc., Long Island City, N. Y., has adopted the Westinghouse electric starting and lighting system for its 1915 cars. This equipment consists of starting motor and lighting generator with the complete equipment of switches, fuse blocks and voltmeters. This company also announces the adoption by the American La France Fire Engine Co., Elmira, N. Y., of the Westinghouse electric automobile equipment for fire trucks manufactured by this company.

Buick Dealer Uses Tent—H. E. Pence, of the Pence Automobile Co., Minneapolis, Minn., distributor of Buick cars in the Northwest, last week started out a tent exhibit of the new Buick models to make all the state and county fairs of importance in the territory. The tent is 40 by 80 feet. Except at Huron, S. D., and Helena, Mont., where Mr. Pence will be personally, local dealers will handle the big exhibit. The first stop was at Grand Forks, N. D., July 28. The Pence company contracted for 390 Buick 1915 models with dealers the first day the exhibit was made in the Pence showrooms, Hennepin avenue and Eighth street.

Recent Incorporations in the Automobile Field

AUTOMOBILES AND PARTS

Indiana

INDIANAPOLIS—Metal Auto Parts Co.; capital, $50,000; to manufacture metal parts of automobiles, etc. Incorporators: B. E. Thompson, W. B. Austed, G. H. Scott.

MUNCIE—M. C. M. Motor Co.; capital, $10,000; to manufacture automobiles. Incorporators: W. M. Mathews, Luther Cobb, E. L. Morris.

Kentucky

COVINGTON—United States Motor Truck Co.; capital, $250,000. Incorporators: R. C. Stewart, B. Bramlage, M. H. McLean.

New York

NEW YORK CITY—Remington Motor Sales Co.; capital, $150,000; to deal in automobiles. Incorporators: Philo E. Remington, 30 Church St.; Carl W. Bliss, E. M. Kolstad.

NEW YORK CITY—Universal Advertising Autocar Co.; capital, $25,000. Incorporators: Antonio DeGiorgio, 107 Broad St.; Giulio J. Lusardi, Guiseppe Manara.

ROCHESTER—Pritchard-Lyon Motor Co.; capital, $25,000; to manufacture automobiles. Incorporators: Curtis B. Lyon, 47 Flower City Park; Paulina Pritchard, Albert R. Pritchard.

Ohio

CLEVELAND—Kelley Sales Co.; capital, $10,000; to deal in automobiles and parts. Incorporators: E. R. Cross, L. W. Kelley, F. T. Beaumont, D. V. Fisher, L. H. Luff.

CLEVELAND—Patterson Auto Carriage Co.; capital, $10,000; to deal in automobiles and accessories. Incorporators: Edna May Patterson, L. M. Westropp, R. J. Mariarity, C. C. McMobon, H. C. Patterson.

TOLEDO—Paige-Toledo Co.; capital, $20,000; to deal in all kinds of motor vehicles. Incorporators: C. L. Sturtevant, J. G. Eppens, H. D. Davis, F. Hofer, Jr.; C. L. Clapp.

PAINESVILLE—Vulcan Carriage Co.; capital, $1,000,000; to manufacture and deal in automobiles and other vehicles.

Pennsylvania

PITTSBURG—Pittsburg Motor Car Co.; capital, $100,000; to manufacture automobiles and all kinds of motors. Incorporators: J. M. Frere, H. J. Davis, G. Shearer.

GARAGES AND ACCESSORIES

Connecticut

STAMFORD—Enterprise Tire Shop; capital, $5,000; Incorporators: Claude L. Frost, Rupert C. King, John M. Carl, Harry J. Bond.

Indiana

SOUTH BEND—League Tire Co.; capital, $250,000; to deal in tires. Incorporators: W. P. Furey, R. J. Miller, M. Brung.

Kentucky

LOUISVILLE—Electric Garage Co.; capital, $25,000. Incorporators: George Bader, Frank S. Ouerbacker, J. Woodford Button.

Michigan

ADRIAN—Adrian Carburetor Co.; capital, $50,000; to deal in carburetors.

DETROIT—Wallace Shock Absorber Co.; capital, $5,000; to deal in shock absorbers. Incorporators: John E. Wallace, William J. Wallace, George C. McDonald.

New York

BROOKLYN—Rutledge Garage; capital, $10,000. Incorporators: Blanche V. Foulks, James E. Foulks, Jr., 1324 Dean St.; Oliver N. Sarvant.

NEW YORK CITY—Vehicle-Safeguard Instrument Co.; capital, $25,000; to manufacture safety devices for automobiles, etc. Incorporators: Junius A. Howe, 1269 Broadway; Frieda G. Howe, Junius J. Howe.

Ohio

CLEVELAND—Cuyahoga Tire & Supply Co.; capital, $10,000; to deal in tires and other automobile supplies. Incorporators: Louis Abrams, M. M. Gleichman, M. B. Abrams, M. Eckstein, N. B. Gordon.

CLEVELAND—General Rubber Goods Co.; capital, $50,000; to deal in all kinds of rubber goods. Incorporators: Griswold Wilson, L. H. Wallace, W. L. Hassenmueller, William G. Stuber, G. C. Sheidler.

TOLEDO—Wight Mfg. Co.; capital, $20,000; to manufacture automobile supplies. Incorporators: A. V. Wight, A. C. Faulkner, George Sace, Edward Scanlon, F. E. Calkins.

Oklahoma

CUSHING—New State Refining Co.; capital, $25,000; to deal in gasoline. Incorporators: T. J. Hughes, R. C. Jones, J. R. Travis, all of Cushing, and C. H. Travis, Coffeyville, Okla.

OKLAHOMA CITY—Emma Gasoline Co.; capital, $6,000; to deal in gasoline. Incorporators: W. A. Ledbetter, C. E. Franke, J. H. Gauthier, all of Oklahoma City.

Canada

TORONTO—Canadian Storage Battery Co.; capital, $40,000; to manufacture storage batteries.

CHANGE OF NAME AND CAPITAL

Ohio

AKRON—Miller Rubber Co.; capital increased from $1,000,000 to $2,000,000.

UNIVERSAL Annular Ball Bearings—The Schatz Mfg. Co., Poughkeepsie, N. Y., is offering a new type of annular ball bearing, Fig. 1, designed to meet the demands of the manufacturer of cyclecars and small automobiles, also for the needs of the accessory manufacturer. This bearing is known in the trade as the Universal.

The bearing is made with a solid steel cone, pressed steel cup rings and a soft steel outer jacket, which grips and holds the cup rings rigidly in place. The ends of the soft steel jacket are turned in in an angular position, as shown, against the cup rings, thereby reinforcing the cup rings and also giving a finish to the completed bearing.

These bearings are made from high-grade materials throughout. The cone and cup rings are carefully hardened and tempered and are guaranteed to carry the same load as standard bearings. Particular attention is called to the fact that although this bearing has all the advantages of an annular ball bearing, its construction is such that 70 per cent. radial thrust is obtained. Furthermore, it is claimed in this construction there is a three-point contact, making it practically impossible to break a ball under the most severe conditions. Owing to the fact that the universal is an annular bearing and positively non-adjustable, the assembling is less expensive than in other types. The manufacturer claims that this one feature alone makes the bearing particularly desirous in wheel construction. In this design the ball race in the cone and the O. D. dimensions only are ground, but the bore and other dimensions are kept within commercial limits. The bearings are made in standard sizes.

K-W Road Smoother—Several changes from the model announced at the first of the year are noted in the helical spring shock absorber which is manufactured by the K-W Ignition Co., Cleveland, O., and which is known as the K-W Road Smoother.

These shock absorbers, Fig. 2, are designed to be attached to the spring ends, replacing the shackles, both front and rear. There are several interesting features in the new model. First of which is an anti-rebound air chamber at the top which, it is said, effectually prevents the rebound of the spring. Then the anti-side motion links prevent side rocking and swaying when turning corners. The air piston is provided with an automatic lubricating pad and there is a dust shield enclosing the bottom of the mechanism. The springs are manufactured from electric-smelted chrome vanadium steel and phosphor bronze bushings are used throughout.

Bigger Rubber Preservative—A process by which it is stated that new rubber can be made to last for many years and by which the old rubber may be rejuvenated is offered by the Bigger Rubber Preservative Co., Inc., Buffalo, N. Y.

It is well known that rubber loses its life comparatively quickly because the chemicals needed to put it into the various forms for commercial uses, in time, cause it to disintegrate. But it is claimed that by proper chemical treatment that this chemical action can be prevented.

S. V. Truck Tire—A new pressed-on type of solid truck tire known as the improved S. V. has just been announced by the Goodyear Tire & Rubber Co. The feature of this tire is that there are no accessories needed, such as bands, keys, side flanges or bolts and there is no left or right side. The tread is flat, the base of corrugated channel section and more rubber is now used than previously. The weight of the tire now is less than the weight of the ordinary type with accessories, it is claimed.

Canvas Tread Tires—A rubberized canvas tire which is claimed to be exceedingly strong and immune to punctures, blowouts, etc., has been brought out by the Canvas Tread Tire Co., New York. The tire consists of 13 layers of rubberized canvas vulcanized together with an extra ply of rubber between each ply of canvas. The bead is of fiber. The maker claims unusual wearing qualities for this construction and adds that it shows excellent non-skid qualities. The prices range from $24.95 for the 30 by 3½-inch size to $60.60 for the 37 by 5-inch.

Polo Tire Alarm—A new model tire alarm, known as No. 14, has been introduced by the Polo Tire Alarm Co., Great Northern Bldg., Chicago, Ill. This alarm is intended to be screwed into place on the valve, replaces the ordinary cap and is so adjusted that should the pressure drop below the required amount a shrill and continuous alarm gives warning that the tire needs attention. A set of four costs $6, complete.

National Bar Spring—An unusual form of front spring is that shown in Fig. 3, in which a solid bar takes the place of the usual half-elliptic. This bar is pivoted to the frame at the front, and is supported at the rear by a scroll spring fastened to the frame. The axle is attached near the front of the bar so that the long end of the bar is supported by the spring and thus a lighter spring can be used.

It is stated that the shock or jolt occasioned by the wheels passing over uneven surfaces is transmitted in a line indicated by the arrow, and is automatically cushioned. When obstacles are encountered, the wheel momentarily stops, due to the fact that the operation of the bar swinging from its pivotal connection performs its function of receiving and transmitting shocks to the springs in a quicker time, thus permitting the wheel to pass over the obstruction without that sudden shock or jolt. After the car has passed over the obstruction, the action of the spring forces the bars into the normal position and prevents the vibration which always accompanies a shock when the car body is suspended upon the spring supports of the ordinary type.

Staon Tire Gauges—The Advance Specialty Co., Shinola Bldg., Rochester, N. Y., has recently brought out an im-

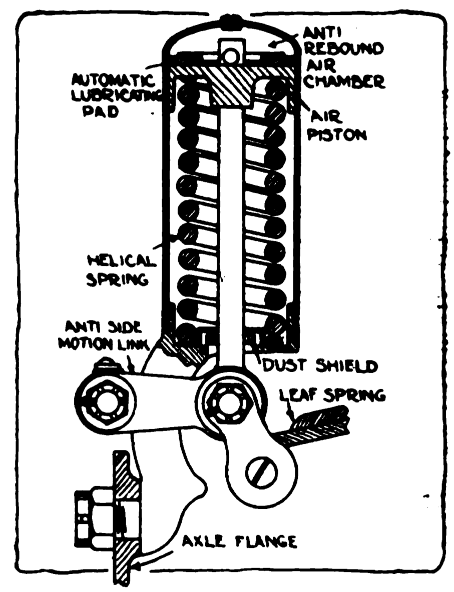

Fig. 2—New K-W Road Smoother with features plainly indicated

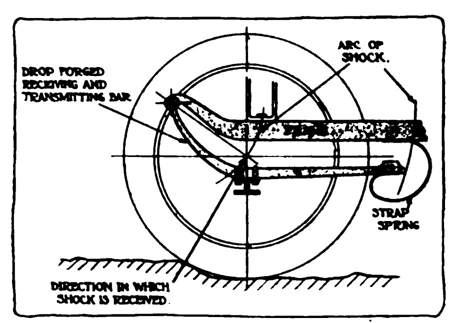

Fig. 3—National bar spring, in which a solid bar with a scroll spring at one end is used

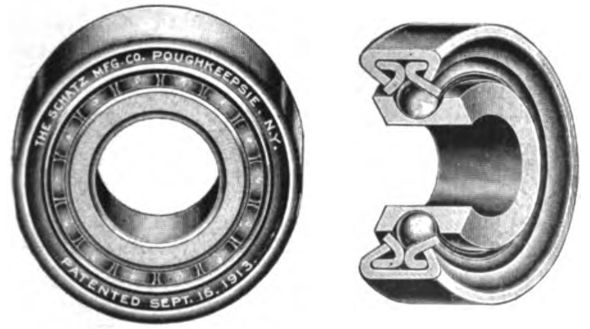

Fig. 1—Two views of the Universal annular ball bearings

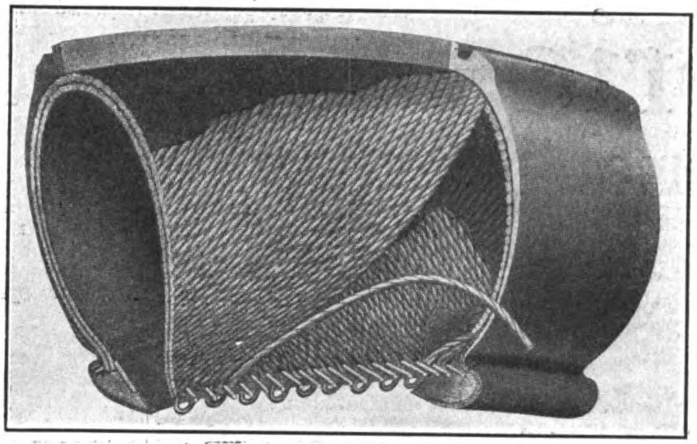

Fig. 4—Phantom view of Goodrich Silvertown Cord tire

proved form of tire gauge. A shut-off valve which is operated by the cover hinge pin in such a way that air enters the gauge tube only when the cover is open. When it is closed there is no pressure in the gauge tube and the pointer stands at zero. Because of this feature the gauge mechanism is relieved of continuous strain. The cost of a set of four gauges is $6, and the gauges are intended to remain in position except when the tires are being changed.

Goodrich Silvertown Cord Tire—There are many interesting features in the Cord tread tire recently brought out by the B. F. Goodrich Co., Akron, O. It is claimed that with the use of these tires that the 15 per cent. more horsepower is available for the propulsion of the car. In other words, this much more of the engine power is available because these tires offer less road resistance. This saving is due to the increased flexibility and resiliency of the cord construction. Looking at this feature from another angle—with the same gasoline consumption greater loads can be carried. It is said, that on a car that developed 15 horsepower at a certain speed, 800 pounds extra were carried without increasing the consumption of fuel. Also with the same load, the fuel consumption is reduced about 25 per cent. on the average, it is stated.

The increased resilience gives additional speed and makes the work of guiding the car much easier. Owing to the equality of tension in the cable cords, cars equipped with Silvertowns will coast much farther than cars with ordinary tires, it is stated.

Fifty per cent. reserve strength is claimed for these tires and also that the tires are immune from stone bruises. The cord construction and even tension make the Silvertowns extremely resilient. On hitting a stone the casing flexes easily and the shock is not felt on the inner body as in the old types.

It will be noted in Fig. 4, the cord tire, as its name implies, has a fabric made up of cotton cords or cables instead of a canvas cloth. The carcass of the tire is made up of a number of individual, long fiber cotton threads thoroughly impregnated with rubber under high pressure; these threads are then woven into a cord which is also impregnated with rubber. The finished cord is then woven over a form, in two layers, each layer of cord being separated by a layer of rubber. Every part of the cord is made and wound into the tire under an equal tension by specially designed automatic machinery in such a manner that all the internal strains are conveyed throughout, with no slack threads or overworked parts. Every part of the tire carries its share of the load and all parts work together as a unit it is stated.

An interesting test to show the relative merits of the two types of tires was recently made by the Goodrich company on a hill on South Main street, Akron, O. The car, a six-cylinder Peerless, was allowed to coast down this hill, equipped, first with ordinary canvas fabric tires, and then with Cord tires. The average grade was about 2 per cent. and the hill was 2,297 feet in length. Beginning with a standing start, no power being used, at the first .1-mile the speed of the car with fabric tires was 9 miles per hour and with Cord tires was 14; at the .2-mile these respective figures were 11.5 and 17; at the .3-mile, 11 and 17; at the .4-mile 8.5 and 16.5; and about 200 feet beyond this mark the car when fitted with ordinary tires stopped. At this same point the car, when equipped with Cord tires was running 13.5 miles per hour, and continued for 546 feet when it stopped on a slight up grade.

Double Spark Plug—In order to produce two sparks in the same cylinder at the same time the Power & Efficiency Co., Trenton, N. J., has brought out a double spark plug, shown in Fig. 5. This plug when connected with an ordinary plug causes the current to go to the gaps of both plugs and thus two sparks occur, thereby increasing flame propagation and hence power. The insulator is shaped to form a double V, the sides of the larger V being slightly concave and the smaller V being in the center and ending in a sharp point. This construction is said to cause the points to be cleaned by the gas. The insulator is carried to a point very near the spark gap in order to prevent any short circuit to the shell of the plug. The keeper B may be used to carry the current to ground after it has jumped the gap, and in this way the action is the same as an ordinary plug. By removing the keeper and attaching a wire in its place, the other end of the wire connecting with an ordinary plug, each plug will fire. The plug sells for $1.

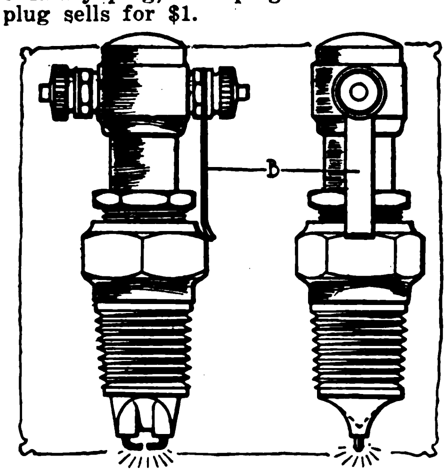

Fig. 5—Two views of Double spark plug

Ideal Gas Lighter—A simple device, Fig. 6, for lighting and controlling the acetylene lights from the dash has been brought out by the Ideal Brass Works, Indianapolis, Ind. It is easily installed, consisting merely of a gas regulating and controlling valve on the dash and some simple electric wiring to produce sparks at the burners when the gas is turned on.

An ordinary gas tank is used, a high-pressure gas tube running from the tank to the control valve on the dash. From here the gas passes to the regulating valve to the lamps, the same as in any system. Along side of the control handle is a small push button that is operated when the sparks are to be produced. Connected into the back of this switch is a lead running from the high-tension circuit. Closing the switch causes the current to flow between the spark gaps at the burners, and thus the lamps are lighted.

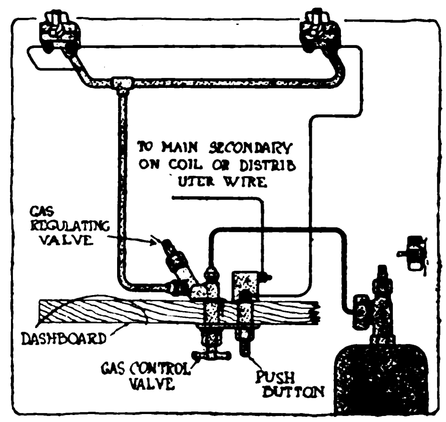

Fig. 6—Ideal gas lighter for acetylene systems

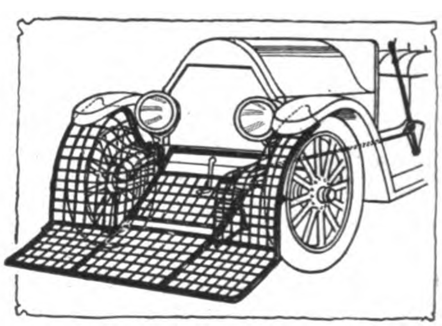

Fig. 7—The Standard fender, which may be raised or lowered from seat, depending on road conditions

The Standard Fender—An interesting invention that has recently been put upon the market is the Standard fender, Fig. 7. It is designed to protect pedestrians from being run over, by motor vehicles, and trucks especially, and yet not interfere with maneuvering of the machine or its progress under varying road conditions.

The Standard fender is easily manipulated by the driver by a lever which allows him to raise the fender slightly when traveling over rough roads, or a full movement of the lever folds the fender up. The fender when lowered in position is 2.5 inches from the ground.

Standard fenders are constructed for all sizes and styles of machines and are built from channel and angle steel, which is latticed and securely riveted. Every bolt is fastened with a lock washer.

Vol. XXX New York—Thursday, August 6, 1914—Chicago No. 6

The Automobile

Bird's-eye view of an industrial city where the facilities for manufacturing, shipping and storing are combined—the buildings, yards and docks of the Bush Terminal Co.

Terminal City—A Triangle of Efficiency

Combines Facilities for Manufacturing, Storing and Shipping in One Huge Industrial Settlement

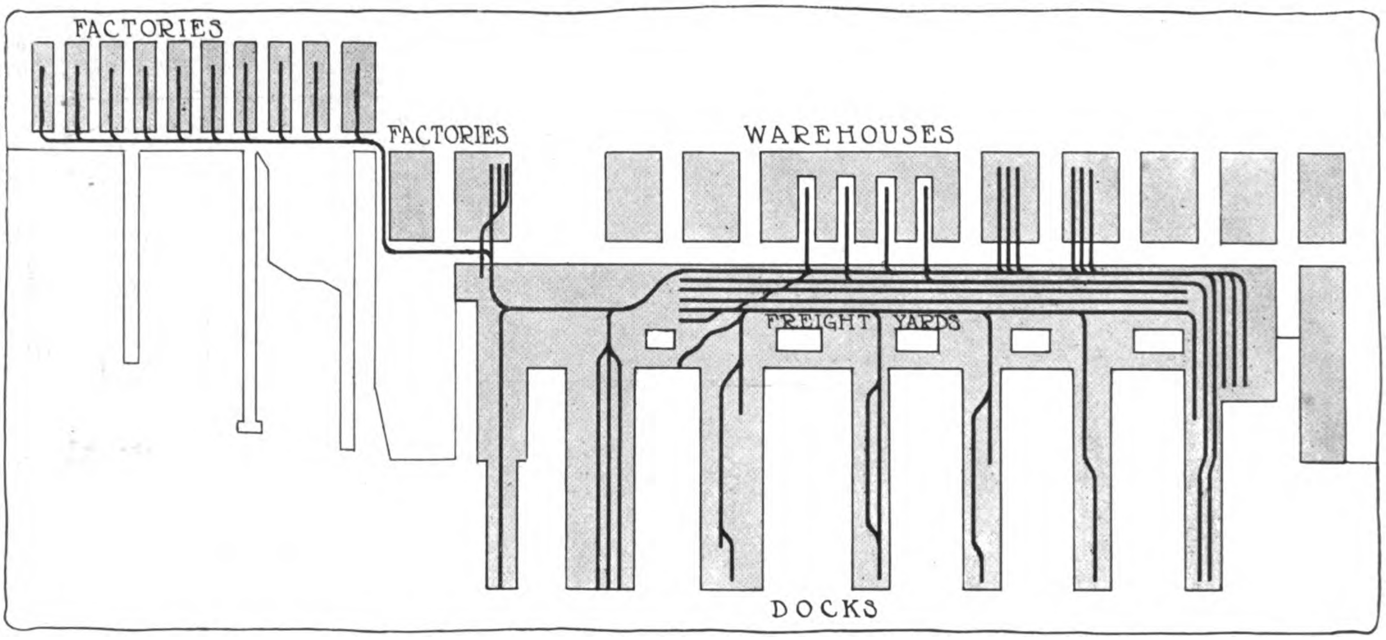
By J. Edward Schipper

THE operation of a manufacturing city along the lines of an office building is accomplished. It is not a looked-for desire but an actual business reality. True, such an industrial city occupies more than a city block—it is not one building but a dozen—yet the entire plant is governed through one administration. Renting space in such a city is much the same as renting a flat. You get heat, water and a dozen other service features thrown in. Your rent pays for floor space, heat, the use of the shipping facilities, fire protection, storage, etc.

As a manufacturer in such an industrial city you are relieved of factory cares, you are provided with power at a lower rate and a hundred and one other advantages are yours at a minimum cost.

Universal service for every manufacturer; one set of elevators arranged for the convenience of all the occupants of the huge buildings; a complete freight yard solely devoted to the use of the manufacturers; one set of motor trucks to convey the goods of all companies; one general shipping department to relieve the occupants of the bothers of routing their goods—all this is accomplished in the industrial city which is operated along the lines of a New York skyscraper.

Once the manufacturer has placed his goods in a packing case his responsibilities cease in the same manner as if he had placed a letter in a mail chute. He knows that the machinery of the city will place the goods upon an elevator, carry them to a loading platform and even place them on the car of a line which enters the territory to which he is ship-



Layout of the buildings, freight yards and docks of the terminal city designed to render quick shipping service to the occupants

ping. If he is shipping to a foreign country, the steamships which dock at the desired port also dock at the piers of this industrial city. His goods will find their way into the proper hold and across the seas to their destination.

Elasticity of Space

Should he be using 5,000 feet of manufacturing space and then suddenly through the securing of a large order desire to double or treble that amount, the space is there. His manufacturing elasticity is unbounded. He need not worry over the building of additions to his factory.

He need not bother about the space for the dead storage of his product, it is supplied. Enormous warehouses for the use of the city's manufacturers provide the space for the storage of his goods. It is not necessary to pay the same rent or the interest on the same invested capital for storage space as for manufacturing area. Overhead is cut to the bone, for the manufacturer need only pay for the space that he uses. He need only employ the number of men that he needs and he need not ship his goods through the traffic-laden streets of a metropolis.

The factory is at the terminal. The connecting link is removed and the chain connecting factory to purchaser is shortened. Attention is not distracted by the harrowing details of tracing freight shipments because the terminal city employs its own tracers and sees the cars safely on their way. Efficiency in handling manufactured products has now passed beyond the point where it merely applies while the material is passing through the plant. After an article has been made it is really not complete until it has been put into the hands of the user. If it costs too much in money or time to put the article into the users' hands, then the saving which has been effected by the use of efficient production methods is lost.

Three great problems beset the manufacturer. He must have space in which to manufacture, he must have efficient shipping facilities and he must have the space to store his goods whenever necessary. The highest degree of efficiency in the handling of the manufactured product is not attained until there is no lost time, money or motion.

Manufacturing

The most efficient manufacturing plant is that in which the floor space held by the manufacturer is just sufficient to meet his needs. He must be neither crowded nor must he have an excessive amount of room. But the quantity turned out by a factory varies from time to time in order to meet the demand. Therefore, in order to take care of the maximum condition and at the same time not to have too much dead space on the minimum, the factory space should be elastic. The efficiency factor in the manufacturing plant as far as space is concerned is in its elasticity.

Shipping

In shipping the utmost economy is obtained when the number of steps between the maker of the article and its user are a minimum. When the factory is at the railroad terminal this desired condition is obtained. When the manufacturer of an article is located in a large city, he has to depend on sending his goods through the city streets before he places them in the hands of the accredited agents of a railroad. He is subject to the delays of traffic, loading and unloading. The difference between first putting the goods on a truck and putting them directly on the freight car means thousands of dollars annually to a large manufacturer and for this reason many are obliged to forego the advantages of being near a good source of labor supply in order to be in a position to secure a railroad siding.

Storing

For a manufacturer to store his goods economically the warehouse must be near the factory. This will reduce the carrying charges between the factory and the warehouse. The storage place must also, for maximum economy, be at the shipping terminal because it must be possible to ship directly from the storing place without intermediate handling.

The only way in which these conditions can be met is in the concentration of the factory, warehouse and shipping terminal at one point. This proposition has been met in New York in this manner and has been taken advantage of by 200 manufacturers who have centered in a terminal city in which there is unlimited space for manufacturing and storing and which is at the same time a terminal shipping point for every railroad line that enters the city and for vessels which reach every country in the world.

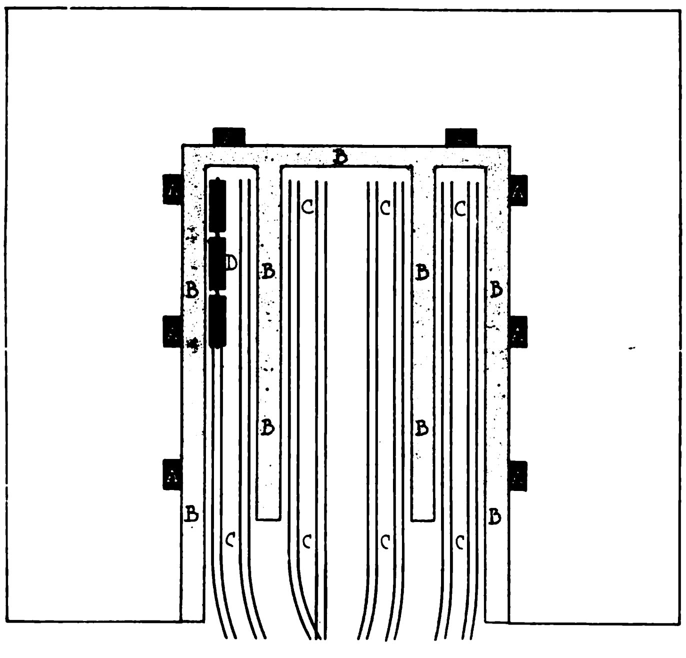
Short cuts in routing goods through factories have resulted in the saving of thousands of dollars. The only reason that short cuts in the balance of the handling of goods have not been made is because they require an undertaking so vast that it is out of the power of any but the largest concerns. The idea of a terminal city in which a manufacturer can vary the amount of floor space he requires and at the same time be in close touch with storing and terminal facilities has solved the problem of cutting down overhead for these two hundred manufacturers and the same idea could be adopted in other cities.

By the construction of huge manufacturing buildings the greatest elasticity is given the manufacturer. He can quickly secure the space to meet his largest demands should they come suddenly. He can secure any amount of light and power at a cost that would be much lower than were he to secure it outside or were he to attempt to generate it himself. When the storage warehouses are close at hand no dead space has to be carried for the storing of goods and yet he can store as much or as little as he likes. There is at his disposal a flexible three-unit plant which responds to the touch of the throttle of demand in the same manner that a high-powered car leaps forward to meet the needs of the moment.

Overhead Expenses Cut

When selecting the location for an industrial plant broad consideration must be given to the problems of machinery, power, labor and all the factors that enter into the manufacture and marketing of the output. With the exception of high rents and difficulties in reaching good shipping facilities a large city offers big advantages in all of these. With the removal of these two objections an enormous cut in the overhead expenses of a city plant can be effected.

It is not surprising that the banding together for a number of manufacturers would result in the cutting of expenses for the individual. The same principle has been used in the purchase of other commodities than factory requirements. Housewives have found that where several came together and purchased in quantities much more advantageous prices have resulted. And in this instance where the plan was limited because of the few necessities required by every one involved in the plan it would not be limited in the instance of manufacturers bcause they all require space, light, heat, power, labor and shipping facilities. They all need room for future requirements and quick postal and telegraph service.



Plan view of the mammoth U-shaped factory buildings, showing how the elevators A communicate with the loading platforms B. The freight trains D can enter the enclosure and reach all parts of the building by means of the tracks C. There are frequent switchings and sidings to facilitate rapid handling of the cars

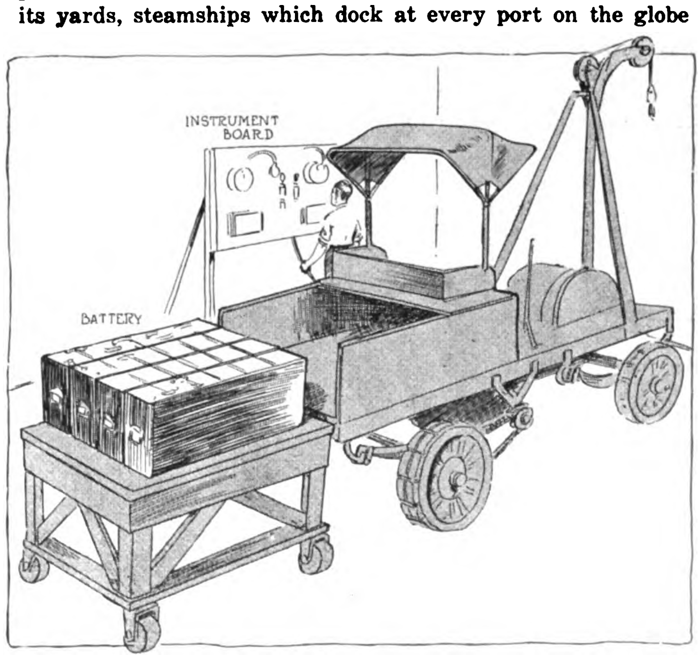
There is not one of these requirements which is not secured more cheaply if bought in large quantities and then distributed to the individual according to his needs. In the specific case of labor, the location of such a concentrated industrial plant within the limits of a large city puts every manufacturer in touch with an abundant supply of labor that will be much better trained to his particular class of work than that which he would find in the country.

New York is not alone however in the requirements of terminal service. About a year and a half ago, the Philadelphia Team Owners' Assn. brought an action before the Pennsylvania Railroad Commission looking to get improved conditions at the different freight terminals in that city. At the Convention of the National Team Owners' Assn. held in Minneapolis last June, the matter was brought up and it was decided to make the subject of congestion at terminals a national issue, and since that time the local associations in several of the large cities throughout the United States have petitioned the Interstate Commerce Commission to grant them relief.

Package freight moves through the New York terminals in quantity and variety greater than through any other terminals in the United States. This bears a direct relation to the population which aggregates more than 5,000,000 and to the extensive manufacturing and other industries which are only to be found in the first city of America. The physical handling of this freight presents a task so stupendous, that but for the doing of it men would say it were impossible. To cope with this situation, the freight terminals must be spread over a wide area, or else these terminals must be conducted with an efficiency of the highest order. The answer to this is a terminal such as the Bush Terminal in New York.

Community in Industry

Covering 250 acres of ground and embracing within this wide area the most modern facilities to meet each of these three great problems this gigantic terminal city stands as concrete evidence that the community principle can be carried to the heart of industrial questions. The enterprise stands alone and independent. The outside city streets need not carry so much as an ounce of the products of the 200 factories which are already represented within its broad expanse. The freight cars of every line in the country are in its yards, steamships which dock at every port on the globe



One of the utility battery crane trucks made use of at the terminal city, showing how it is relieved of its battery by means of a rolling table of the proper height. These battery crane trucks not only lift heavy loads but carry trains and trailers about the city yards

Specimen of steel reinforced concrete factory building at Bush Terminal. Tenant may have 140,000 square feet of space on one floor of this building

are moored to its huge piers. The employees and their families now supported by terminal represent a population of 50,000. The plant was organized in 1902 by Irving T. Bush to remove manufacturing from the crowded streets of Manhattan.

In meeting the three requirements of providing manufacturing space, shipping facilities and storage warehouses, the Bush Terminal Co. has planned for the future. Everything is done on so vast a scale that for some years it is impossible to foresee the present and proposed facilities outgrown. There are 5,000,000 square feet of floor space which can be utilized for manufacturing purposes. This space is contained in ten concrete and steel buildings and there is plenty of room for thirty more of these buildings of the same size. These will be built as they are needed. Eight of the buildings which now stand are six stories in height and the other two are eight stories.

The plant occupies a long rectangular space extending along the waters of the upper bay. It extends from 29th street South Brooklyn to 52nd street, a distance of 23 blocks in length and, neglecting the seven 1,400-foot piers which project from the rectangle like the prongs of a rake, it has a depth of two city blocks. It is located on the eastern shore of New York bay. A general idea of the shape of the plant and its relation to New York City is given on page 255.

One of the covered docks at Bush Terminal. Ships on one side deliver the freight, cars on other side move it to its destination without the use of the city streets

The fundamentals of success for a factory site are that it must be near the source of labor supply, it must be handy to the market for raw material and it must be able to reach the consumer at the lowest possible price and in the least possible time.

Labor Supply Unlimited

Within the 5-cent fare zone of the Bush Terminal there are 5,000,000 people. The supply of labor is unlimited. Ferries, elevated roads, subway and surface cars are handy and radiate in all directions from terminal plant like the veins of a leaf. Thus the home accommodations of those who labor at the terminal are practically without bound. Restaurants abound in the neighborhood and in one of the buildings one is provided at which good food can be secured at reasonable prices. There are five mail deliveries a day and there is a post office located in the plant.

A manufacturer can secure as much space as he needs. Subdivisions as low as 5,000 square feet can be arranged for and the rental is 30 cents per square foot for any but the top and ground floors on which the rental runs 35 cents a square foot. This rental price does not only mean that space is provided but in addition all the facilities of the terminal for heat, fire protection, elevator service, transportation service and watchmen are included.

In daytime there is no possibility of a want of light. The U-shaped buildings permit of light on every side as well as in the center and at night the electric current for lighting is supplied by the dynamos of the Bush company at little more than cost. The hot-water heat supplied by the plant in winter is sufficient to keep any room in any f the buildings at the desired temperature.

The fire protection is a big factor in the economy of the plant because it means reduced insurance. The rates are approximately 10 cents per $100 in the New England and Mutual companies and 20 cents per $100 in the line companies. It cost the terminal company $1,000,000 to install the fire protection system. There are 220 miles of piping leading to 225,000 sprinkler heads. The electric wiring totals a length of 175 miles. A force is maintained to inspect the fire alarm apparatus and maintain it at its highest efficiency at all times. When a fire breaks out the high temperature starts the water from the sprinkler head and at the same time automatically turns in an alarm which is responded to by the trained fire force. In a recent fire which occurred on one of the lower floors of a building, a number of girls located at the windows of the upper floors amused themselves by observing the crowd which had gathered below. This in spite of the fact that smoke was pouring from the windows of the rooms in which the fire was burning.

Eight Automobile Firms

Eight manufacturers of automobile supplies and accessories have already made their headquarters in these buildings and scores of other industries which are here represented are closely allied to the automobile industry. The Eisemann magneto company has its plant here as have also the Emil Grossman Mfg. Co.; the Jones speedometer; New York and New Jersey Lubricant Co.; Oil Products Co.; Tagliabue Mfg. Co. maker of the well-known viscosity meters; Sears-Cross, manufacturer of speedometers, and the Wagner Electric Mfg. Co. Besides these there are manufacturers of all kinds of engineers' supplies, bolts, nuts, measuring instruments, etc.

Freight sidings and loading platforms surrounded by Bush factory

Shipping Arrangements

The moment a packing case leaves the door of the factory it is taken under the care of the Bush Terminal and the owner need have no further fears for its safe and speedy transmission. A Bush employee places the packing case on a Bush handtruck, wheels it to the elevator and loads it thereon. It is taken to the ground floor and carried to the loading platform by Bush men. The goods are then placed on a car of the line over which they are to be shipped. The car is then hauled by a Bush electric locomotive to the car floats and there the car is loaded on a Bush barge and carried to the proper railroad terminal and sent on its way. All this is without charge, being included in the rent.

Congestion of the city streets is absolutely avoided for the area of the Bush plant is so great that nothing like a jam of the streets occurs. There are eighty elevators at the disposal of the tenants, each is capable of 6,000 pounds and each has an area of 88 square feet, giving a total carrying capacity of 480,000 pounds per trip.

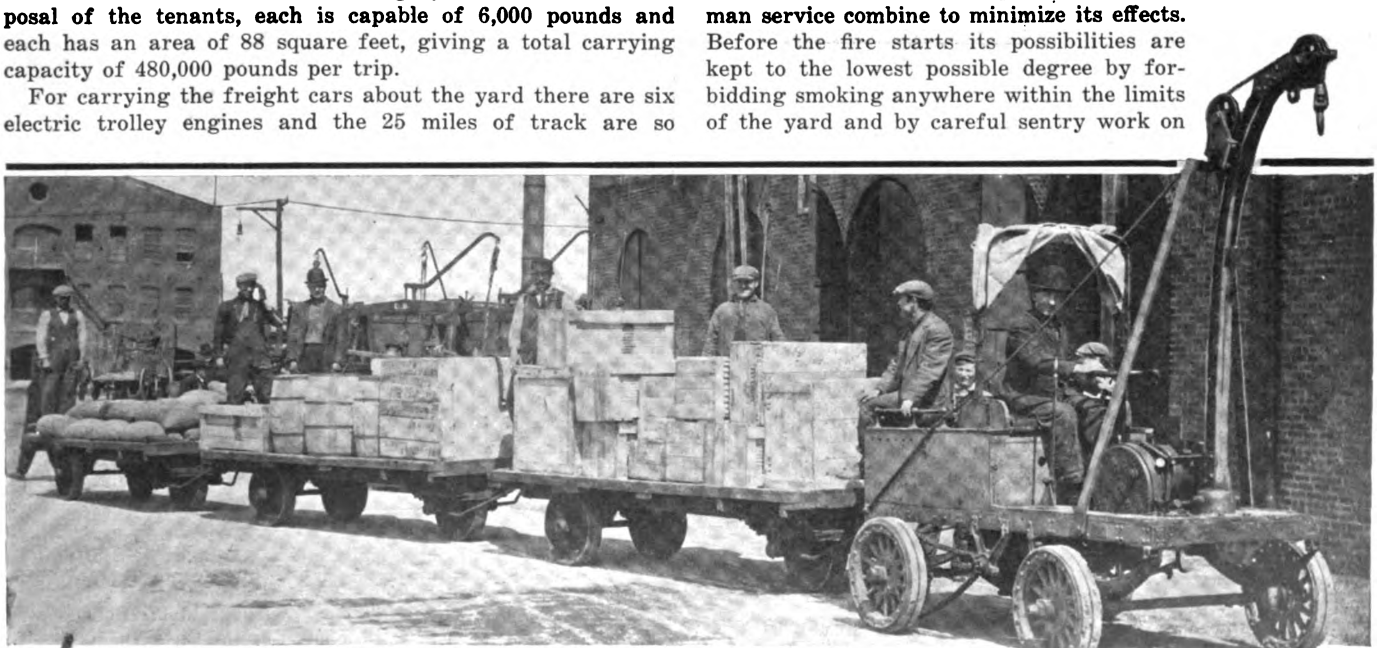
For carrying the freight cars about the yard there are six electric trolley engines and the 25 miles of track are so placed that there is not a point in the yard that cannot be easily reached. Frequent switches and sidings also help in the efficient handling of the transportation. Another factor in the efficiency of the handling of goods is in the use of four electric battery crane trucks. These tow trains of trailers and are not only useful for this work but in the actual lifting which is accomplished by the small crane attached to the front end of the truck. These trucks are inspected every noon and are ready for the men who operate them at the close of the lunch hour.

When the trucks are brought into the inspection and charging station at the noon hour they are lined up in the garage and a reading is taken on the ammeter to determine if the batteries still have a sufficient charge to last during the afternoon. By this system of two inspections a day these little units are maintained in a state of constant efficiency and perform a valuable work in the handling of goods about the yard.

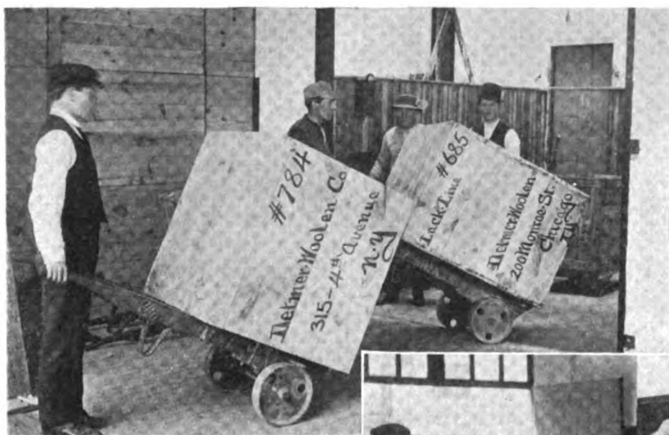
Storage in 130 Warehouses

The cost of storage in the warehouses of the Bush terminal is a minimum on account of the small amount of handling required to get the goods in and out of the storage warehouses and on account of the vast space provided. There are 130 warehouses of various sizes. In these, goods of any nature can be taken care of and the cost will depend on the bulk and on the nature of the risk the company assumes in taking charge of them.

The warehouses are also of concrete and steel construction and in addition to the inherent fire-proof qualities of this type of building, the sprinkler system taps every nook and corner. The fire protection accorded the goods is complete in both curative and preventive measures. After a fire has broken out the automatic sprinkler and alarm and the watchman service combine to minimize its effects. Before the fire starts its possibilities are kept to the lowest possible degree by forbidding smoking anywhere within the limits of the yard and by careful sentry work on



Battery crane truck for handling light freight at Bush Terminal. Giant warehouse in background



the part of the department in charge of the policing of the terminal.

Organization Is Complete

The internal arrangements of a plant of this size are as complete as those of a well-governed municipality. The wheels of industrial efficiency must not be clogged and at the present time the Bush company employs 2,000 men to see that they are not. The police and fire departments are trained to the minute and the adminstration organization made up of the heads of the various departments and the company officers eliminates the lost motion in the handling of the goods through the facilities of the yard by frequent meetings in which the interlocking duties of the departments are discussed.

The tenants of the Bush Terminal Co. are not the only ones who make use of the facilities for shipping which are found at its plant. Although the company operates its own railroad, primarily to facilitate the handling of freight about the terminal, there are still a number of other manufacturers who make use of it. There is a track delivery yard with a capacity of 200 cars for this business.

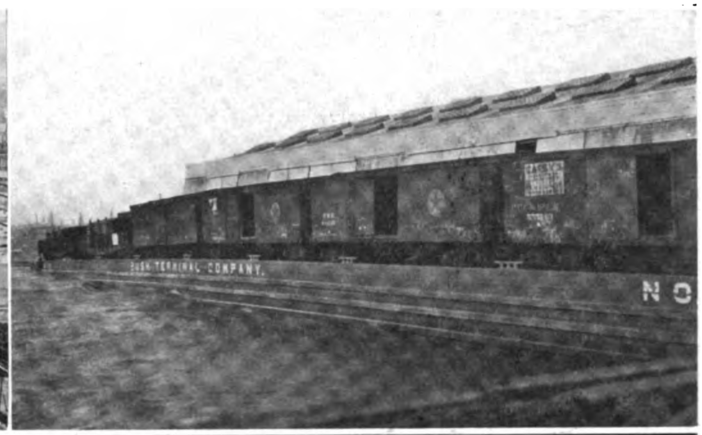
There are twenty steamship lines which now use the Bush terminal for berthing their vessels and besides being the accredited agents of these lines, the offices at the terminal are the American headquarters for many of the freight lines. Steamships are now docking at the piers at the rate of 750 a year and the large new double-decked pier, 1,400 feet long by 270 feet wide and 50 feet high, is the largest in the United States. It is to reach these facilities that outside concerns who are not tenants of the terminal make use of the yard service.

The social welfare side of this giant organization is not neglected. There is a garden for the children of the employees which is carefully inclosed by a high barbed wire fence to protect it from harm. In this the children are instructed in gardening. There is a loan organization from which employees can borrow at the rate of 6 per cent. annually for the purpose of meeting old debts, to purchase furniture, for illness, rent or vacation. In the last 3 years $3,000 has been loaned to 140 employees. The average loan is $20 and the maximum except in cases of extreme misfortune, is twice the weekly pay of the borrower.

Ten Departmental Heads

The administration consists of a president, four vice-presidents, secretary, treasurer and board of directors constituting the administration board. The departments of the plant are: finance, docks, warehouses, factory buildings, railroad yard, freight, floating equipment, legal, educational and social service. All are under specially qualified superintendents who are supreme in their respective spheres, subject only to orders from the administrative council. The legal department embraces a number of lawyers, one of them resident who looks after leases, claims, etc. The educational and social service are under directors. The former edits and publishes the plant's magazine, lectures before business bodies, handles advertising publicity, etc., and the latter department looks after welfare of employees and their children. The Bush Terminal Aid Society, with rooms in the Terminal Building, No. 19, is another feature of interest. There is a well-equipped meeting room, billiard and pool room and bowling alleys. The administrative board or council passes on everything of a business

From factory to destination—This series of illustrations shows how the packing case is taken in charge by the Bush Terminal Co., placed on one of the elevators, thence to a loading platform and into the freight train which finally carries it to the desired point, relieving the shipper of all anxiety



Railroad yard at Bush Terminal, which accommodates 2,000 freight cars. Freight cars on float to be carried to proper railroad terminal

character. The police and fire departments come under jurisdiction of the plant superintendents.

Justifies Community Principle

The terminal is only another adaptation of the community principle which has been advocated by students of political and social economy for decades. But it is a more sensible use of the principle than any of the so-called communities which have been founded on the principle of joint work. Here, there is no intermingling of those whose interests are not in common and each concern represented gives no more than a fair return for what it receives.

There is no support of the idle members of the community by those who labor more diligently, but there is a blending of interests in the cause of common efficiency which would not be possible with the detached scheme which this terminal replaces. The triangle is complete. It is an equilateral triangle, too, in every sense of the word, the requisites for each of the three branches, manufacturing, shipping and storing, being given their required amount of space without one overlapping the other. For, to what end would it be if the floor space and power for manufacturing were provided, and if, on the other hand, sufficient freight cars could not be accommodated to take away the products turned out?

The same applies to storing. With the 130 warehouses there is never a question of their being overtaxed. Goods can be kept at the temperature which they require to await the arrival of the steamship to bear them away or they can be kept at the warehouses indefinitely and there is plenty of room to accommodate the needs of the outside customers who make use of the facilities of the Bush terminal.

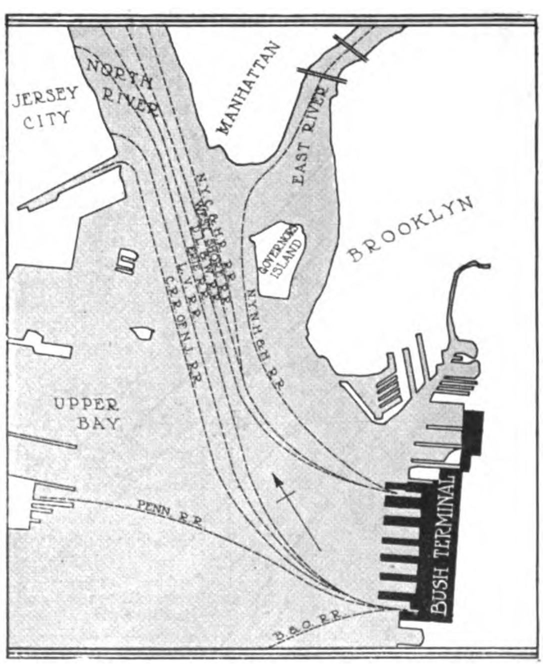
Bush Facts

¶ The Bush Terminal Co. is 14 years old.
It extends over an area of 250 acres.
It is located in South Brooklyn, N. Y.
There are now ten factory buildings.
Its industries support 50,000 people.
There will eventually be forty buildings.

¶ It has 5,000,000 square feet of factory space.
The buildings are all of concrete and steel.
There are seven 1400-foot piers now completed.
Within a 5-cent fare are 5,000,000 people.
In the yards there are 25 miles of track.

¶ It has a capacity of 2,000 standard freight cars.
It is protected by 220 miles of sprinkler pipe.
There are 225,000 sprinkler heads in the plant.
Electric automatic alarm wire totals 175 miles.
Steamships from its docks reach every port.

¶ There are 130 storage warehouses of all sizes.



Map showing the location of the Bush Terminal in relation to Manhattan and Brooklyn. The huge piers extend 1,400 feet into the waters of the upper bay, docking vessels from all ports

Hay Started Terminal

The history of the terminal is unique. Realizing the advantages of South Brooklyn for a terminal point because of its great natural marine advantages and because through its use the traffic congestion in the city streets would be avoided, the founder, Irving T. Bush, organized the terminal and then went out West and bought hay, ordering it to be sent to the Bush Terminal.

The railroads had never heard of this and refused to take the freight shipments for a while, but the orders to have hay shipped to the Bush Terminal continued, and finally the shipments were accepted. It is stated that Mr. Bush sold his hay at a profit.

After the shipments continued for a while the Bush company arranged with the railroad companies to operate its own barges, bringing to the railroad terminals freight consignments to be shipped over their lines.

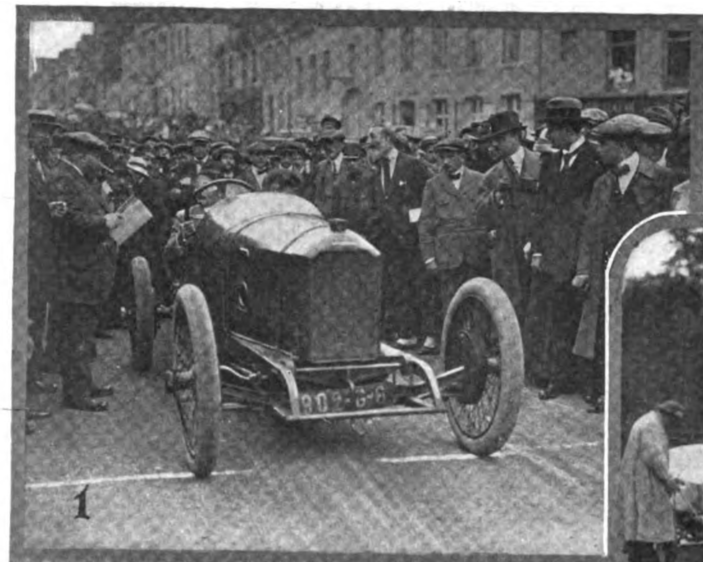
It was then but a step toward the promotion of the manufacturing and storing end of the business. These have kept pace with the shipping and the result has been a well-balanced plant.

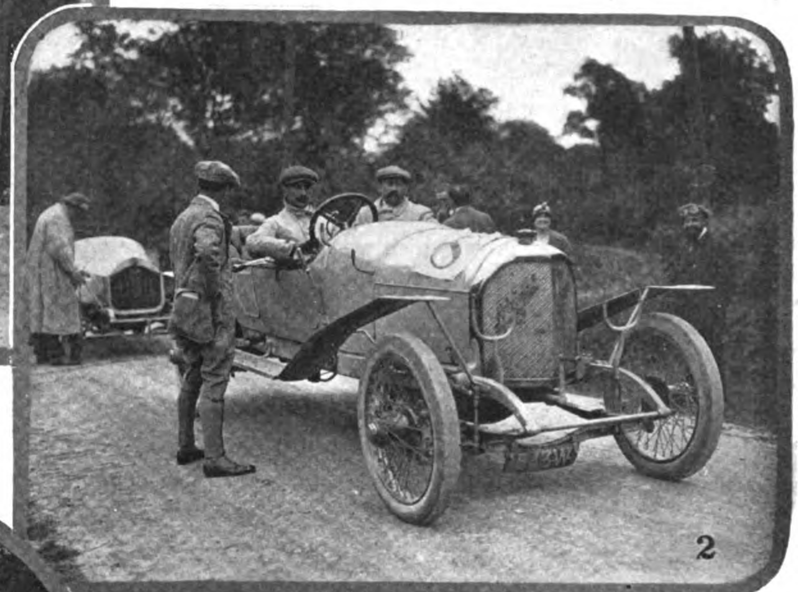
Room for Future Growth

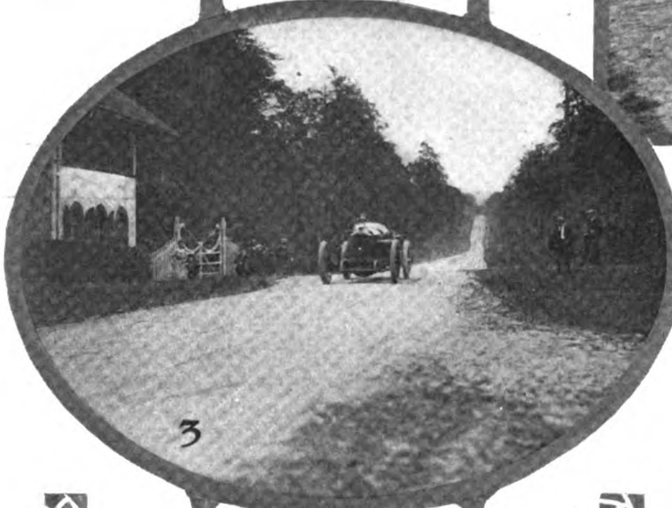
In laying out the plant the future has been considered as well as the present. There is enough property owned by the enterprise to erect many times the buildings which are now standing and the docking and storing facilities will grow with the increase in factory space. The railroad yards, which are a complete system in themselves, can expand beyond the limits of the present plant to such an extent that no fears for the future are held by the terminal officers.

Grand Prix Peugeot

Attains This Average Sp







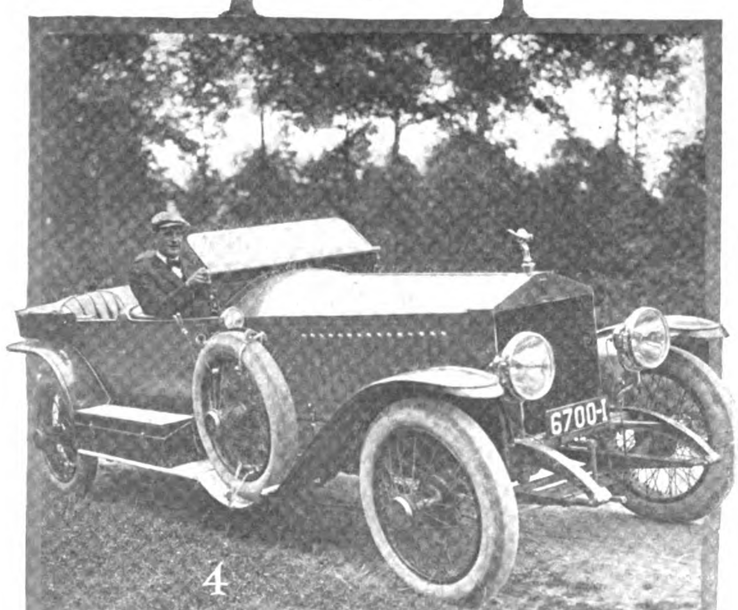
1—Grand Prix Peugeot starting the hillclimb at Boulogne
2—Vier in the Abadal, one of the fastest of the touring cars
3—Grand Prix Peugeot averaging 107½ miles per hour

BOULOGNE-SUR-MER, July 25—With a piston displacement of only 274.6 cubic inches, it has been possible to attain an average speed of 107 1-2 miles an hour over a 4.3 miles straightaway, the latter portion of this distance being covered at 112 miles an hour, to cover 3 kilometers standing at an average of 90.4 miles an hour, and to climb a mile hill, standing start, with several bends, in 1 minute 1-5 second. These performances were put up by one of the 274.6 cubic inch Grand Prix Peugeots which took part in the race at Lyons. It was the only car of its class in the meeting and naturally defeated all comers. In addition, it broke four year-old records held by the late Camille Jenatzy with a racing machine of 1,342 cubic inches piston displacement.

Knight-Motored Panhard Does Well

In the touring car section wonderfully good work was done by Panhard-Levassor, with Knight motor, which defeated all comers and bettered the racing car times with the exception of the Grand Prix Peugeot. Over the 1.86 mile course the average speed was 72.7 miles an hour, attained with a standing start. On the 4.34-mile course, flying start, the average was 82.5 miles an hour. The car is the Panhard-Levassor 35-horsepower model with a four cylinder Knight motor of 125 by 150 millimeters bore and stroke.

America was represented in this meeting by Johnny Aitkins, who drove a Rolls Royce touring car belonging to Charles Faroux. He finished fourth in the 4.34-mile trial.



4—Johnny Aitkins on Rolls Royce owned by Charles Faroux, which won first prize in the elegance competition

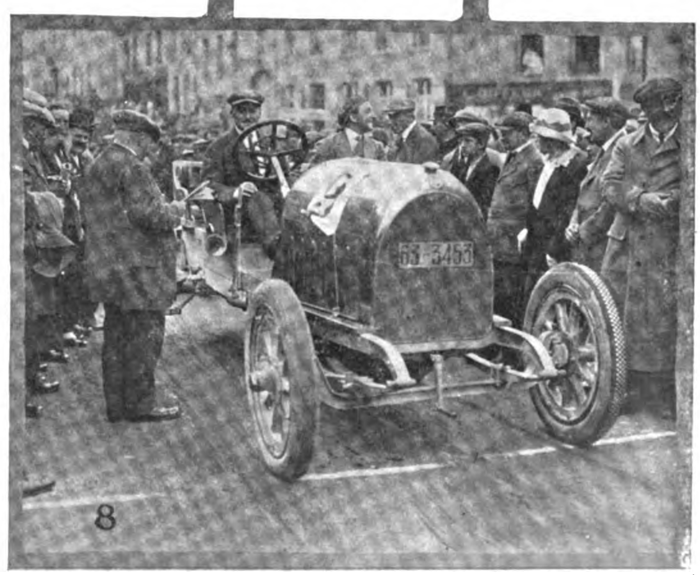
The French Grand Prix at Lyons did not allow the public to appreciate the speed possibilities of these new 274.6 cubic inch creations. **The average of 65.5 miles an hour was alone looked at, the fact being lost sight of that the course was of such a winding nature as to make speed impossible.**



8—Leduc on the Spa, one of the fastest of the racing cars in the competitions held at Boulogne-sur-Mer

Rapid Flame Propagation the Aim in Plug Location

The Automobile Engineers' Forum

F. E. Moskovics Takes Exception to Statements in "The Autocar"—Not a Matter of Number or Location of Plugs but of Raising Effective Pressure of the Cylinders as Rapidly as Possible

INDIANAPOLIS, IND.—Editor THE AUTOMOBILE:—In THE AUTOMOBILE for July 16, page 123, you give considerable prominence to a line of experiments and resultant curves by C. F. Dendy Marshall on the subject of location of spark plugs and the effect on power development; as reported in *The Autocar*. I read the report very carefully and was absolutely astounded at the results obtained until I reached practically the last part of the article in the paragraph headed Two Plugs are Unnecessary, where I find the little joker, which lies in the paragraph—"The engine I experimented with was of the fashionable type with all the valves on one side."

Flame Propagation Rapidity the Problem

Now, is it possible that a writer capable of attracting the technical attention of *The Autocar* should have to even experiment on a proposition of this sort. The matter is not one of spark plug location nor number of spark plugs, but the old, old problem of rapidity of flame propagation. It is so childlike in its simplicity, the principles involved are so elementary, that it hardly seems possible that they are not perfectly manifest to everyone in the profession.

Shape of Motor an Important Factor

Of course, locating two spark plugs over the valves of an L-head motor will make no appreciable difference, but placing them over the valves of a T-head motor would certainly make a great difference. Also, had Mr. Marshall made his experiments by placing his plug or plugs in the center of his cylinders rather than over the valves, he might have found some results which would have surprised him.

Center of Flame Area for Plug Location

We might refer him to the Sunbeam factory in England, which locates the single spark plug in the passage between the valve ports and the cylinder bore to get it as near as possible to the center of the flame area, or he might inquire of the various designers of the Knight motored cars, who locate their spark plugs directly in the center of their combustion chambers for the same reason and all of them have the single purpose of getting as rapid flame propagation as possible.

Raising Effective Pressure of Cylinders

The problem is so clear that it would seem at this late date it was unnecessary to again point out that it is not a matter of where the plug is located nor how many plugs are used so much as the fact that the result to be attained is that of raising the effective pressure of the cylinders as rapidly as possible and this certainly is accompanied by rapidity of flame propagation, and rapidity of flame propagation is accelerated by simultaneous ignition of the charge at points widely separated.

This also answers the last paragraph of the writer in which he says that "it seems that the double plug arrangement has much more effect when the valves are on opposite sides than when they are on the same." Then again he draws an erroneous conclusion when he says "owing probably to the two points of ignition being farther apart." I beg to say that there is no probability or question as to the reasons involved. It has been proven too often on the dynamometer, and the manograph clearly shows the increased pressure of the two-point ignition when the plugs are located as far apart as possible.

Symmetry of Firing Does Not Affect Power

The closing paragraph states he credits the advantage of two-point ignition on T-head motors "partly to the fact that the charge is symmetrically fired." I believe it is safe to say that the symmetry of the firing of the charge has absolutely nothing whatever to do with the increased pressure and the resultant increased power.—F. E. MOSKOVICS, Commercial Manager, Nordyke & Marmon Co.

Car of the Future Will Be Greatly Simplified

DETROIT, MICH.—Editor THE AUTOMOBILE:—The whole construction of the present day automobile (excepting perhaps the body and wheels), is rotten. I know I am stacking up against some pretty clever designers but tell me what has been done in the automobile as we now have it, outside of the perfection of details that was not in the little $650 Olds of the early 90s, or the big single-cylinder Winton of the same period. I will say there has been not one radical improvement or change.

Look back in the early stage of industry, when steam wore the crown and when Charles Duryea would argue with everyone that would argue with him that the internal combustion engine was the coming motor power. In those days Duryea, Olds and Alexander Winton were, you might say, the Master Minds. They are the ones who built the present automobile when it started.

Addition, Complication and Results

Since then we have added improvements, of course. We have also added cylinders, added gears, added magnetos, added expense, added complication, until it compares favorably with the first-class battleship, but always the same old machine. True, we get somewhat better results, but why wouldn't we? Haven't we been working on the same old thing long enough? And, haven't we added enough to get something?

The Car of the Future

Now let me tell you what the motor vehicle will be not 50 years hence but 25 years from now. You can call it imagination if you wish, a dream or a nightmare, but before forming an opinion, think of the Atlantic cable, the telephone and wireless. The future truck will have for its foundation a chassis of standard design and measurement for the different sizes, say, 1,000, 2,000, 4,000, 6,000 and 10,000 pounds capacity. It will have standard springs and fittings. And will provide standard lugs and braces for the motor power. The power plant, I believe, will be operated by alcohol and perhaps it might be well here to give my reasons for such belief. It being a manufactured product, the quantity of which is unlimited, could be regulated to suit the demand. It is safer, cleaner and more agreeable to handle than either gasoline or kerosene and produces a more flexible explosion than either. And I might suggest that if the government would take up this matter of producing alcohol, instead of spending money in useless investigations, we would then get a price much less than that of gasoline at the present time.

The Real Self-Starter

The power plant, as I said, will have standard bosses or projections to fit lugs and braces of the chassis with but three or four bolt holes to fasten it to the same. It will be completely self-contained. The motor will be self-starting, in fact, not the so-called self-starter of today, where we depend on acetylene gas, electricity, compressed air, spring movements or some other form of power. This term, like many more on the automobile, is used for the want of something better. There are no self-starters today. They are auxiliary starters. Our future machine will have auxiliary powers but they will be reduced to two, compressed air and electricity. The acetylene gas generator and tank will have passed away and the only place you will find the water-circulating pump or a carbureter will be in a museum and referred to as Ancient Motor Group. I know there will be a general smile of criticism all along the line when I say that you will find the magneto and that spider-web piece of construction called a radiator in the same group. The motor of the future may be a modification of the Knight, but will not be as expensive in construction and will be much simpler. It will have no timing gears or camshafts.

Now let us see what we have under the hood. A plain symmetrically designed motor (and it won't be a two-cycle either) with no poppet valves or springs, no timing gears or chains, no cam or connecting link shafts, no circulating pump, no magneto, no wiring and no radiator. In addition to this, the motor being self-contained, can be removed for repair or replaced for a new one in less than 1 hour by the driver or an ordinary mechanic.

The Things We Won't Need

Listen, did I hear someone say, this fellow has forgotten about his drive shaft connections, and universal joints? No, but you forget that we are 25 years older and have learned that we don't need any. Not even a clutch, and about that box, filled with chrome nickel steel with more or less grease and trouble mixed in, well you'll probably find that in the same museum with the motor group, but indexed as Ancient Transmission Group. When we have gone this far, we can naturally disregard the gearshifting mechanism, including levers, etc.

Independent Drive for Each Wheel

Now let's get back to the thing that won't drive when one wheel slips, commonly called the differential. We will have to get something here that will give us the results we require and the only way is to drive each wheel independently.

But how? Now we have three methods, bevel or worm gear, chain and internal gear. By the time we have the rest of this car worked out, I guess we will have decided that the internal gear is the thing. And then we shall have a standard size gear bolted to the wheel, with standard size pinions suitable for each chassis of given capacity. Somebody else said I've forgotten the steering gear. No, I haven't. That answers pretty well now, so we will continue to use it.

The Results Will Follow

Now, in going over the above, it will be noticed that I have not attempted to suggest how any of the results are accomplished. But I do wish to say that I have my own ideas and know they are more possible than I would have believed the phonograph was, 30 years ago, or wireless telegraphy, 20 years ago.

Just as soon as the present automobile momentum dies out, someone will have made enough money to spend some of it in giving us what we really want.—WILLIS A. SWAN.

High-Grade, Costly Cars Will Always Have a Field

DESPITE persistent reports of psychological depression in business, the automobile industry continues at a steady pace along the high road of prosperity. To accentuate the contradiction, it is pointed out that conspicuous examples of increased business are found in the field of high-priced cars, possession of which might be regarded as a luxury.

$7,000,000 Sales in 6 Months

During the first 6 months of the calendar year 1914, the Packard company, for example, has established one of the biggest sales records in the annals of that successful concern. During this period, the company's net sales totaled, in round numbers, $7,000,000 and the output of cars was utterly inadequate to supply the demand.

In explanation of these conditions, Alvan Macauley, vice-president and general manager of the Packard company, made the following statement:

"The manufacture and sales of automobiles is perhaps the only specialty business in which every man, woman and child in the United States feels a deep and personal interest. Everyone who hasn't an automobile hopes some day to have one. Those who fortunately own a car are looking forward to the time when they can have a new and better machine.

"The automobile business has been described as the greatest self-advertising business the world has ever known. The entire people are interested, not only in having an automobile, but in having the most up-to-date one their purse will allow. I have been greatly impressed by the eagerness with which the school-boy studies the features of the various cars and promptly forms his own opinion of the various new models as they appear.

"The American tendency is to buy what is most desirable, with the cost as a secondary consideration. Also, there is a noticeable tendency toward keener appreciation of style and luxury in automobiles. Every car manufacturer appreciates the force of this awakening, and is catering to it in so far as the selling price of his product will permit.

Always a Class Putting Quality First

"The field for cars presenting the happy combination of beauty in line, luxurious riding quality, and extraordinary service quality is a distinctive one. There always will be that class which demands the last word in workmanship and design, putting quality first and then seeking the best value to be found in that particular field."

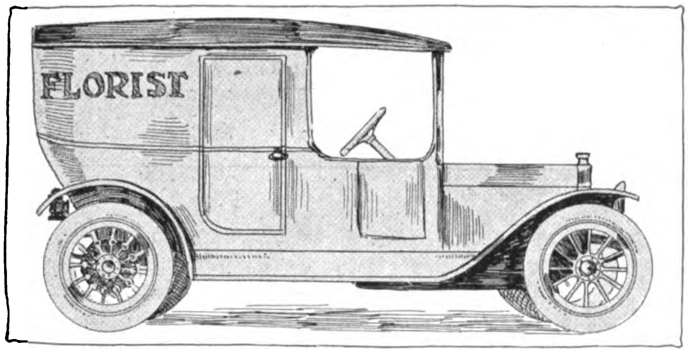


Fig. 1—Limousine converted into delivery wagon

The Rostrum

Suggests Making Old Limousines Into Delivery Wagons

EDITOR THE AUTOMOBILE:—A partial solution of the second hand car problem, is to use the closed cars that have fallen into the discard as delivery wagons. The change is easily and inexpensively made and the result is very pleasing. The delivery wagon-limousine as shown by Fig. 1, is well adapted to many lines of work. It makes an excellent vehicle for florists, dry goods merchants, confectioners and the like.

In making the change, it is merely necessary to remove the rear seat and arrange suitable shelves around the interior. Then, the windows are replaced by mirrors or these spaces are closed up entirely. In either case the cost is not great.

Watertown, N. Y. J. S. S.

Information on Regrinding Cylinders

Editor THE AUTOMOBILE:—1—I am contemplating having the cylinders of my Metz 1913 motor reground and new pistons with Leak-Proof rings fitted. Will you kindly advise me as to how much clearance I should allow between piston and cylinders? Should the pistons be the same size, the whole of their length, or smaller at the top end to allow for greater expansion?

2—Will it be necessary to get oversized rings if Leak-Proof rings are used?

Worcester, Mass. W. C. WHITTUM.

—1—With a motor of this size and speed, the clearance at the lower end should be .006-inch and should taper so that at the upper end the clearance is .012. For a high speed motor of this size the clearance should vary from .009 at the bottom to .015 at the top. In general .00125 inches clearance should be added for each inch of bore.

Whether oversize rings should be used depends on how much larger the cylinders are made. It would be best to determine what size the cylinders are to be and order the rings accordingly.

2—In reboring the cylinders it would be best to follow the S. A. E. standard as you can then probably get pistons to fit the cylinders exactly without any machining. It is recommended that the cylinders be ground .01, .02, .03 or .04 inches large.

How to Adjust Steering Gear

Editor THE AUTOMOBILE:—I have a Staver car, Model 35F in its fourth year:

1—Where are the various adjustments for the steering gear? Will you please designate each one's purpose?

2—Is there any method of preventing screeching of brakes? The leather is very little worn.

3—What is the bore and stroke of this engine?

4—Upon the opening of a petcock in a four-cycle engine for the purpose of determining the number of revolutions, does each report indicate two revolutions?

Minneapolis, Minn. E. F. BORUSKE.

—1—We are unable to give you exact information on this point because we have no photograph or drawing of the steering gear on this particular model and as the Staver is no longer manufactured there is no ready means of obtaining this information.

However, general instructions on the adjustment of the steering mechanism should be sufficient for you to remedy any fault. The steering mechanism is shown in principle in Fig. 2.

Jack up the front wheels, so that all parts of the steering mechanism may be moved freely. Turn the wheel back and forth and note whether there is any play in the gears. The adjustment of these gears varies on different cars but a careful inspection of the steering gear and a little experiment housing should reveal how to take up the play. As a rule the adjustment takes the form of a nut located at the base of the steering column, just at the point where it goes into the housing. By turning this nut the wear is compensated for. There is generally some sort of a locking device for this nut, which must be loosened up before the nut is turned. Be careful not to adjust the gear so tightly that it binds, but just enough to remove all play.

If the gears are so badly worn that the play cannot be fully removed it will be necessary to replace them unless the steering gear is a worm and gear type in which case the steering connections can be loosened and the wheel rotated until the worm meshes with a new segment of the wheel.

Next, examine the steering rod, and if there is any play in the ball joints at the ends this should be removed by adjusting them. By referring to the figure it will be seen that the outer end of each socket consists of a cap threaded into the steering rod and by turning up on this member the play between the ball and the socket is removed.

Note whether the pins or bushings holding the tie-rod are worn and if they are they should be replaced. Also see that the wheel bearings are in adjustment and that the king pins on which the wheels pivot are not worn.

2—Screeching of the brakes can be prevented by putting a few drops of oil on the brake drums. Be careful not to apply too much.

3—This is unobtainable.

4—Yes, because there are four strokes to every explosion in a four-cycle motor and two strokes every revolution.

Gasoline Consumption Is High

Editor THE AUTOMOBILE:—I have an E. M. F. 30 horsepower, 1910 five-passenger car and it has been making about 18 miles per gallon of gasoline. This year it is not making over 8 miles. I have had the cylinders cleaned, new spark plugs put in magneto and carbureter examined. The car runs and does about as well as ever, until after climbing hills or after the engine gets heated. It will begin to miss until after speed gets up to 10 or 12 miles per hour, then it will run all right. After the engine becomes heated the spark lever works very bad.

Parkersburg, W. Va. A. B. Preston.

—We do not believe that the magneto is at fault or that the stiffness of the spark lever is causing the trouble. A method for limbering up the movement of the spark lever was given in the Rostrum for July 30, page 231.

Since your car only misses at speeds below 12 miles per hour and then only when warmed up, it seems likely that the heat causes a slight leakage, either by warping a valve or by expanding a valve stem. Test the compression when the motor is warm and if any cylinder is weak see whether it is not due to lack of clearance between valves and push rods or to a warped valve. These defects would cause enough leakage to make the motor misfire when the throttle is nearly closed but yet not enough to make it miss at wider throttle openings.

Faulty carburetion may also be the cause of the misfiring. Reduce the richness of the mixture when running slowly and see if this makes any difference. It is possible that the reduction in charge weight caused by the heating of the air is sufficient to decrease the ratio of air to gasoline enough to prevent combustion, although when the motor is cold enough air is taken in so that the motor will run all right.

Another possibility is that there is a leak in the intake manifold due to it warping out of shape when heated. Tighten up the bolts holding the manifold and if necessary put in new gaskets.

See that the brakes are not dragging and that the spark advance has not slipped so that you are running with it retarded.

Motor Gets Too Much Oil

Editor The Automobile:—I have an E. M. F. 30, 1910 car. This car, as you know, has an oil reservoir with a gauge. I have been bothered with the engine getting too much oil. I can fill the reservoir full of oil and it will remain in the gauge and tank all right, but as soon as I screw the nut on the oil tank it will go to the crankcase giving the engine too much oil and causing it to smoke.

I have looked everywhere and can find no place where the oil gets air and the oil pump does not leak as long as the nut is left off of the oil tank. If you can give me any advice as to how to remedy the trouble I will be greatly obliged.

Shannon City, Ia. W. A. Hofmann.

—The oiling system, Fig. 3, on this car is so simple that there are very few places that it can cause trouble. It con-

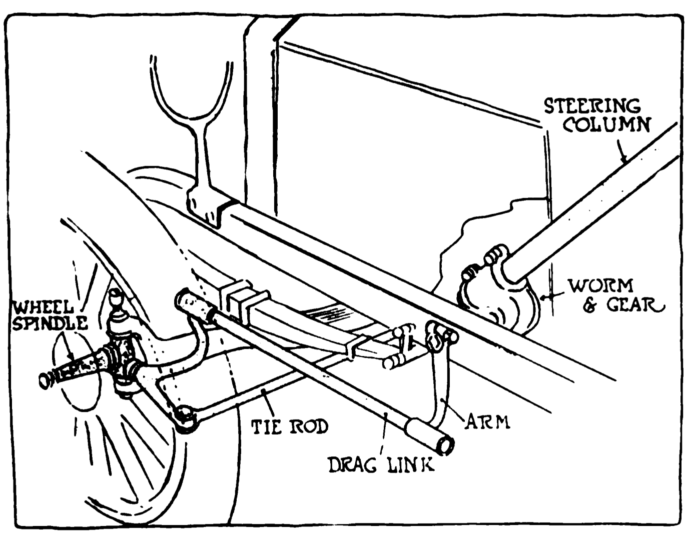

Fig. 2—Sketch of steering gear showing where wear may occur

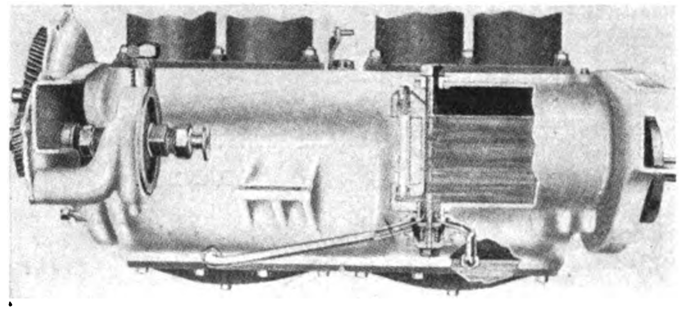

Fig. 3—Vacuum oiling system used on 1910 E. M. F.

sists merely of a reservoir, integral with the crankcase, which has two oil pipes running to the front and rear compartments of the crankcase. A constant level is maintained in the crankcase automatically. When the level drops below the holes air makes its way up into the reservoir and allows oil to flow down until the level is brought up to normal.

An excess of oil can only occur when there is a leakage of air. The leakage may be caused by a worn rubber gasket on the filler cap, a cracked gauge glass or due to small holes in the casting. Inspection should reveal where this trouble is.

Excessive smoking, however, may be the result of using too light an oil, loose pistons or worn rings.

There is no pump in the system.

Marmon 48 Weighs 4880

Editor The Automobile:—What are the weights of the 1915 seven-passenger 48 Marmon with tanks empty and fully equipped?

2—What is the gearing of the Marmon on each of the speeds?

3—What system of lubrication does the new Locomobile use?

4—Which makes the best and most powerful six-cylinder motor, a 4.5 by 5.5 inches or 4.125 by 6 inches?

5—What is the piston displacement of an engine and how may it be found?

Beaver Falls, Pa. A Subscriber.

—1—The weight of the Marmon six 48 is 4,880.

2—The gearbox reductions on the Marmon are: Third—direct; second, 1.63 to 1; first, 3.36 to 1, and reverse, 4.33 to 1. There are four standard rear axle reductions, 3 1-18 to 1; 3.50 to 1; 3.77 to 1, and 4.08 to 1. With the 3.50 reduction the overall ratio between the rotation of the motor and the rear wheels is: Third, 3.50 to 1; second, 5.7 to 1; first, 11.75 to 1; reverse, 15.15 to 1.

3—The Locomobile system is a combination splash and pressure feed, the lubricant being supplied under pressure to the main bearings and the pressure being sufficient to overcome the centrifugal force due to the rotation of the crankshaft. The rest of the motor is lubricated by the splash created by the dipping of the connecting-rods in the troughs. The oil is supplied to the main bearings through a pipe running the length of the motor, a branch outlet going to each bearing, of which there are seven. Oil to the troughs is furnished by another pipe that squirts oil out of individual openings opposite each trough.

4—The 4.5 by 5.5-inch motor will develop more power providing that the design of the two is identical and that the maximum speed of both motors is the same. This is obvious because the 4.5 by 5.5-inch motor has a displacement of 349.9 cubic inches, while the 4.125 by 6-inch motor has a displacement of only 320.7 cubic inches.

5—The piston displacement means the actual volume of air in cubic inches that each piston displaces when moving the full length of the stroke multiplied by the number of

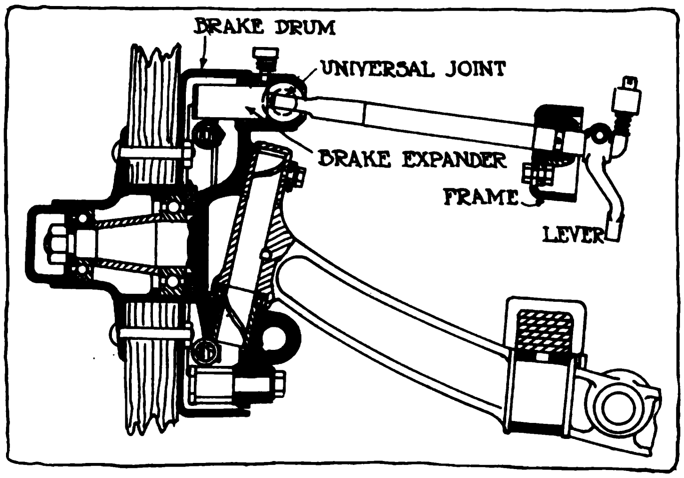

Fig. 4—Argyll front wheel brake construction

cylinders. It is calculated by multiplying the bore by itself, multiplying the result by the stroke and the number of cylinders and then by the constant .7854.

Expressed as a formula, this becomes,

Piston displacement = Bore^2 $\times$ Stroke $\times$ No. of cyls. $\times$ .7854.

The Construction of Front Wheel Brakes

Editor THE AUTOMOBILE:—Please explain by aid of a diagram the construction of the front wheel brake; and if it is possible to install them on a model 19 Buick.

Cincinnati, Ohio. A SUBSCRIBER.

—The construction of front wheel brakes is the same as that of any other brakes except that some special means must be employed for attaching the brake rods so that the wheels may be turned without affecting the brakes.

A typical brake is the Argyll, Fig. 4, in which expanding shoes are used. The movement of the wheel in steering is taken account of by fitting a combination slip and universal joint to the brake rod at the point where it enters the brake drum. The brake rod is also supported in the frame of the car by means of a ball joint so that the flexibility of this member is complete.

It is not advisable to fit front wheel brakes to your car although it is possible to do so. The objections are two in number, the first being the cost, and the second, the fact that the axles and springs are not designed to take this added strain.

Front wheel brakes are less liable to make the car skid when suddenly applied, and when used simultaneously with a rear set, the car can be stopped in about half the time.

Storage Battery Gives Trouble

Editor THE AUTOMOBILE:—1—Could one use 18-candle-power lamps throughout the Chalmers motor and the lights draw from all nine cells? Would not this eliminate this battery trouble that is now present? I have a Chalmers car and about every 3 weeks I have to take the battery to a garage to have it discharged and recharged.

2—What is the weight of the 1913 Pierce-Arrow 38?

3—I have been told that an automobile should have 1 horsepower to every 80 pounds of weight. Is this correct? If not give some formulæ.

4—How many miles per gallon should a 2-38 Packard touring car make in country driving? We only get 7 miles per gallon.

5—Were the electric starters tried out before 1910 and discovered that it required too much power from the motor?

Sudbury, Vt. G. E. S.

—1—You should have your battery and lighting system examined by a competent man as it should not give this trouble if it is in proper condition.

2—4,280 pounds.

3—The proportion of weight to horsepower is a matter of individual taste and also depends upon conditions under which the car is built, however, 80 pounds per horsepower should be satisfactory. If an extremely good hill-climber or a speed car is wanted this ratio might be reduced. On the other hand, the ratio might be exceeded if fuel economy alone were considered.

4—This car should make 13 miles to the gallon according to tests that were conducted by the A. C. A., on Long Island last winter. In these tests the car averaged 13.1 miles per gallon when running at an average speed of 20.8 miles per hour. At a speed of 40.6 miles the mileage dropped to 11. This was with all lamps lighted.

Assuming that you are getting full measure, your car is not as economical as it should be. Readjust the carbureter and see if it does not improve the economy. Drive with the spark as far advanced at all times as is possible without causing the motor to knock. See that the compression is good and that power is not being used by excessive friction at any point.

5—Electric starters were not used to any extent until 1911. They were not tested at some previous time and found that too much power was required as you suggest. At that time the problem was to make a reliable starter and it is doubtful if the question of economy was every raised.

How To Adjust High-Speed Clutch

Editor THE AUTOMOBILE:—1—On a model 40 Overland car, please describe the method of clutch adjustment. The high-speed clutch on this car will drop out occasionally. How can this trouble be overcome?

2—What is the bore and stroke of the engine?

3—The intake manifold on this car is quite long. If the manifold were cut off say 3 or 4 inches this would shorten the gas travel and perhaps avoid manifold condensation. What is your opinion of this proposition?

Haskell, N. J. C. H. BENTON.

—1—The slipping out of the high-speed clutch is probably due to wear in the clutch mechanism or the rod is out of adjustment. If the former is true then the play should be removed, while if the latter is the case the rod should be made the correct length.

2—The bore and stroke are 4 1-4 and 4 1-2 inches, respectively.

3—This would not be advisable for the reason that the difference in the level between the fuel in the tank and the float chamber would be considerably reduced, so much so that the gasoline would not flow on steep hills.

If you are troubled with condensation and are sure that the cause is not poor carbureter adjustment, bad ignition or lack of compression or some other cause, you had better fit a hot-air connection to the carbureter.

List of A. C. Rectifier Makers

Editor THE AUTOMOBILE:—My car carries a 40-ampere-hour storage battery. Will you please tell me through your Rostrum the best kind of apparatus to use in charging it. I have alternating current but no direct current. The A. C. voltage is 110.

Please advise me through the magazine as to the apparatus, its cost, connections, and where I can obtain it.

Steelton, Pa. JOHN B. DOWNS.

—Below is a list of concerns, taken from the Automobile Trade Directory, that make alternating current rectifiers suitable for charging storage batteries. The simpler of these systems can be attached indirectly to any lamp circuit by screwing in a plug. The prices of these devices vary from about $30 up.

American Battery Co., 1132-34 Fulton street, Chicago, Ill.

J. F. Ashbrook, 2639 Emmet street, Chicago, Ill.
Thomas A. Edison, 114 Lakeside avenue, Orange, N. J.
Efficiency Sales Co., 42 Broadway, New York City.
Electric Economy Co., Hyde Park, Mass.

Sirch Electrical & Testing Co., 126 West Third St., Los Angeles, Cal.
Standard Metal Mfg. Co., Newark, N. J.
Wagner Electric & Mfg. Co., 6400 Plymouth Ave., St. Louis, Mo.
Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.
Wilson Supply Co., 1191 Gladys Ave., Cleveland, Ohio.

Why Maxwell Gear Slips Out

Editor THE AUTOMOBILE:—How can I adjust the direct drive of a two-cylinder Maxwell model A. B.? Every time I put the lever on the direct it slips for about a block before it takes hold and drive the car. This transmission is a two-speed planetary.

Larchmont, N. Y. G. L.

—This trouble is probably due to lack of adjustment of the planetary bands. On the outside of the transmission case there are two adjusting screws, one for the low speed band and the other for the reverse. Tighten up on these screws and your trouble should disappear.

It is also possible that there is not enough oil, or it may be that the high speed disk is worn, in which case it must be replaced. Should the trouble be caused by a worn finger, however, it may be eliminated by adjusting it.

American Co. Entered One Race

Editor THE AUTOMOBILE:—1—Did the old American Motors Co. ever enter automobile races? If so, did they win or take prizes in any important races?

2—Could you show me a cross-sectional view of the starting motor and generator used in the Electro system.

3—How many American cars were manufactured when the American Motors Co. went out of business?

San Diego, Cal. MARK JUNGK.

—1—According to the A. A. A. the American Motors Co. entered its own racing car in only one big event and that was at Atlanta, Ga., May 5, 6 and 7, 1910. The reason for the firm not entering any more races after that was because of a protest that its car at that race was not a stock model.

At the Atlanta meet, the car distinguished itself by finishing first in the 50-mile free-for-all, with Herbert Lytle driving. The time was 40:20:02. It came second in the 10-mile free-for-all, its time being 7:43:46. In the 200-mile stock chassis, 451-600 cubic inches race, it came in second; time 3 hours and 5 minutes. The car had a 4-cylinder engine with a 5.75-inch bore and a 5.5-inch stroke, giving a total piston displacement of 571.3 cubic inches. The weight of the car was 2,880 pounds. The car made a mile in 43.19.

2—The Electro system, which is manufactured by the Electro Light & Starter Co., Indianapolis, Ind., is a single unit type in which the starting motor, lighting generator and ignition system are combined. A section through the machine is shown in Fig. 5. The breaker and distributer mechanism are located at the right. The instrument is driven through this end and the commutator is at the opposite end.

The Electro system is a slow speed design in which the armature is driven at crankshaft speed. When operating as a generator it gives maximum current at 350 revolutions per minute, insuring a maximum recharge of the storage battery at about 7 miles per hour.

The gear reduction is automatic and operates only when the engine is being started. It gives a ratio of 25 to 1 and since the instrument when operating as a motor develops 3.5 horsepower, it is capable of turning over any engine at 55 revolutions per minute.

The shock due to the back firing of the motor is taken care of by a friction clutch at A. This cone is fiber faced and the cone ring B has springs C adjusted so as to give the proper friction for turning over the gasoline motor. If the engine backfires, the cone slips and the armature immediately carries it over until the engine starts. This does not affect the timing of the ignition as the distributer is keyed to the driving cone. The advance and retard of spark is accomplished the same as in the ordinary magneto.

3—When the American Motors Co. went out of business there were 3,285 American cars in use, according to the receiver of the company.

Gear Ratios of Racers

Editor THE AUTOMOBILE:—1—What was the gear ratio of the Marmon, Maxwell, Peugeot, Dusenberg, and Delage that competed at Indianapolis, May 30, 1914?

2—What is the horsepower and how many cubic inches of piston displacement has the motor in the Woods Mobilette?

3—What company bought the assets of the U. S. Motors Company when it went into the hands of the receivers?

4—What make of motor does the Saxon car use; rear axle; who designed the car; is not the Ford company putting out this car?

Cooper, N. C. S. B. TEW.

—1—Marmon, 2.33 to 1; Maxwell, 2 to 1; Peugeot, 3 to 1; Duesenberg, 2 to 1; Delage, 3 to 1.

2—The Woods Mobilette is rated at 12 horsepower and has a piston displacement of 69 cubic inches.

3—The purchaser was the Maxwell Motor Co., with W. E. Flanders at its head.

4—A Continental motor is used, and the rear axle is made by the Detroit Metal Products Co. The car was designed by G. W. Dunham. The concern making this car is in no way connected with the Ford company.

No Data on Life of High-Speed Motor

Editor THE AUTOMOBILE:—Please give me all data possible in these columns or refer me to a paper discussing the life and efficiency of high-speed motors (2,500 revolutions per minute or over) compared with the average motor having a maximum speed of 1,700 revolutions per minute.

Elmhurst, L. I. GEORGE W. GAY.

—We know of no paper on this subject.

The Engineering Digest

Two-Wheeled Schilowsky Automobile Balanced with a Gyroscope Weighing 750 Pounds

AN EXPERIMENT MAINLY OF SCIENTIFIC INTEREST

SINCE Brennan of England, Scherl of Germany and Schilowsky of Russia some years ago showed the wonders of monorail transportation, with gyroscopes to steady and balance the vehicles—the two former inventors using two gyroscopes spinning in opposite directions but Schilowsky only one—the question of the application of the gyroscopic principle to automobiles has aroused more or less interest, partly as a matter of scientific curiosity and partly with a view to the sport possibilities which seem to arise the moment a vehicle may be expected to turn corners at full speed without being upset. The theory of gyroscopes has in the meanwhile become better and more widely understood, though still remaining very difficult and obscure in some of its applications to practice, and it has been found necessary to move very slowly in attempting to make use of the principle for common carriers on wheels.

Very recently, however, Schilowsky has had built at the Wolseley Tool and Motor Car company's works a gyroscopically balanced automobile which runs on two wheels and has seats for six, and this car has been shown in operation in London, again bringing the subject to public attention.

The construction of this vehicle serves at least to show that, at the present stage, the mechanical complications and the increase in weight which the addition of a gyroscope equipment render necessary are very serious, apart from the encumbrance which the apparatus represents and the danger of unexpected effects which for some time yet must be associated with its use.

Worked by Heavy Pendulums

The precession or rocking of the gyroscope which tends to take place when it is forced out of its plane of action by movements of the vehicle, and which in turn can be utilized to right the vehicle, is controlled by means of two pendulums, one on each side of the vehicle. The pendulums weigh about 50 kilograms each and do not act on the gyroscope until they have swung to the limit of their lateral motion in the direction away from the vehicle. They are therefore independent of each other, and one of them obviates upsetting to one side and the other to the other side.

Figs. 1 and 2 show the mechanical arrangements of the vehicle in side view and plan, and Figs. 3 and 4 show side view and plan of the mechanical parts by which the gyroscope acts upon the vehicle frame. Fig. 5 shows the same in two transverse sections.

The Wolseley motor develops 25 horsepowers at 1,200 revolutions, and the power is transmitted through a four-speed gearbox to a drive shaft which is set off to one side because the rear wheel is occupying the middle plane. The offset is accomplished by a silent chain from the gearbox. The shaft drives a worm gear on the wheel axle between the wheel and one of the springs. The gears give vehicle speeds of 14, 27, 40 and 55 kilometers per hour.

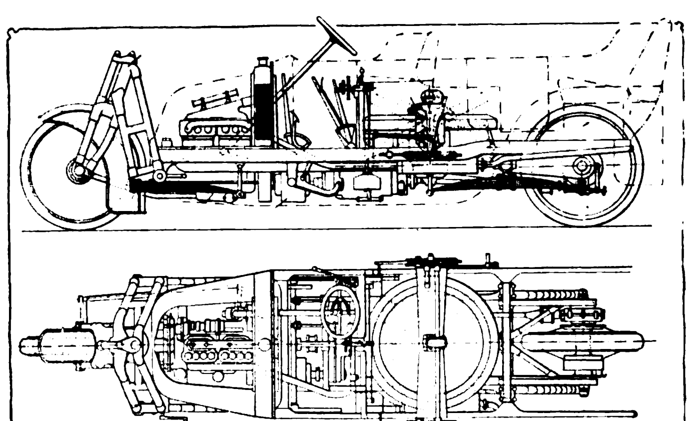
The gyroscope A is actuated electrically and comprises a forged steel disk slightly more than 1 meter in diameter and provided with a rim which weighs 254 kilograms and turns in a horizontal plane at speeds from 1,200 to 1,550 revolutions per minute. The electric motor B is secured to the frame F which carries the vertical axle C of the gyroscope, the armature being keyed directly to the latter. The axle C is guided in the interior of frame F by three roller bearings while heavy ball bearings support the weight of the gyroscope. All the bearings are lubricated from a special oil-circulating system for the gyroscope and its motor. The frame F is a stout casting and is mounted by means of the two stub shafts G in roller bearings secured to the main frame reaches of the vehicle.

The electrical energy used in motor B is furnished by a generator shown in Figs. 1 and 2, which is controlled by means of a coupling-sleeve and a chain taking their movement from the primary gearshaft. The normal speed of this generator is 2,000 revolutions per minute, but it can function at 3,500 revolutions for 15 minutes without heating unduly. If the generator exceeds 3,000 revolutions the gyroscope reaches its maximum speed of 1,550 revolutions and a commutator automatically cuts down the output of the generator so as to prevent further acceleration.

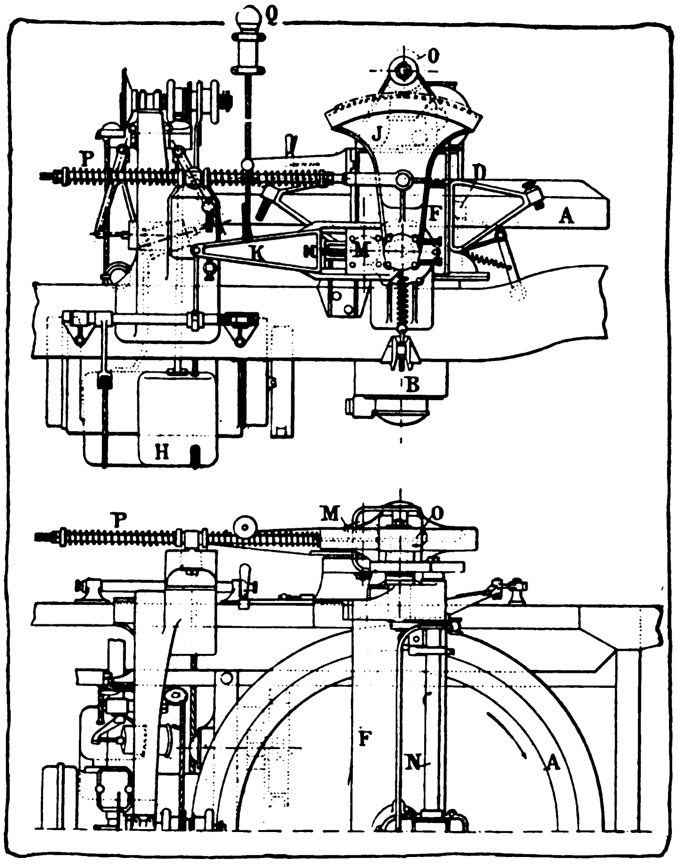
Reducing-Gears Force the Precession

Each of the two pendulums H is connected by a cable and various levers to an arm K at the opposite side of the vehicle, which arm is arranged to be lowered when the corresponding pendulum swings away from the vehicle. It is connected at a right angle with sector J the periphery of which, L, is toothed. At any given position of the shaft M of the arm K every oscillation outwardly of the corresponding pendulum raises the toothed sector J a certain amount.

To co-act with these elements, the movable frame F which supports the gyroscope carries in its upper portion a transverse shaft N to which is transmitted, through a worm, the movement of the shaft C of the gyroscope with a speed reduction of 66 to 1. It may be noted incidentally that shaft N rings a bell at every turn, and this in connection with a simple clockwork indicates at any moment the speed of the gyroscope. Shaft N actuates by suitable gears two spurwheels O which are located at the two sides of the vehicle and turn in opposite directions. Each of these spurwheels can



Figs. 1 and 2—Side and plan views of Schilowsky car, showing general arrangements



Figs. 3 and 4—Side and plan views of gyroscope and mechanism for operating it by automatic action of pendulums

mesh with the corresponding toothed sector L when the latter is raised through the action of the pendulum connected with it. It tends then to displace itself along the sector and exerts a pressure against the upper end of the shaft of the gyroscope, either forwardly or rearwardly—according to which of the two spurwheels is engaged—thereby throwing the precession movement in the direction adapted for re-establishing the equilibrium of the vehicle.

To prevent a violent effect from the sudden engagement of the toothed wheels with the sectors, the latter are braced in their vertical position by the spring struts P. The use of one instead of two gyroscopic disks renders necessary certain precautions when the vehicle is to make a turn in the same direction as that of the rotation of the gyroscope. By means of one of the levers Q, which normally serve to release or immobilize the gyroscopic mechanism, a special pressure is in that case put on the arm K to increase the precession movement in the required direction, the handle of Q being operated directly by the driver.

Takes 10 Minutes to Start

Two safety sprags are let down automatically, to give stable support for the vehicle, if for any reason the speed of the gyroscope becomes too small and allows the oscillating frame of the gyroscope to tip too far forward or backward. These sprags are provided with little rubber wheels and admit of maneuvering with the vehicle when the gyroscope is not running, as in the garage, for example.

For starting, certain precautions must be observed. The vehicle motor is started by hand at a speed of about 500 revolutions per minute which produces a current of 90 volts in the generator. The electric motor is thereafter set going gradually by means of a lever on the dashboard. The acceleration of the gyroscope absorbs 5 horsepowers. After about 5 minutes the velocity of the gyroscope reaches 1,000 revolutions which makes the automatic balancing of the vehicle possible. In order to find at the beginning the properly

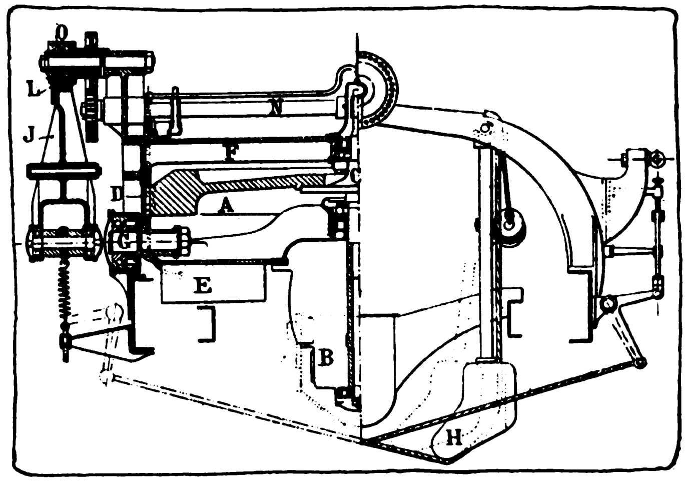


Fig. 5—Transverse sections in two planes through Figs. 3 or 4

balanced position of the vehicle, it is first placed in a position departing about 5 degrees from the vertical and then the two control levers Q are released, thereby releasing also the arms K, so that the gyroscope can begin to act. The toothed sectors J are now alternately engaged with the corresponding toothed wheels under the influence of the pendulums which control them, and the gyroscope thus gradually brings the vehicle into the position which represents unstable equilibrium.

When the gyroscope has attained its maximum speed of 1,550 revolutions, the gasoline motor can be throttled down to still-running, as only from 1 to 1.3 horsepower is then required for maintaining the speed of the apparatus. If the power is cut off completely, the gyroscope will continue to run for 10 to 15 minutes before dropping to the minimum speed at which it ceases to be effective for the balancing of the vehicle.—From *Le Génie Civil*, July 4.

Experienced Driver Formulates a Wish for Improved Motor Control

MR. LEPEUX has driven cars for a number of years and owns one which easily runs at a rate of 80 kilometers per hour, but he considers that the greatest comfort is obtained by keeping up an almost uniform speed of about 50 kilometers per hour, on hills as well as on the level, whenever prudence does not command a slower gait. He has equipped his car with a speed indicator to enable him to know how fast he travels and aims to keep the hand steadily at the figure 50. But at this point he experiences a difficulty. His car needs very little gas to go at 50 kilometers and it is a rather delicate foot action with the accelerator pedal which is required to keep the speed from varying considerably on both sides of the desired mean. A moment of inattention or a light road shock throws the indicator hand to either side. In other words, he has to keep his foot half in the air, in a position which becomes very fatiguing on a long tour. He desires a remedy for this condition.

There is however, the gas lever which does the same as the accelerator, it is objected. Why not use it? Yes, but this lever cannot be operated rapidly. It consists of a screw which must be given several turns to effect the total acceleration that may be wanted. And then, even if the gas lever were handy to use, it would not solve the problem, for the following reasons:

At the start, when the motor is cold, the gas lever is placed at an adjustment which is the best for starting and which the driver soon knows by heart. When the motor has become hot, the driver adjusts the gas lever to the position for still running, so that the motor will not stop when there is occasion for unclutching. This is common and well-known driving practice, mentioned only to make the rest clear.

Now on the road. To drive with the accelerator is fatiguing, as said, and gives an irregular gait. One can then try to drive with the gas lever. To this end, the gas is opened till the indicator shows the desired speed of 50 kilometers per hour on a nice level road. There is a hill ahead, say. A push of the accelerator, and we climb the hill without touching the gas lever, since the latter limits only the backward but not the forward stroke of the accelerator pedal. For the same reason, when the hill is passed, it suffices to release the pedal to make the vehicle resume its normal gait automatically. So far, all would thus be perfect—but: After the level road there follows a descent or a village or an unexpected obstacle demanding immediate checking of the car. Unclutching and braking are instinctive, but with these actions there comes the furious speeding-up of the motor; for the gas lever prevents the accelerator from closing. No less instinctively than before we rapidly push the gas lever back, but in doing so in a hurry we are almost sure to push it beyond the adjustment for still-running, and then the motor stops. Even if it does not stop it is necessary to find again the adjustment corresponding to our desired mean speed of 50 kilometers per hour. And this every time we unclutch!

If others have had the same experience, the modern car would seem to stand in need of a little improvement with regard to its motor control, Mr. Lepeux suggests.

To be sure, automatic governors have been used which never allowed the motor to run wild, but builders will probably not easily conclude to re-adopt this feature despite its advantages. The little problem which seems to present itself may therefore be formulated in the following combination of requirements:

(1) The accelerator should function in the ordinary manner.

(2) The gas lever should limit the backstroke of the accelerator pedal.

(3) When the clutch is withdrawn, the motor should come to its still-running adjustment without need of touching the gas lever. (For greater convenience this adjustment might be secured by a permanent regulation of the carbureter, independently of the gas lever.)

Is it impossible, asks Mr. Lepeux, to contrive this kind of control which would secure for all cars most of the advantages that an automatic governor offers. Such an improvement would not involve great expense. It might consist in applying, concurrently with the accelerator, a retarder device actuated by the brake pedal on the first one-third of its stroke, as has been done on certain vehicles. The control maneuver would then be very simple, as it would be sufficient at every unclutching to push the brake pedal also, to bring the motor to still-running.—From *Omnia*, July 15.

International Trade in Automobiles 123 Million Dollars

OBTAINING his figures from the customs statistics for 1913 in the different countries, a French actuarian, Max Dutray, has compiled the table appended herewith which shows the value of the automobiles sold by one country to another. The figures are of course much smaller than they would be if the sales of each country in its home market were included, still it is noticeable—when a comparison is made with other statistics giving the registration of cars in use and the increase from year to year—that of all the manufacturing countries the United States is probably the only one where the exports do not exceed the home sales. In England the sales to the British public are much larger than the exports only if the very large importations are included, while the importations in the United States have now dwindled to an insignificant figure.

In many instances the customs statistics are incomplete or misleading, as exports are not always listed with reference to the country of ultimate destination, the purchase being credited to the country where trans-shipment takes place. The compiler has corrected this error where it could be traced, as where Belgium was credited with most of the South American purchases from France, because these were shipped from Antwerp, but in many more cases it has not been possible to make this correction. This and other errors find their expression in the large purchases—amounting to 40 per cent. of the total sales—which are found under the heading "Diverse." From intrinsic evidence it is plain that "Diverse" includes many or all of the countries listed as purchasers besides many which are not listed. Assuming that the total of 50 million dollars worth of purchases is evenly divided between listed and unlisted countries, a 20 per cent. factor of inaccuracy in the purchase figures for the different countries listed should therefore be allowed, while the lack of

Exhaust Jacket on New Kerosene Carbureter

Float Chamber and Venturi Tube Surrounded by Exhaust Heat—No Spring Controlled Valves

IN the kerosene carbureter announced by the Senrab Carbureter Co., Sea Cliff, L. I., the vaporization of the fuel is aided by passing part of the exhaust gas into a jacket completely surrounding the float chamber and venturi tube. This heat acts on the thin film of fuel between the wall of the float chamber and the float so that the fuel is adequately heated.

Suitable means for starting with gasoline are provided for by a connection to the side of the carbureter body. Only a few seconds' running on gasoline will be required and the engine can then be allowed to run continuously on kerosene.

An ingenious method has been devised for regulation of the fuel and air supplies, whereby the proportionate quantities of fuel, as well as the main and auxiliary air supplies, may be furnished in proper quantities to suit varying cylinder requirements. In other words, the Senrab carbureter is so arranged that the adjustment of a single moving part effects in proper ratio the fuel supply, the main air supply, and the auxiliary air supply; and under different degrees of running the user can depend upon the admission into the cylinder of a correctly proportioned mixture of fuel and air without the necessity of separately adjusting the several supplies.

Venturi Increases Velocity

The Senrab has taken advantage of the known characteristics of the venturi tube as a passage for the main air supply, because of the increased velocity through a passage having a constricted throat, and because the tube lends itself to the convenient regulation of air by means of a central moving member C, having an annular shoulder directed towards the constricted portion of the tube. This moving member is placed in axial relation to the venturi and carries a tubular fuel supply with radial orifices slightly above the annular shoulder, through which the heated fuel is allowed to pass under the control of a long taper needle and mix with a proportionate amount of air passing through the venturi at high velocity.

In order to provide for atmospheric conditions, the auxiliary valve may be adjusted by revolving the center stem. The needle may also be independently adjusted for varying qualities of fuel.

A method has been provided for control by a lever on top of the carbureter. This lever may be set on the right or left side, or turned in an upward or downward position as desired.

Adjustment Is Simple

The adjustment of the carbureter is simple and permanent. To decrease the quantity of fuel the needle valve A is screwed down after releasing its locknut, while to increase the volume of mixture the collar B is placed higher on its stem. The adjustment of the auxiliary valve is accomplished by revolving the stem after loosening the set screw holding it. After these initial adjustments have been made it is claimed that the carbureter will deliver a proper mixture at all speeds and loads. The throttling function changes the capacity of the carbureter and the mixture does not change owing to the various demands on the motor, it is stated.

If when making these adjustments it is found that the carbureter precipitates moisture on the screen E, it indicates that the velocity is not sufficient for proper vaporization and the stem D should be lowered until the exhaust shows good combustion.

The intake F is for gasoline which is used in starting. After running a few seconds on gasoline sufficient heat is generated in the float-chamber jacket to allow engine to run on kerosene. The kerosene connection is at G, and a portion of the exhaust is by-passed into the inlet H and discharged at J.

On carbureters above the 1-inch size a sight glass is provided at K for inspecting the fuel level. If the fuel is flowing properly the level will be little above the center of the glass.

The prices vary from $15 for the 3-4-inch model to $36 for the 2 1-2-inch.

International Trade in Automobiles

(*Continued from page* 266)

specifications under "Diverse" may also conceal the omission of some important purchasing countries, such as Australia, British India, the Dutch Indies, South Africa and others.

The sales column naturally comes closer to the true figures, the "Diverse" heading in this case representing only 1.6 per cent. of the total sales.

With allowance for the inaccuracies, it is noticed that the principal purchasing countries, among those listed, rank as follows: England $18,000,000; Canada $8,000,000; Russia $7,000,000; Argentine Republic $7,000,000; Germany $4,600,000; Algeria $4,400,000; France $4,000,000; Brazil $3,600,000; Italy $2,400,000.—From *Omnia*, July 4.

Tests for Cars with Two-Cycle Motors

ACCORDING to *The Automobile Engineer* the Royal Automobile Club of Great Britain has issued preliminary regulations for contemplated open-competition tests of two-cycle motors fitted to cars. The tests will include a run of 1,000 miles on the road, with records taken at intervals of the temperature of the cooling-water; tests of car speed on the level without misfires of motor and with records of acceleration on top gear from minimum speed; hill-climbing tests; fuel and oil consumption tests and tests relating to the facility for starting the motor from cold with a given fuel. Noise and vibration will be considered in the awards.

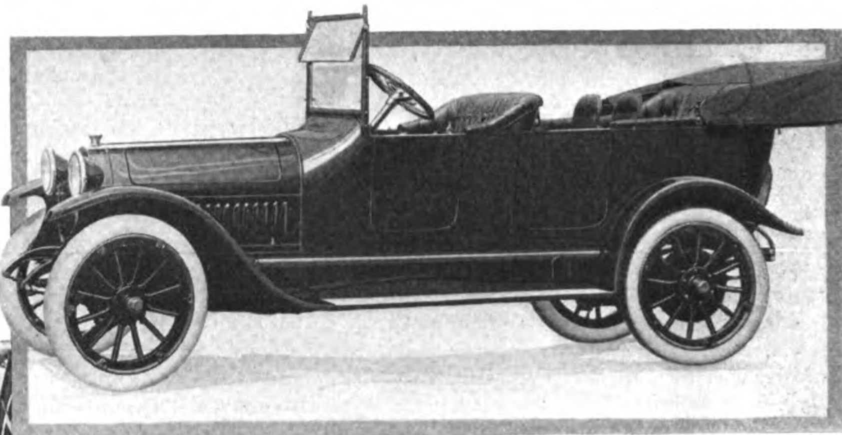
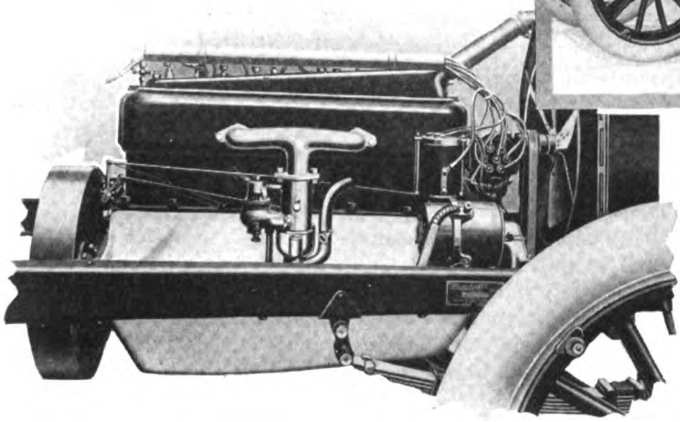
15 Per Cent. More Power in Studebakers

Four Now Sells for $985 —Five Passenger Six, $1,385— Seven Passenger Six, $1,450



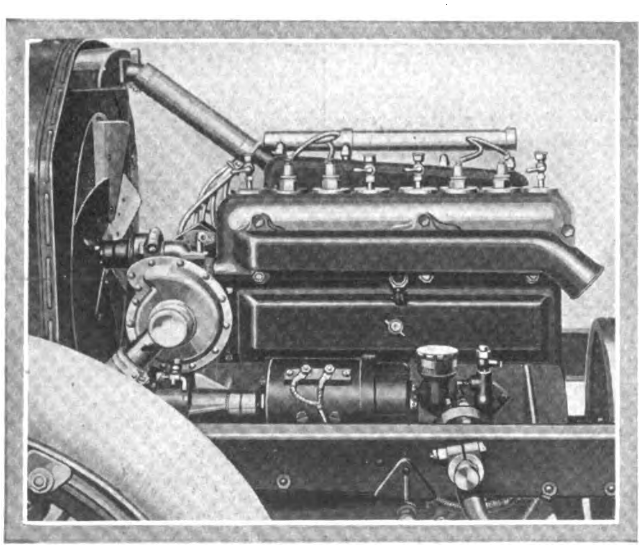


Above—Studebaker seven passenger six touring car for 1915 which with complete equipment sells for $1,450
Left—Intake side of six cylinder motor used in 1915 Studebaker showing Wagner starting motor and Remy distributor as well as Schebler hot jacketed carbureter

STUDEBAKER will continue for 1915 the two chassis, a four and a six, that made up the 1914 line. While the cars are the same as last year in all the elemental features of design, improvements have been made throughout the chassis, body and equipment with the result that the cars are lighter, stronger, roomier and more powerful, although selling for $65 less than last year in the case of the four and $190 less in the six. The price of the four is now $985 and for the six $1,385, with a five-passenger body, and $1,450 with a seven-passenger.

In the motors the maximum power has been increased 15 per cent., according to the Studebaker engineers, by reducing the weights of the reciprocating parts and altering the manifold design. Four ounces has been cut from the piston assembly by using lighter pistons with three rings. The valve sizes remain the same, but the valve ports have been made larger, thereby increasing the efficiency of the motor both as regards intake and exhaust. The splash scoop has been changed in shape and the splash troughs altered to give greater oil economy. While the model R Schebler carbureter is still used it is fitted this year with a waterjacket and also has a means for pre-heating the intake gases from the heat of the exhaust. In the four the carbureter is bolted against the integral cylinder casting without any exterior intake manifold.

The same clutch has been kept for the 1915 car, but the leverage on the operating members on the six has been changed to give an easier throw. The design of the rear axle has been altered and instead of the exterior flange connection with the wheel it now has a tapered-fitting connection with the driving flange and carries a hub cap.



Valve side of four cylinder Studebaker motor showing mounting of electric generator and water pump

Bodies 100 Pounds Lighter

The improvements in the body work and equipment are marked and through them 100 pounds has been cut from the weight of each model. In the body much of the woodwork has been replaced by pressed steel. This has resulted in a roomier design of much less weight. The top now used is a one-man design. The curtains can be put up from the inside of the car and clip to the windshield which is also a new design for 1915.

The instrument board is now a stamping and is so arranged that the instruments project through it but are not supported by it. It is possible by this construction to remove the instrument board and still leave all the instruments in place. The running-board pads have been made of corrugated rolled aluminum which extend the entire length of the running boards. Dome-shaped fenders and improved splash guards add to the appearance of the car.

The interior arrangements permit of more leg room in both the front compartment and the tonneau. There is more clearance between the steering wheel and the cushion, secured by decreasing the steering wheel rake slightly. There is also more clearance between the control levers and the seat. The starting switch for the Wagner system has been moved forward.

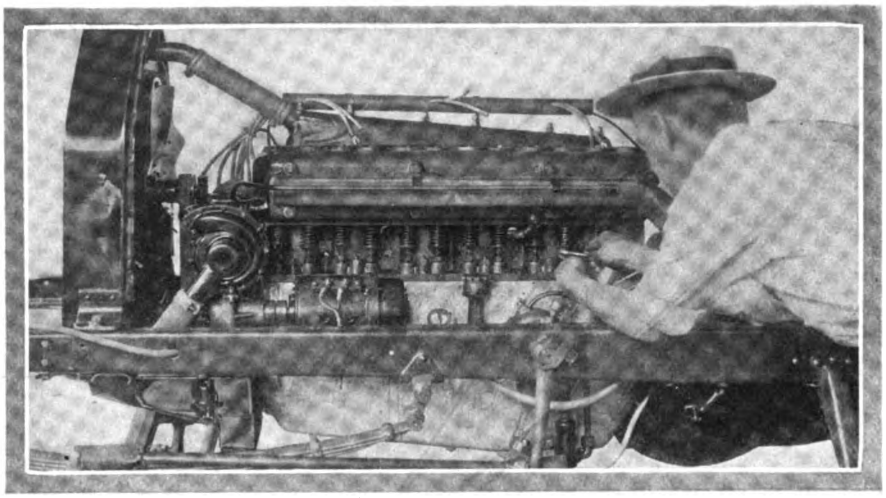
Features of Design Similar

In many details of design the six and four are exactly alike.

Both have their cylinders cast in block, both are L-heads and in bore and stroke, 3.5 by 5, are also similar. This method of duplication of design fits in with the Studebaker policy of standardization for quantity production which is carried throughout both chassis. The pistons, connecting-rods, wristpins and valve assembly are exactly the same in both cars.

The pistons carry but two compression rings this year, as against three in previous designs. An oil-wiper ring is carried at the bottom of the piston in addition. The rings this year are concentric and in manufacture are lapped in the cylinders. The wristpins have bronze bushings.

The 1 13-16-inch valves are carried on the left side of the motor and the adjusting nuts and exterior mechanism are covered by means of light dust-proof plates held in postion by thumb nuts.



Valve side of Studebaker six motor, showing accessibility of valve adjustment

The crankshaft of the four-cylinder motor is carried on three main bearings and that of the six on four. In both instances the front bearings are 1 5-8 inches in diameter and 2 15-16 inches in length, the center 1 11-16 by 2.5 and the rear 1 3-4 by 3 1-2. The bearings are babbitt lined, the babbitt being run in at the factory.

The motor lubrication system is accomplished by a combination force-feed and splash. The supply of oil passing to the motor is visible through a sight feed mounted on the dash. The oil supply is carried in the lower part of the crankcase and from this reservoir the oil is lifted to the sight feed by means of a steel plunger pump. The motor bearings and the cylinders are taken care of by the splash, while the timing gears and connecting-rod bearings are oiled by direct circulation. The splash scoops and troughs are new designs for 1915.

Cooling is accomplished in the six by means of a honeycomb radiator. In the four a vertical tube radiator with an auxiliary tank is used. Both cars use the centrifugal water pump. The cooling problem in the four has been greatly simplified by the use of a larger exhaust pipe than for 1914.

Practically no change has been made in the electrical equipment of the car for this year. Starting, lighting and ignition are still handled by the two-unit Wagner-Studebaker system. One step toward compactness, however, has been accomplished in the motor. This is fully an inch shorter in overall length now than it was in the 1914 line.

The two electrical units are the generator and the cranking motor. The electric motor for starting is connected to the engine crankshaft by means of a roller chain. By means of this chain and a pinion gear reduction the relation of the cranking motor speed to the crankshaft is 20 to 1. The gear reduction is 5 to 1 and the chain multiplies this by four. Owing to decreased internal friction of the motor and the lighter parts the speed of cranking the motor is higher this year than in the previous cars. The actual speed, of course, varies under different motor conditions, but the average amperage draw on starting is 100. The cranking motor is operated by a pedal on the toe board. Connection is broken between the engine and the starting motor as soon as the engine takes up its work by means of a roller clutch. The roller clutch is placed on the crankshaft and therefore when it is out of engagement the entire chain-drive mechanism is silenced as it comes to rest.

The generator which furnishes all the current for lighting and ignition is driven at the ratio of 1.5 crankshaft speed by means of a gear on the camshaft. The generator starts to charge the battery at a car speed of 10 miles per hour and reaches its maximum output at 20 miles per hour.

For ignition the current is taken from the storage battery and, after passing through an induction coil, is led to the Remy distributer on the end of the transverse shaft at the front end of the motor. From this point the leads are taken

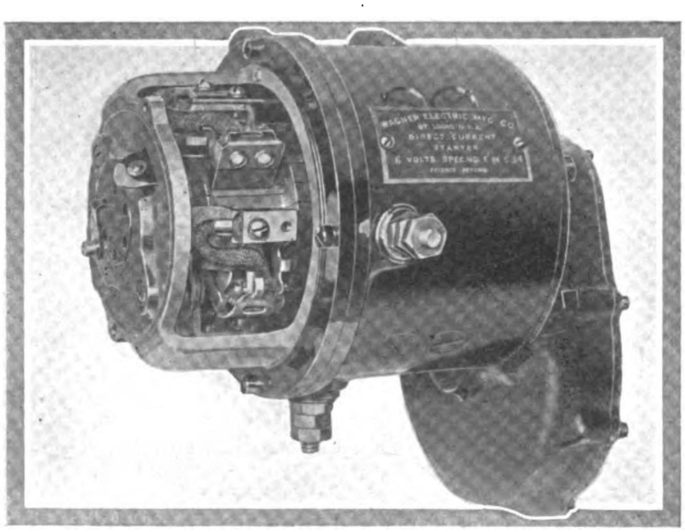
to the spark plugs. Dry cells are furnished for emergency use. The ignition switch is at the driver's right.

Cams in Steering Mechanism

The control mechanism of the spark and throttle has been modified somewhat this year. In place of the ordinary bell crank levers at the ends of the control shafts which project through the bottom of the steering column there are cams which act as guides for L-shaped followers.

The carbureter is turned longitudinally this year instead of transversely, and the result is a neater and more accessible job.

The clutches used on the six and four are direct cones of pressed steel faced with leather, beneath which are placed flat engagement springs. A single clutch spring of heat-treated alloy steel is used. The clutch fork arm on the six is shorter this year than last, while the pedal arm remains the same length, thereby giving an increased leverage on the clutch.



Wagner direct current starter used on 1915 Studebaker

The gearboxes are another point of exact similarity between the two chassis. They are three-speed selective and are the same as have been used in Studebaker cars for three seasons.

The rear axles are floating designs and the same as for 1914 in every particular up to the construction at the wheels. Here the change mentioned has been made and the exterior of the wheels are ornamented by a hub cap. The most material result in the new construction is the elimination of grease leakage from the differential housing to the brakes through the axle tube. The brake diameter has been increased 3 inches and now both brakes are lined with asbestos fabric, whereas on the previous model one set was metal-to-metal.

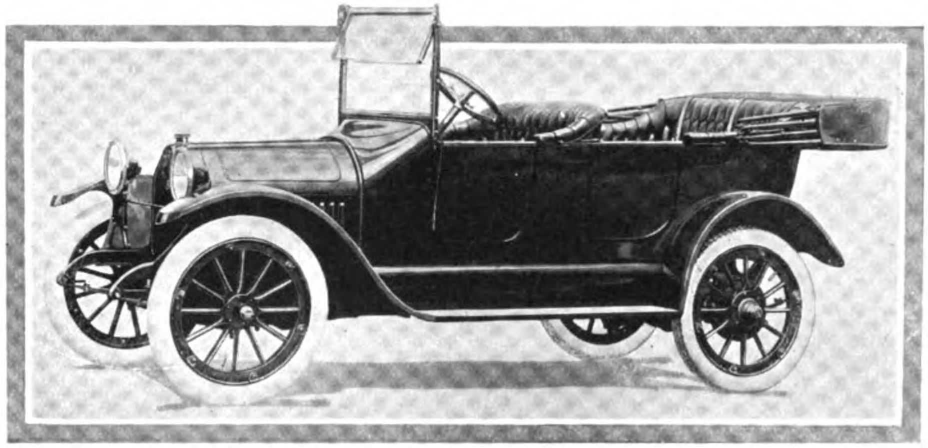
The rear springs are a point of difference between the four and six. On the four, scroll elliptic springs underslung under the rear axle housing are used, while on the six a deep three-quarter elliptic design is employed.

The wheels on both cars are of second-growth hickory artillery design. On the four they are fitted with 33 by 4-inch tires, an oversize for the 32 by 3.5-inch size which was used in the previous model. On the six the 34 by 4-inch size are used. This gives both cars an ample tire size, as the four weighs 2,500 pounds and the six 3,000 fitted with the standard bodies.

On the six there are two bodies fitted, a five and a seven-passenger touring design. On the four there is a five-passenger touring car and a three-passenger roadster. This gives a complete line of four bodies.

Everything is made as tight as possible. This year a strip of anti-squeak fabric is placed between the body and the frame for the sake of silence, and the windshield is lined with rubber for waterproof qualities.

The fenders are crowned and, with the body, undergo twenty-four operations in the paintshop before finishing. The hood, fenders and running gear are black with a narrow white stripe, while the bodies are a dark blue striped with white. The bright parts are heavily nickel-plated. The wheelbase of the four is 108 inches, and of the six 121 inches.



Four-cylinder five-passenger touring car selling for $985 completely equipped

The equipment of the cars is complete. There are no dash lamps, but instead a series-multiple switch on the dash enables the driver to dim the headlights. On the dash there is the Stewart-Warner magnetic speedometer, gasoline filler cap for the undercowl tank, Triumph gasoline gauge, sight feed, etc., while the additional equipment includes an electric horn under the hood, extra rim on rear tire irons and a full set of tools.

Empire Continues One Chassis and Three Bodies—$50 Less

INCREASED production, continuation of the one chassis policy, $50 reduction in price and introduction of a new type in an electrically started and lighted streamline touring car, selling for less than $1,000, are features of the 1915 program of the Empire Automobile Co., Indianapolis, Ind. This gives the company a line of three cars, a roadster being carried with the two touring cars.

The new touring car at $975 has a streamline body and many points of Continental design as well as electric starting and lighting. Seats are set low, allowing seat backs of more than ordinary height. Upholstering throughout is Turkish type of selected leather. All door hinges are concealed, and with the body tapering back from cowl, gives a most pleasing flush side effect, completed by the limousine back. Roll crown fenders add to the general attractive appearance.

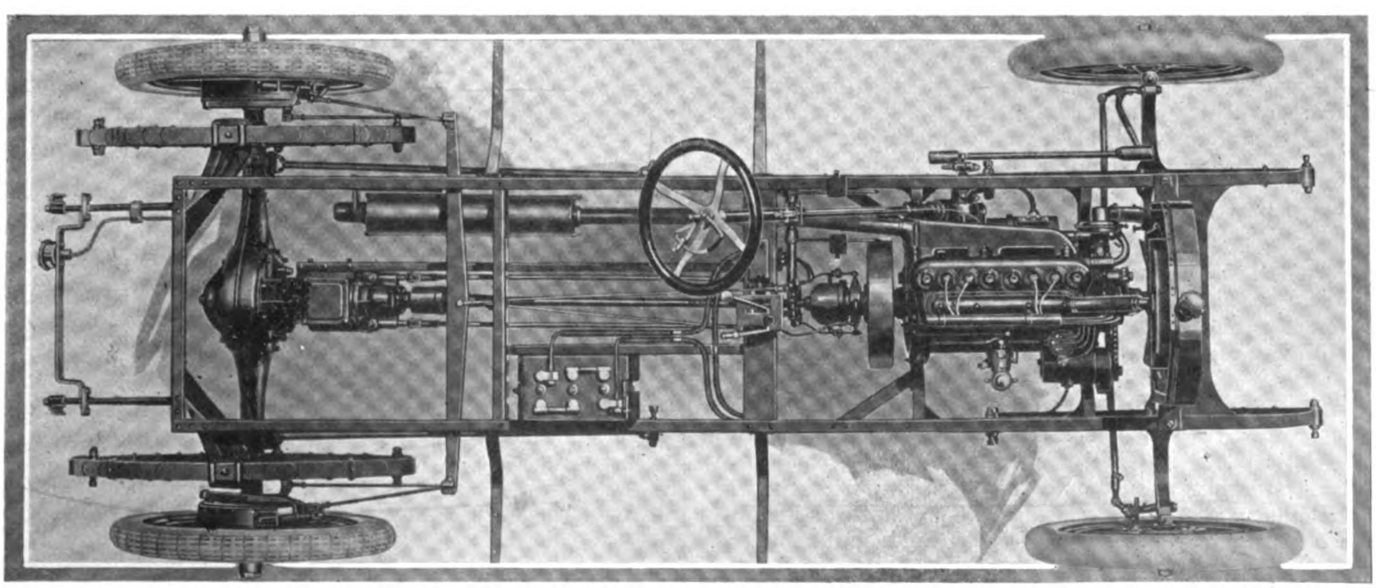
Starter button is of plunger type on dash, while all other instruments, such as speedometers, carbureter adjustment, dash light, ignition switch, battery indicator, light controls, etc., are assembled on an instrument board sheltered by the cowl. Remy one-unit electric system, with starting, generating and ignition of magneto type with spark advance, is fitted. Not only the car itself but also the entire electric equipment, including Willard oversize storage battery, is covered by a 1 year guarantee. Non-skid tires are furnished on rear.

The Empire Standard Model 31 non-electric car, with complete equipment, including mohair top, top boot, curtains, Stewart speedometer, Prest-O-Lite tank, oil side and tail lamps, quick detachable demountable rims, etc., lists at $850. This is in its fourth season, newly improved and refined in many points of detail. Thus, option of either electric or standard car is offered the purchaser. In addition to the touring models the line includes a roadster model furnished either with standard equipment at $875 or with electric starting and lighting at $975.

The chassis has been continued for four seasons without a change in any basic principle of construction. It has a unit power plant with a four-cylinder L-head motor of 3 3-4-inch bore and 4 1-2-inch stroke. Cooling is of the thermo-syphon system with fan, while the lubrication is constant level with force feed by motor pump and three sight feeds on the dash. The motor is fitted with Holley model H carbureter, with dash adjustment. The clutch is a disk type running in oil, while the transmission is selective sliding, with three speeds forward and reverse. Weston-Mott axles are used for both front and rear.

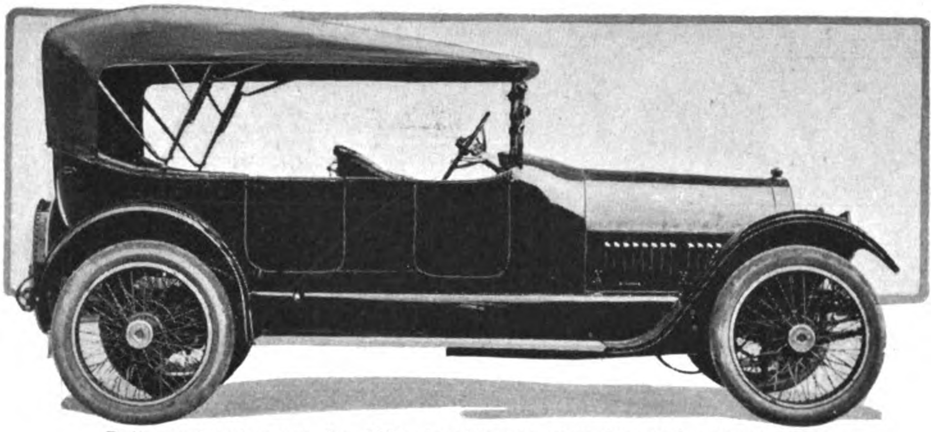
Warner steering gear with 17-inch wheel is also incorporated. Brakes are external contracting and internal expanding, operating on 12-inch drums on each rear wheel.

On these cars, the company will double production over the last season to meet the demands of its dealers.



Plan view of Studebaker four-cylinder chassis, showing mounting of storage battery at right of frame, rear axle gearbox and elliptic rear springs

1915 Pullman Built on Light Six Lines



Pullman touring car for 1915 showing one-man top and new radiator

Minor Refinements on Model 6-48—Wheelbase 134 Inches—Body More Roomy—Lighter and Larger Radiator

THE Pullman Motor Car Co., of York, Pa., will continue the model 6-48 in practically the same form as was introduced at the last New York Show. There have been some refinements, however, the wheelbase having been lengthened 4 inches, making it 134, and this of course has necessitated a larger body and a strengthening of the spring suspension although the car has been lightened throughout. The body has 2 more inches room in the driver's compartment and 6 inches in the tonneau. The seats have been widened and deepened, the rear doors brought back and a leatherette top is used in place of mohair. The dash is now covered with leather and a 12-volt electric system used for starting, lighting and gearshifting. A lighter radiator with larger cooling capacity. The price remains the same at $2,350. Fitted with the Vulcan electric gearshift an additional charge of $150 is made.

The equipment includes a full set of tools, extra wire wheel, motor-driven tire pump, speedometer, and one-man top, held down at the front end by a special attachment on the windshield, thus eliminating straps.

This car is built generally along the light six lines which have come into vogue in the past year. It embodies advanced design straight through from the small six engine to the electric gearshift and streamline type of body.

The motor weighs 600 pounds, including the flywheel and regular equipment. It is of the L-head type and forms a unit power plant with inclosed valve mechanism and three-point suspension. The bore is 3.75 inches and the stroke is 5.25 inches, giving a horsepower rating of 34 according to the S. A. E. formula. On block tests the motor has developed 38 horsepower at approximately 1,500 revolutions per minute.

Cylinders Cast in Threes

The six-cylinders are cast in threes from close grained gray iron which has been aged after the rough boring process to eliminate casting distortions. The cylinder base flange is broad and forms the bases of the guides for the valve lifters. This construction allows for the cover plates which inclose the valves.

The valves are mounted on the right side of the motor and are operated by a single camshaft having the cams integral. The inlet and exhaust valves are interchangeable and have nickel steel heads mounted on carbon steel stems.

The oiling system is a combination force feed and splash with a constant level. The oil is circulated by pumping it through a gear pump with a gallon a minute capacity directly to the main bearings. The overflow from these bearings goes into the splash troughs and also into oil pockets which are designed to feed the lubricant to the timing gears and the silent chain which provides the generator drive.

A multiple disk clutch is used on this car. It is composed of twenty-one disks alternate faces being covered with Raybestos. The tension is provided by two independent clutch springs. This clutch is housed directly with the flywheel and the housing is carried back to include the gearbox, thus providing the unit power plant.

The electrical equipment of the car divides itself into four separate and independent systems for lighting, starting, ignition and gearshifting.

Lighting is taken care of by a Westinghouse six-volt generator connected with a storage battery. The headlights can be dimmed for city driving.

Gearshifting is accomplished by the Vulcan electric device which operates with current taken from the battery. The gearshifting is controlled by a series of buttons located on the end of the steering column which are so arranged that they do not turn with the wheel but are always in the same position.

The control features are all on the left side of the car and the emergency brake lever is mounted to the right of the driver's seat or in the center of the car. The dash equipment is carried on a cowl board and the gasoline tank of 20 gallons capacity is mounted in the cowl.

Detachable Sedan Top New Kissel Feature

Four-Cylinder Touring Car Price Cut to $1,450—Sedan $350 Extra

THE new KisselKar 36 has a lower price than any previous model, and also introduces an innovation in the shape of a detachable sedan top for winter use. The price of the 36 with the touring body only, is $1,450, and the detachable top can be had for $350 additional.

To convert the touring car it is necessary to remove only the windshield, summer top and moulding, and then to screw a metal plate over the door latches. Removal of the detachable top reveals the two-door touring body with individual forward seats. The four-door body can be had for the same price as the two-door, and for $100 more, two disappearing seats and extra tires are included.

The motor is new. It is of an L-head block type cast in the Kissel foundries. Its bore is 4 1-4 inches and its stroke is 5 1-2. It has 2 3-16-inch valves with nickel steel heads. Both valves and lifters are completely housed. The aluminum crankcase is very rigidly constructed with parting line 2 inches below the large diameter crankshaft.

The oil basin, which is of aluminum alloy, has troughs into which connecting-rods dip, and these are filled by means of a positive gear pump which furnishes a uniform stream of lubricating fluid. The oil is drained back into the reservoir in the lower part of the oil basin, through a fine screen before entering the pump for re-distribution.

Carbureter Mounted Directly on Cylinders

Three helical timing gears are used to drive the camshaft, circulating pump and the magneto. The camshaft is of special alloy steel and supported on large white brass bearings. A 16-inch safety blade fan that can under no circumstances cut the radiator is used. The Mercedes honeycomb type of radiator is used. A Stromberg carbureter is used. This is connected directly to the cylinders, doing away with intake pipes.

The power plant is a unit with four speeds, three forward and one reverse. The large leather-faced cone clutch is integral with transmission, and is accessible for adjustment by removing a manhole cover located amidships. Adjustable spring inserts are placed under the leather to insure a smooth and easy engagement. All gears and shafts are of nickel steel, heat-treated.

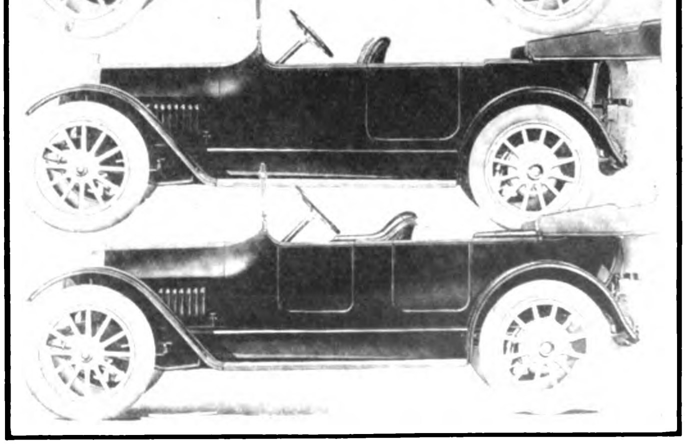
Starting, lighting and ignition are in two units, the Kissel starting system being retained. The Westinghouse system is used for ignition and lighting.

All electric wires on the 36-Four are centralized on a panel attached to the front of the dash. This feature permits the instant location of trouble, and in addition makes it possible to remove the body without cutting a wire.

The wheelbase is 121 inches and the tires are 34 by 4. The frame is of pressed steel with a tapering front to allow short turning. The control levers are at the driver's right in the center of the car. The driver's seat is on the left.

Differential is mounted on taper roller bearings, as are the front and rear wheels. F. & S. annular ball bearings are used in the transmission.

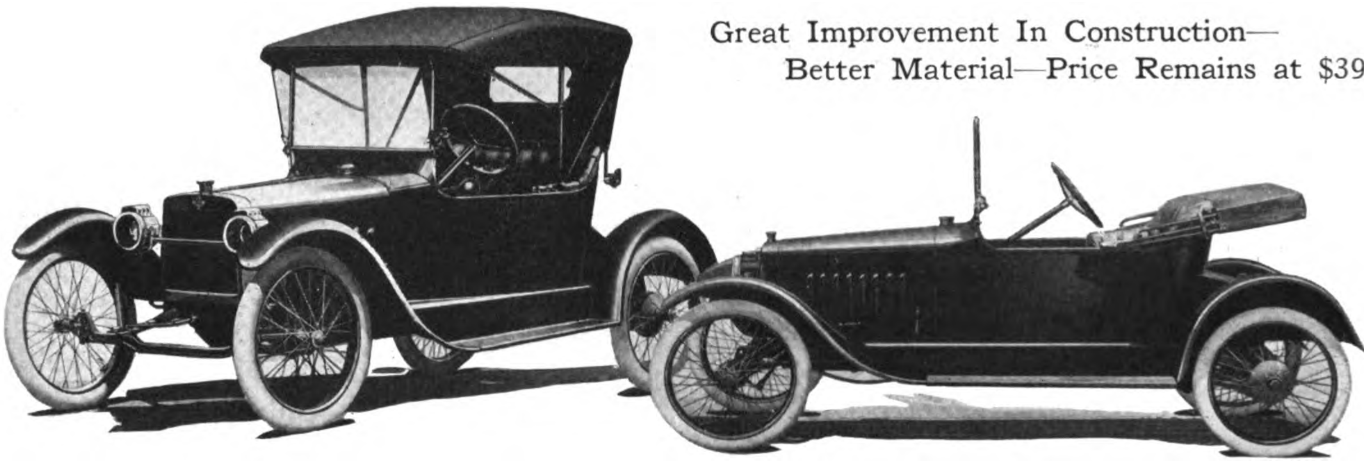
The Stewart vacuum gasoline system has been added to this car. The 18-gallon main tank is in the rear.



Top—Kissel four two-door touring car with detachable sedan top. Middle—Same car with ordinary top. Bottom—Four-door touring

Streamline Body on 1915 Saxons

Great Improvement In Construction—
Better Material—Price Remains at $395



Left—Three-quarter front view of 1915 Saxon with top up and showing new streamline body. Right—Side view of new Saxon. Note running board and tank filler in cowl.

REPLETE with refinements in finish and mechanical construction, the new Saxon for 1915 continues to be sold at $395. This concern, which was organized last year under the name of the Saxon Motor Co., Detroit, Mich., by a number of men connected with the Chalmers Motor Co., has passed a successful year, showing clearly the field of the light car selling at less than $400.

In bringing the Saxon car up to date its external appearance has been altered to a large extent by the fitting of a larger body of streamline form, complete running boards and superior upholstery. In fact, throughout the car, better material will be found than in the previous model. There is now a three-hinged bonnet in place of the one-piece design, rendering it easier to open and making a more rigid job on account of the rod which fits across the top of the bonnet from the radiator to the cowl. The gasoline tank filler cap is now on the cowl, making it unnecessary to remove the bonnet to fill the tank. The starting handle is now polished steel, and the bonnet locks have concealed hinges. In outfitting the body a rubber floor mat is now supplied. The cushions are softer, the seat backs deeper and the springs in the cushions are a tied type, making for greater comfort.

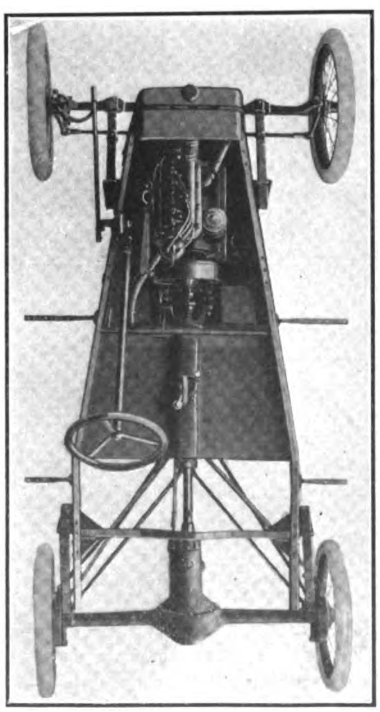
Throughout the entire body-work better finishing has been accomplished. The door locks have been improved and are now a fully concealed design. There is a trim strip on the top of the door and a strap on the right side which prevents it from striking the generator and scratching the door.

Headlights Now in Front

The enamel on the radiator is now baked on, which makes a more durable job. The car has an entirely new color scheme, having a dark blue body with black running gear. The headlights are now in front, in place of on the side, and the leg room in front of the seat has been increased to 18 inches at the bottom and 30 inches at the top of the toe board.

In the detailed mechanical changes the gasoline nozzle on the carbureter is improved, and there is a dash throttle which proves a great convenience as far as ease of starting and guarding against stalling are concerned. The brake straps are now provided with two supporting strings which prevent the straps from rattling against the step brace rod. The battery is now carried in a well, which holds the cells vertically instead of horizontally.

In the new model car the axle has been improved in three details. Two felt washers are now inserted in the ends of the rear axle, which prevent the lubricant from leaking out and covering the braking surface. There is now an oil filler in the differential, which carries the oil directly to the bearings and insures that they are at all times properly lubricated. There is also a through pin for locking the differential pinion carrier, in place of a set screw. Vibration cannot loosen this pin and cause it to fall out. Another feature of the lubrication of the differential and gearbox, which are bolted together in one housing, is the use of an automatic grease level which prevents the grease from collecting in one chamber, thus starving the other of oil.

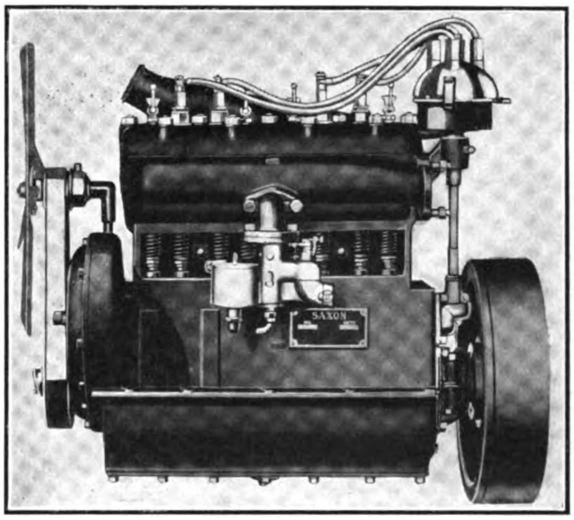


Plan view of Saxon chassis, showing the dust and oil pan, the rear axle gearbox, etc.

Better Material Used Throughout

The steering gear has been improved by the use of better material. The gear pinion shaft is now hardened to make a more lasting job, there is a larger hardened key in the steering gear segment and special carbon steel has been substituted in all of the steering connections in place of the softer material heretofore used. In fact, throughout the entire car there will be found a considerable improvement in the quality of material. In the clutch yoke there was formerly a malleable casting, while now it is a forging with hardened points. On the starting crank there is a collar in place of a pin, and instead of washers under the motor, steel shims are now used. The blades on the fan are now reinforced and there is a jamb nut on the fan support locking screw, which prevents the fan from working loose. The screw on the timer for locking it in place has now a hexagonal head in place of the filister head previously employed. There are now reinforcements at the rear end of the engine pan to prevent sagging or cracking. The handles on the gearshift and brake levers are other improvements.

The power plant of the Saxon is a four-cylinder motor of L-head design with the cylinders cast in a block and carrying the crankcase integral. The bore is 2.625 and the stroke 4 inches. The valves have steel stems and cast-iron heads, and the crankshaft is a drop forging carried on two bronze bearings lined with babbitt. The camshaft is also a drop forging, having a diameter of 1 inch and carrying the cams integrally. It is operated by helical timing gears from the front.



Valve side of Saxon motor for 1915. Note thermo-syphon cooling

The motor is oiled by a vacuum-feed system which provides a constant level in the crankcase by always keeping the oil at the same height as the feed standpipe. In order to eliminate any chance for air leaks in the oil tank there is a new oil tank filling plug which contains a leather washer recessed into it, which acts as an effective packing, making the tank airtight and preventing too rapid flow of the oil.

Atwater Kent Ignition System

Ignition is accomplished by a six dry cell battery system, using the Atwater Kent distributer. Cooling is by thermo-syphon, the radiator being tubular and aided by a belt-driven fan. The carbureter is the latest Mayer, having adjustments for air and gas on the dash. The fuel feed is by gravity from a 6-gallon tank located under the cowl and having its filler cap projecting through the cowl, an improvement over the arrangement in the original car.

The gearset is carried on the rear axle and provides two selective speeds, forward and reverse. It is mounted on Hyatt roller bearings in the case of the main driveshaft, and in the other bearings hardened steel or cast iron is used. One universal is used on the driveshaft, and the torque tube is carried concentric. The torque tube terminates in a forked yoke at the forward end. The steering gear is a bevel gear design with a sector and pinion. The steering post is a steel tube 1.25 inches in diameter, and the wheel has a diameter of 16 inches.

The rear axle is semi-floating and has a pressed-steel housing. The outer end of the driveshaft is carried on Hyatt roller bearings, and the differential is a two-pinion type with plain bearings. The front axle is a single-piece drop forging I-beam section, heat-treated, carrying ball bearings in the hub. The brakes are 8 inches in diameter, lined with Thermoid for service purposes, and the emergency set is steel on steel, 7 11-16 inches in diameter. Both brakes are carried on the rear wheels and both have a 1.25-inch face width. The springs are cantilever design, both front and rear, with the main leaves vanadium steel. Both are 1.5 inches in width, the front 22 inches long and the rear 23 inches long. The wheelbase is 96 inches. The wheels are wire and carry 28 by 3-inch clincher tires. The equipment includes a top, windshield, two acetylene headlights, oil tail light, generator and horn.

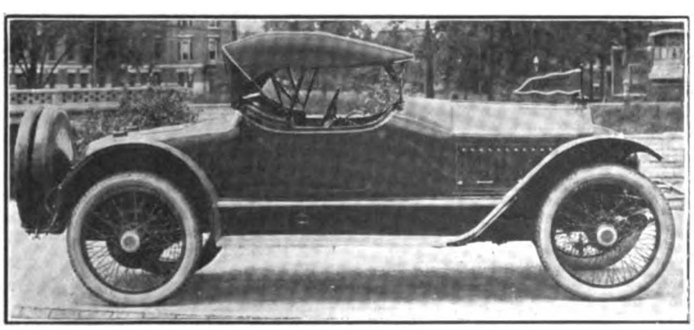
The new battery mounting is a feature of improvement, the placing of the cells in a well rendering a vertical position possible. The cells are held more rigidly, their life is increased and the connections cannot come off.

Makes National Runabout a Sleeping Car

Dr. LeGear, of El Paso, Tex., who owns extensive properties in southwestern Texas, found it inconvenient to travel among them because of the distance and poor train service.

In order that he might travel in comfort he had constructed by the National Motor Vehicle Co. an automobile sleeping and camping car. This roadster has every requisite for camping, being so constructed that a regular pullman bed can be made in the car. Wash basins, cooking arrangements and everything needed by the camper have been provided.

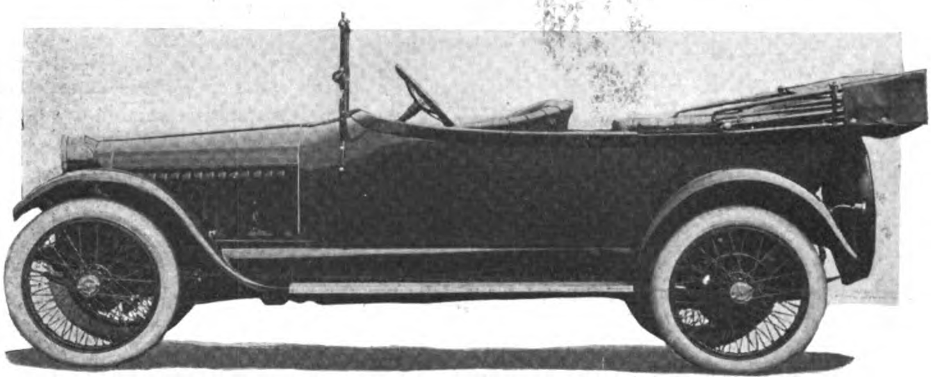
The special body has been constructed on a powerful National car. Special reserve tanks placed under the frame carry a total of 65 gallons of gasoline and 12 gallons of oil. This makes it possible for the National to travel more than 600 miles without taking on any additional fuel supply. The car is finished in light green, with gold trimmings and a large gold star, which is the insignia of Texas.



National Roadster fitted with special sleeping body

View showing the method of converting roadster into sleeping car

Chalmers Master Six Has Boat Body



Chalmers Master six phaeton for 1915. Note new boat-type streamline body

Light Six Also Continued for 1915—Pressure and Gravity Fuel Feed—More Complete Equipment

CHALMERS will continue the two sixes which made up the 1914 line for the coming season. The two cars have been refined at a number of detail points and on the larger chassis a touring body of entirely new design has been fitted. The larger of the two sixes, known as the Master six, was introduced last September, and the light six at the time of the New York show in January. The two present designs are refinements of these two models.

Mechanically the cars are fundamentally the same as in the previous models. The cylinder castings have exactly the same interior dimensions, but the core work has been altered to give better waterjacket space on both models. The gasoline feed system has been altered to a combination pressure and gravity feed. The gasoline is forced by pressure to a small tank on the dash of the car and it then flows by gravity to the carbureter. This arrangement has permitted a slight elevation of the carbureter with better accessibility than last year.

New Rayfield Carbureter

The carbureter itself is different and is now the latest model G Rayfield. Carburetion has also been assisted by increasing the waterjacket space around the intake manifold and also by the better waterjacketing arrangements provided by the new carbureter.

The same type of clutch is used on the new cars, that is a multiple disk with cork inserts, but now the disks alternate bronze and steel, whereas in the previous cars all the disks were steel. The gearbox remains the same, except that second gear on the light six now has a greater reduction. On the light six another change has been made in the fitting of Timken bearings on the front axle. The axles on the Master six have not been changed as to general design, but have been weighted up somewhat to follow the lesson learned on the racing track of making the unsprung weight as much but no more than necessary to have the car hold the road. The speedometer drive on both cars is now the inclosed Empico.

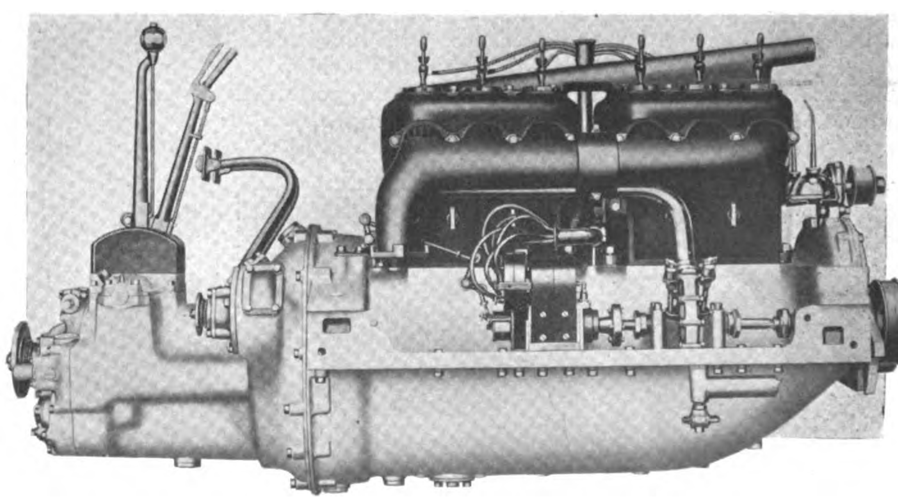
Better equipment will be found on both sixes than on their predecessors. A new design of top which has been worked out in the Chalmers shops is fitted. The storage battery is an improved design having more sealing compound and better separators, which are designed to eliminate buckling of the plates.

A volt-ammeter has been added to the equipment of the dash. The electric switches are also changed in design and a Yale lock is fitted. The appearance of the instrument board has been improved by a rearrangement of the instruments. The tires are larger on the light six. They are now 34 by 4.5 inches, whereas in the preceding cars they were 34 by 4.

Boat Line Body on Master Six

In the body work the cars have been brought up to date in every particular. On the light six there are five bodies listed; these are a five-passenger touring, six-passenger touring, limousine, coupelet and sedan. On the Master six chassis there are two bodies, a seven-passenger touring and a phaeton.

The seven-passenger touring body on the Master six is an innovation for the Chalmers company. It is built on boat lines, carrying the streamline form idea throughout. It has two doors and a passageway between the driver's seat and the seat of the passenger who sits next to him. The driver's seat is adjustable and taken into consideration with the adjustable pedals that are now fitted on all models, a perfect fit can be secured for the driver. There is a ventilating arrangement on the cowl which can be raised and lowered from the driver's seat. This deflects the draught so that it freely circulates about the front compartment of



Exhaust side of Chalmers Master six unit power plant for 1915 the car instead of only reaching the feet of the occupants. This model sells for $2,400. The five-passenger little six is $1,850. This is a raise in price of $125 on the big six and $50 on the light six.

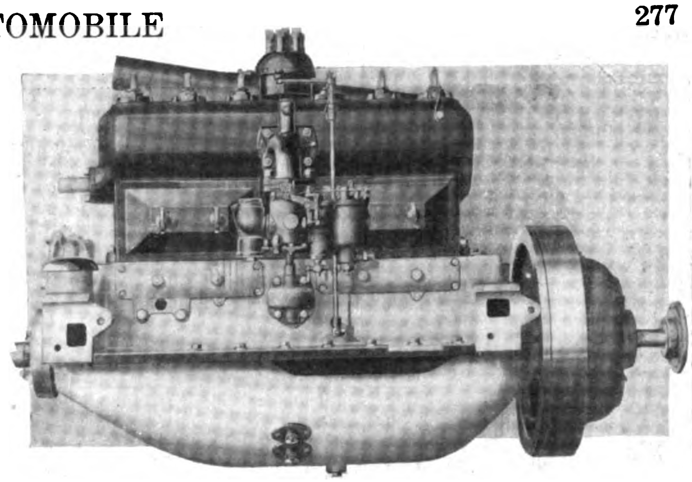
Cars of Similar Design

Both sixes follow along similar lines of design in many particulars. Chalmers made its début into the ranks of the T-head manufacturers last September and now builds nothing but that type. Both chassis have six-cylinder T-head power plants, but the larger car has the cylinders cast in blocks of three, while the smaller one has all the cylinders cast together. The cylinder castings now provide an exceptional amount of cooling space over the heads of the cylinders and around the valves. The intake valves are on the left side and the exhaust on the right.

The cylinder dimensions of the larger six are 4 by 5.5. The smaller six has 3.5 by 5.5-inch cylinders. The S. A. E. ratings of the two models are respectively 38.4 and 29.4. The makers claim dynamometer outputs of 74.3 and 53.4 horsepower for these motors. Last year the Chalmers reciprocating parts were lightened to a large degree and this year the light parts are continued. There is a standing offer in the engineering department of the Chalmers company of a dollar a pound for the reduction of weight anywhere throughout the car. Very close attention has been paid to this feature, but nothing further has been cut in the new cars. The connecting-rods are I-beam drop forgings of open-hearth steel.

Four section-type piston rings are carried. These rings are made up of two parts, the outer ring is complete and inside this there are a number of arc-shaped pieces which form a complete inner ring. Each of the small segments is forced outward by a small leaf spring giving an equal compression all around the cylinder. The crankshafts are drop forgings from .40 carbon steel. They have the crank throws curved so as to bring the center of gravity of the shaft directly on the axis, thereby making for a perfect running balance.

The crankshaft bearings are the same as in the 1914 models, being composed of bronze with babbitt bushings. The bearings are three in number. On the Master six the bearings are 2.125 inches in diameter. The main bearing dimensions for the light six are as follows: Front bearing, 2 3-16 by 2 1-4 inches; center bearing, 2 1-4 by 2 3-8; rear bearing, 2 5-16 by 3 1-2; valve size, 1 15-16 inches.

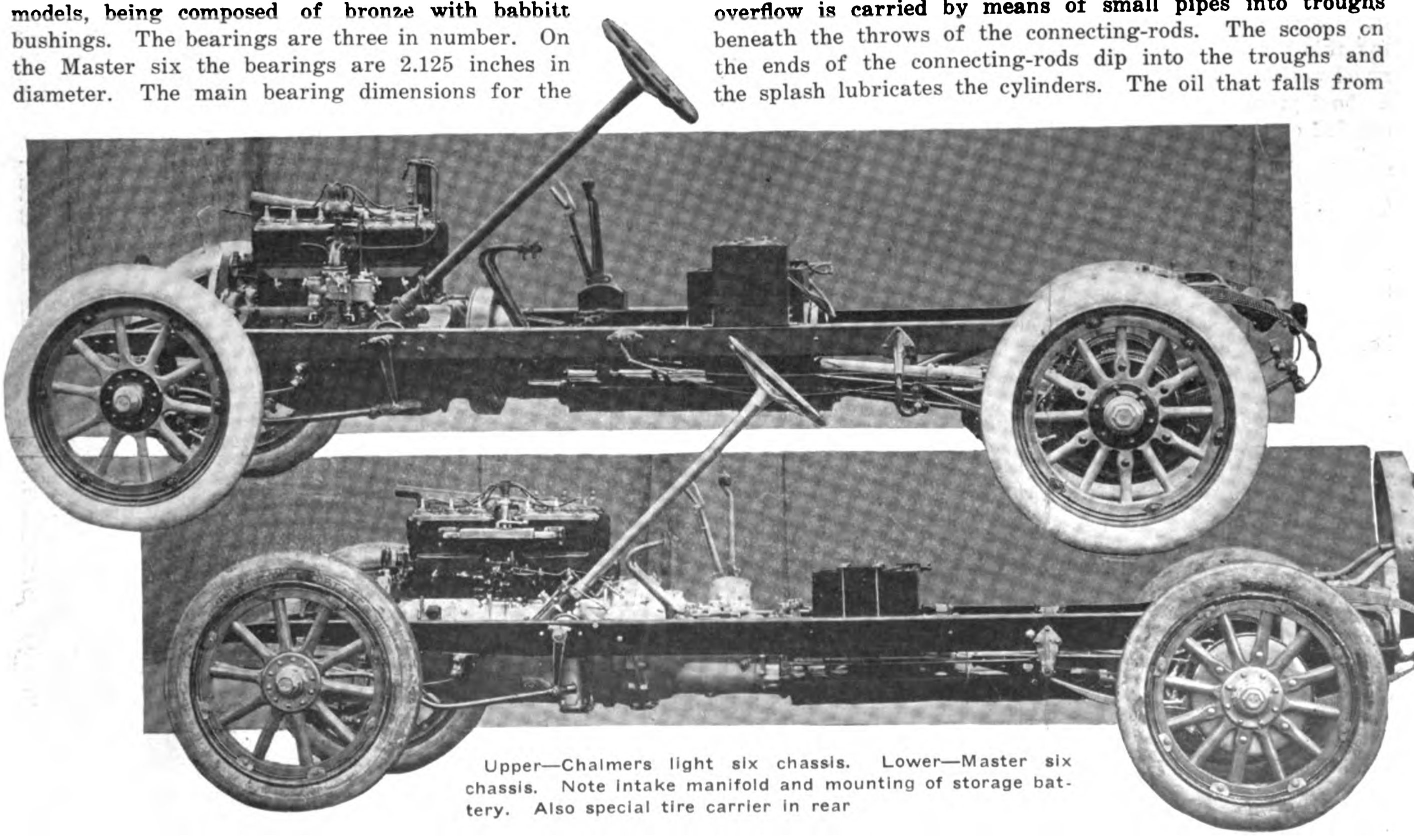


Motor used on 1915 Chalmers light six. Note new carbureter

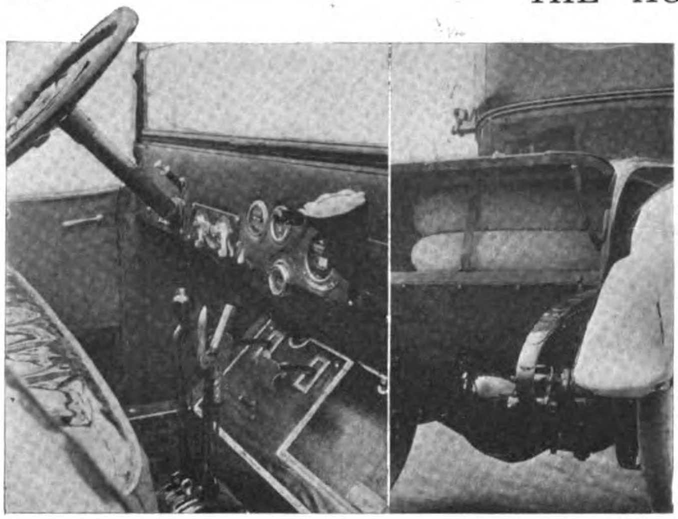
Valves Are of Tungsten Steel

Both the intake and exhaust valves on both models are of tungsten steel. They are driven by separate camshafts, which carry the cams integrally. On the Master six valves are 2.125 inches in diameter and on the light six they are 1 15-16 inches. This gives a very liberal space for the passage of the gases and is one of the features which makes for a high power output on the dynamometer.

The oiling system is essentially the same as that introduced into the Chalmers line in the 1914 design, the only change being in the increase of the size of the oil stream to each of the main bearings from .25 inch to .375 inch. In this oiling system there is a gear pump in the crankcase which takes the oil from the reservoir and forces it through a lead that runs the entire length of the crankcase. From this lead the oil is tapped off at each of the main bearings. The amount of oil that passes to the main bearings is far in excess of what is necessary for their lubrication and the overflow is carried by means of small pipes into troughs beneath the throws of the connecting-rods. The scoops on the ends of the connecting-rods dip into the troughs and the splash lubricates the cylinders. The oil that falls from



Upper—Chalmers light six chassis. Lower—Master six chassis. Note intake manifold and mounting of storage battery. Also special tire carrier in rear



Left—Instrument board and control features of light six Chalmers. Right—Tire compartment in rear

the troughs and the excess from the splash returns to the sump in the bottom of the crankcase, from which point it is again circulated.

An additional oil strainer has been added to the lubrication system. It is mounted on the side of the crankcase and is so arranged that all the oil that is re-circulated passes through it.

Series-Parallel Dimming Switch

Outside of detail features such as a new series-parallel dimming switch the fitting of a volt-ammeter on the dash and the improved battery, the electrical equipment of the cars for the 1915 season is the same as that on the 1914 models. The Chalmers-Entz system is used for starting and lighting on both the Master six and the light six. For ignition there is a Bosch magneto on the larger car and on the smaller the ignition is a battery system with the Atwater Kent distributer.

The Chalmers-Entz motor-generator which met with a great amount of favor last year is continued without change for this season. The motor-generator is still placed in its novel position beneath the right front seat and is driven by a short propeller shaft which extends to the flywheel. It is carried on a bearing at the forward end, and on the front extremity of the shaft there is a small sprocket wheel which is connected by a silent chain to a sprocket on the flywheel. The reduction between these two sprockets is 2.6 to 1.

When acting as a motor the motor-generator is capable of spinning the engine at 100 revolutions per minute under average conditions. When acting as a generator it starts charging the storage battery at a car speed of 8 miles an hour. The generator attains its maximum charging rate at 18 miles an hour. At that time the rate of charge is 15 amperes. The voltage at which the entire system operates is 18. The electrical equipment is largely made in the Chalmers factory. The motor-generator is a product of the Chalmers shops; it is suspended in a very substantial manner by means of a pressed-steel bracket hung from the frame side member. The battery is supported in a similar manner.

New Two-Jet Rayfield Carbureter

The new Rayfield carbureter used on the Chalmers models was described in THE AUTOMOBILE for July 23. It is a two-jet design having three air openings, one of which is fixed and the other two governed by the requirements of the motor. The primary jet supplies all the gasoline while the motor is idling. As soon as it picks up sufficient speed to open the auxiliary air valve a metering pin which is inter-connected with this air valve comes into operation and the secondary jet is opened.

Although the disks have been changed and now alternate bronze and steel, the design of the clutch has not been changed in any other particular. The clutch is operated in oil and has cork inserts. It is a pure multiple disk design.

On the Master six the clutch and gearbox housing is bolted to the rear end of the crankcase as a unit. The gearbox provides four forward speeds. Both the clutch and gearbox can be reached by means of hand-holes which are fitted by cover plates in the housings of the clutch and gearbox. On the light six the multiple disk clutch is used also. The gearbox provides three speeds forward.

The rear axles are floating with a single-piece pressed steel housing. Heat-treated nickel steel is used for the axle shafts and for the driving pinion and large differential bevel gear, 3.5 per cent. nickel steel is also employed. The bearings in the rear axles are Timken rollers.

Equipment a Special Feature

The spring suspension remains as it was; the rear springs are three-quarter elliptics. The improved method of suspension adopted on the larger six when it was first introduced has been continued. Instead of the usual spring hanger the springs are bolted directly to the rear of the frame members. The rear springs are underslung and the design has been worked out to permit of the maximum spring action without bumping. Vanadium steel is used in the main leaves of the springs.

The equipment of the cars has been given careful consideration. The speedometer drive is now the Empico inclosed type, the top is easily handled and makes a tight fit against the vertical windshield. The latter is also changed in design, and on the limousine body there is a double glass that provides an extra shield for rain vision. With this shield the designers claim that the heaviest snow will not interfere with vision. The Master six has 132 inches wheelbase, while the light six has 126 inches. The wheels on the larger car carry 36 by 4.5-inch tires, while on the lighter car they carry 34 by 4-inch tires. Wide doors, with concealed hinges, are a feature of the line of bodies on both. The inclosed cars are particularly luxurious, with attention to the smallest of details, such as cigar lighters, etc. The coupelet, which is a rapidly convertible type, is continued. Tires are carried on the rear of the car in the touring designs and under the rear deck in the roadster.

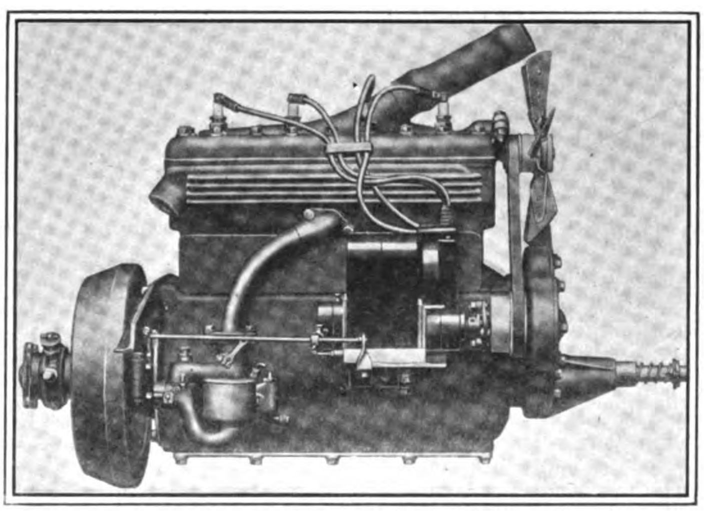
Grant Cuts Price $70 for 1915 —Modified Streamline Body

All Important Features Continued as in 1914—Electric System Fitted at Extra Cost

PRACTICALLY a continuation of the same model as brought out last season, the Grant Motor Co., Findlay, O., has cut the price of this little car from $495 to $425. This price cut is due to increased production and is in line with the statement made last January that when the production passed a given amount the price would be cut.

The Grant car is a typical light car design. It has a four-cylinder power plant with the cylinders and crankcase cast together. The inlet and exhaust passages are also included in the cylinder casting and, together with the inclosed valve action, give a very clean appearance to the exterior of the motor. The Grant company claims an output of 21 horsepower with the 2.75 by 4-inch cylinders. While completely inclosed the motor has been made accessible by the use of a large removable plate at the top of the cylinders, for cleaning cylinders and pistons without removing them. A removable plate is also placed on the base of the motor to permit of adjustment of the main and connecting-rod bearings.



Side elevation of Grant four cylinder motor for 1915

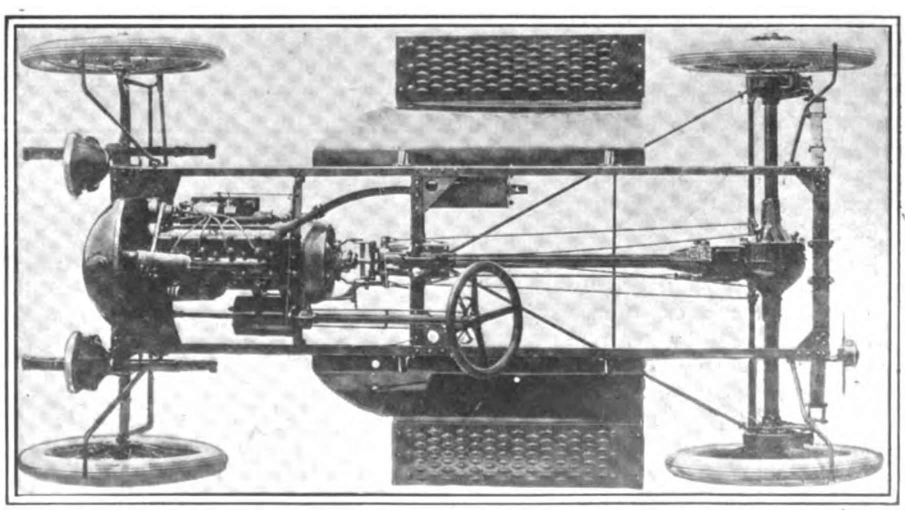
Both the crankshaft and camshaft are drop forgings from alloy steel. The bearings of these shafts are lubricated by constant level splash, oil being fed to the crankcase supply by an automatic drop feed. The carburetor is hung at the rear right end of the motor and is kept low to insure a positive gravity feed. The heat radiated from the crankcase assists in the vaporization of the fuel as it passes up the intake pipe. Ignition is accomplished by single magneto system, the magneto being carried on a shelf at the forward right side of the motor. Cooling is by thermo-syphon and the water pipes are large to permit of a good flow of water through the radiator. under all conditions.

Power is transmitted through a leather-faced cone clutch to a two-speed sliding selective gearset. All the gears and shafts are of alloy steel, hardened and ground and are carried on roller and ball bearings. The drive is by propeller shaft with a ball joint torque tube and the rear axle a three-quarter floating design mounted on roller bearings. The entire load of the car is carried on the axle housing, only the driving stresses being transmitted through the axle shafts. The gear ratio of the rear axle is 4.521.

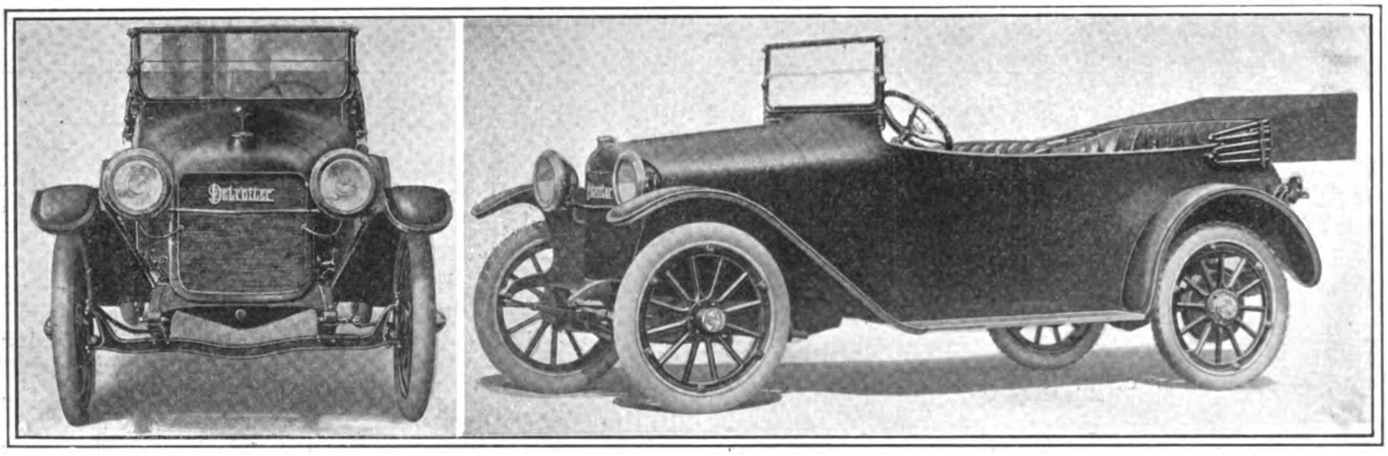
The front axle is a drop forging, having an I-beam section. It is heat-treated and the steering knuckle pins are hardened and ground. The front wheels are carried on ball bearings. Wire wheels are used as standard on the Grant car. They are 28 by 3 and carry Bailey tread tires of this size. Both sets of brakes operate on drums carried by the rear wheels, the foot brake being external contracting and the hand emergency brake internal expanding. The brakes are lined with asbestos babbitt.

Two elliptic front springs are used and one semi-elliptic cross spring on the rear. The road clearance of the car under normal load is 10 inches. Steering is by pinion and gear.

The body fitted to the car is a two-passenger roadster of foredoor design. It has a modified streamline effect, which is accentuated by the round radiator and the cowl dash. The color of the body is black and the chassis and running gear red. The 5-gallon gasoline tank, which the makers claim is sufficient to carry the car for 150 miles, is mounted in the cowl. The weight of the car complete is 1,075 pounds. Standard equipment includes a full set of lights one-piece windshield, top and full set of tools.



Plan view of Grant chassis showing simplicity of design



Left—Front view of 1915 Detroiter, showing streamline design. Right—Side view. Note crowned fenders and boat body lines

Body Improvements Feature Detroiter

Wheelbase Increased from 104 to 112 Inches

WITH a large number of detail chassis refinements and an entirely new body the Detroiter, made by the Briggs-Detroiter Co., Detroit, Mich., will be continued for 1915 fundamentally the same as for 1914. The motor and all the important dimensions of the chassis except the wheelbase remain the same, but the general appearance of the car is greatly altered. The price continues to be $1,050.

The story of the more important changes in the car is told by the fact that the wheelbase has been increased from 104 inches to 112 and the weight still remains the same at less than 2,300 pounds. This has been accomplished by an entirely new design of body, the use of drop forgings in place of castings for the levers, etc., and a light one-man top.

Carbureter Is 4 Inches Higher

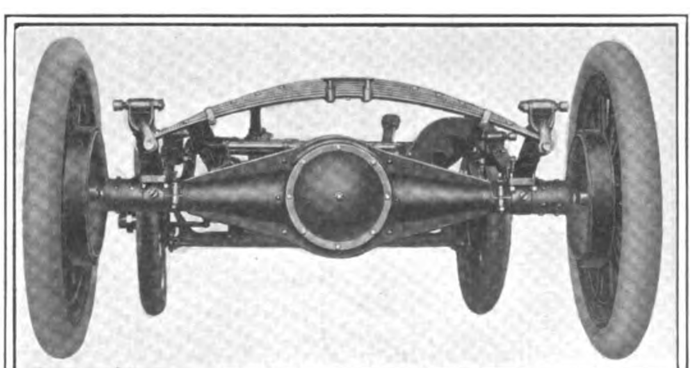
On the motor the carbureter has been raised 4 inches. This is rendered possible by placing the gasoline tank under the cowl. The motor support has been changed and, while it remains a three-point suspension, it now has a full cross member to take the rear supports and a new type of front support which permits the motor to be lifted out directly instead of having to be moved back 2 inches before being removed. The starting motor now bolts directly against the front of the motor whereas last year it was held on a separate shelf. This year the starting and lighting outfit has been changed and while operating at the same voltage and with practically the same connections it is a Westinghouse.

The appearance of the front of the car has been improved by a round radiator which moulds continuously into the body lines. A mud shield has been added to the bottom of the radiator. The rear appearance of the chassis is changed by removing the bracket for the rear platform spring perch and in its place the spring is supported directly by the rear frame cross member. The springs have had an extra leaf added to them. The front now have seven leaves, the rear side, seven and the rear platform eight. Step hangers are supported directly by the body.

Oil Level Warning Light

The brake and clutch pedals are now adjustable for length. The steering gear is a Gemmer ball bearing design and is fully adjustable for wear. In the 1915 car the Detroiter will be fitted with a muffler cutout and accelerator pedals. The instruments, including the bank of electric switches, gasoline gauge, voltmeter, speedometer, instrument light and oil-level warning light are all on an aluminum plate fitted to the cowl board. The oil level warning light is an innovation this year. When the level in the crankcase reservoir drops to a dangerous degree, a metal float makes an electric contact and the red lamp on the dash lights up telling the driver that it is necessary to replenish his supply.

It is in the body work that the most marked change is made. The car has a very distinctive streamline boat-like form. The body is 1.5 inches lower than before and follows the line of the car, starting from the new rounded radiator to the rounded-off stern. The running boards are kept free, the battery box having been removed and underslung from the frame. In the finishing of the body there are now twenty steps as compared to sixteen last year. The doors have been widened to 24 inches. For 1914 they were 16.5. The rear seats are now 45 inches wide in the clear whereas last year they were 41 inches. The body is much more roomy all around with a greater amount of leg space in the front compartment than previously. The windshield is a new attractive rain vision design and fits well with the new one-man American top. The fenders are crowned.



Rear axle construction of 1915 Detroiter. Note platform spring

The four 3.5 by 5-inch cylinders are cast in a block. Motor is an L-head design suspended from the frame at three points. The clutch and gearset housings are integral with the crankcase. The pistons are 4.75 inches in length and are fitted with three eccentric compression rings all fitted above the piston pin. The connecting-rods are I-beams with crankpin bearings which are 1.875 inches square.

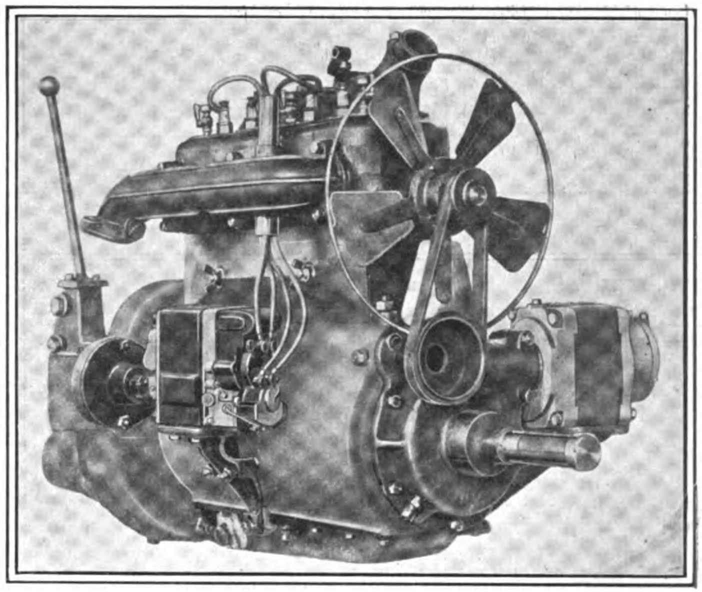
The crankshaft is a drop-forging from high carbon steel and is carried on two annular ball bearings. The camshaft is also a drop forging with the cams integral. These are ground to a limit of 0.001 inch. The bearings for the shaft are 0.937 inch in diameter. The end bearings are 2.5 inches long and the center 1.25 inches. The valves have cast iron heads welded to carbon steel stems. Dust-proof cover plates are fitted over the valve mechanism.

Two per Cent. More Cooling Space

The curved radiator of this season gives about 2 per cent. more cooling space than that used for 1914. The cooling is accomplished by thermo-syphon through large waterjackets, the water intake and outlet pipes having a diameter of 2 inches. Lubrication is accomplished by splash.

Power is transmitted through a twenty-three disk clutch. There are twelve internal and eleven external crucible steel disks which furnish the frictional surface under the pressure of three helical clutch springs. Three forward speeds are provided by the gearbox. The gears used are of high carbon steel and have face widths of 0.75 inch.

The differential and the drive gear assembly form a complete unit and may be removed from the rear axle without disarranging any other parts. A difference in the 1915 model is that the drive pinion is adjustable as well as the large bevel gear of the differential. In the 1914 car only the large bevel gear was adjustable. The differential assembly is carried on two double-row annular ball bearings. The drive ratio at the rear axle is 4 to 1. For 1915 there will be an option offered in this particular. Dealers in hilly territory will be furnished with cars having a gear ratio of 4.33 to 1 if they desire. The axle construction is floating.



Four cylinder 3.5 by 5-inch block Detroit motor

The service brake is 14 inches in diameter and the emergency brake is 10 inches. The wheels are of the artillery type and carry the brake drums. They have twelve 1.5-inch spokes and carry 32 by 3.5-inch tires.

Jeffery Quad Climbs 49 Per Cent. Grade

KENOSHA, WIS., July 29—More than thirty representatives of trade papers gathered at the plant of the Thomas B. Jeffery Co. here today to witness a demonstration of the Jeffery Quad, a four-wheel drive, steer and brake, truck.

The first spectacle was that of running the truck flush against some wooden planks piled 16 inches high and then mounting the planks, running over them and reversing to the original position. All this was accomplished with a load of approximately 3,000 pounds. Besides demonstrating the truck's ability to mount a 16-inch obstruction it demonstrated that either set of brakes could stop the vehicle in almost any position.

Another test was that of climbing a pile of lumber 16 feet high, in which heavy planks were arranged to provide steps respectively 4, 8 and 12 inches in height. The angle of the slope was 49 per cent., or 44.1 degrees.

After the obstacle-mounting demonstration the truck was driven to a very bad piece of land, one which was full of deep holes and bad ruts. This field was preceded by a ditch about 4 feet deep. The truck went through the ditch easily and then through the field, turning around, reversing and doing innumerable stunts suggested by the spectators. After the list of suggestions had been exhausted the quad was driven into the ditch with the frame of the car touching the opposite side. It pulled out by pushing aside some of the dirt.

Another vehicle of similar construction and carrying a load of 3,000 pounds in the form of steel ingots, showed what could be done with a trailer similarly loaded. The trailer was taken in and out of the ditch, through the field, and in short followed the wheels of the tractor around the same torn-up land as did the other car. A braking test was next staged. The car came around the testing track which is used by the company for testing its chassis at approximately 15 miles per hour and the brakes suddenly set. The car stopped within 8 feet. The Jeffery Quad was then backed against a wall of one of the buildings. The motor was started and the gears thrown into mesh, but the wheels could do no more than spin around.

The Jeffery Quad which made this remarkable showing is of the four-wheel-drive type, with all wheels braking, steering and driving alike. A small high-speed motor, 3 3-4 by 5 1-4 inches, the same engine as is used in the four-cylinder Jeffery passenger car, furnishes the motive power. This motor is mounted under a hood in front of the driver but centered in the floorboards. An exceptionally large radiator is used, which makes the motor bonnet invisible from the front. This engine drives by shaft to a large gearbox from which two shafts extend, one operating the front driveshaft and the other the rear. The driveshafts are parallel to the dead axles. The drive is by internal spur gearing. All four wheels are exactly alike.

Jeffery Quad climbing 49 per cent. grade in factory test

SPECIAL NOTICE—Mr. W. I. Ralph, vice-president of The Class Journal Co., assisted by Mr. Henry Knott, will have temporary charge of the Detroit territory in place of Mr. L. G. Vogel, whose resignation has been accepted to take effect August 6, 1914.

New Merchandizing Methods

THE announcement in this issue of THE AUTOMOBILE by two different concerns that a refund of a substantial portion of the purchase price would be made providing more than a certain number of cars were sold during the coming year, is one of the most interesting statements made for a long time. It should do a great deal to further popularize the automobile, and will bring it within the reach of more people. Further, it will undoubtedly inspire greater confidence in these concerns, as it is conclusive evidence that they are honestly trying to retail their products at the lowest price.

One of these concerns is a manufacturer and promises to make a refund of 10 to 15 per cent., while the other is a dealer and states that a rebate of $50 per car will be given.

From the viewpoint of the manufacturer this move marks a great advance, and solves in a degree the question of price reduction. No risk is taken on the manufacturer's part. In either case his profit is assured, but if the stipulated production figure is reached the purchasers get the benefit of reduced cost of manufacture.

The dealer's case is similar, his overhead charges are distributed over a greater number of cars and hence the conditional reduction.

This new method of merchandizing should prove a success, and its progress will be watched with interest, because the principle involved is applicable to many other lines of business and its extension might make an appreciable reduction in the cost of many articles.

A Time for Study

WAR, the greatest evil that can befall commerce of every kind, has already had a perceptible effect upon our export trade. Many of our largest and most active companies have received cablegrams from Europe to the effect that it is no longer safe to ship cars, parts and accessories to Great Britain, our leading customer for these goods, or to the other European countries.

Just when the majority of American manufacturers were beginning to pay serious attention to the great possibilities of foreign markets and in return the foreign markets were beginning to look to American manufacturers as never before in the history of the automobile industry, the precipitation of hostilities gives this growing trade a severe setback. And one of the most unfortunate aspects of the entire situation is that it is not only our trade with European countries which is affected but also that with countries in the East, in South America and other quarters, owing to the fact that the merchant marine of the world is largely owned and controlled by Great Britain and therefore of little service in carrying our exports abroad. Such cars, parts and accessories as we will be able to ship must be carried by either American vessels or those of other countries which are not involved in the European war.

Thus a study of the situation shows that, temporarily at least, our export trade will be terribly handicapped, but the makers must not allow this to make them despair of further developing their market in foreign countries. True, they must concentrate for the present on the domestic market which, owing to the splendid crop conditions reported throughout the ocuntry, is apparently ready to take more cars than ever before. But, while doing this, they must also keep closely in touch with their foreign interests if possible and utilize the interval in active foreign trade by more closely studying its requirements and preparing for an aggressive campaign upon the return to normal conditions.

This is also an opportunity for our makers to secure the business in South America and the Far East, which European makers formerly controlled.

This is a time for study, not only of the foreign market that was, but of the foreign market that is to be upon the close of the war. Conditions will probably vary and requirements may change. The companies which take these things into consideration and study and plan accordingly will be those whose export business will profit in the end.

War Shatters Motor Exports Boom

Detroit Has Two Hopes: That Britain Will Not Be Drawn into the European Battle Royal and That United States Government Will Establish a Merchant Marine to Facilitate Shipments to Neutral Ports

DETROIT, MICH., August 3—The general European war will have a far-reaching effect upon the whole American automobile export business, and no one can at the present time estimate how many millions of dollars will be lost by the Detroit manufacturers, as the local motor-car makers have been providing about 50 per cent. of all the cars exported by this country.

If the war is confined to the continent of Europe and the United Kingdom is not drawn in, the loss will not be so far-reaching, but inasmuch as over 50 per cent. of the exported cars to Europe have been shipped to Great Britain alone, it can be readily seen how great the difference is with England also fighting.

An idea of how the automobile business will be affected can be better gained by showing the United States Government statistics for the 11 months of the fiscal year ending in May. Up to that time a total of 27,018 automobiles had been exported to all countries of the world by the American automobile manufacturers, and the value of these cars was $24,583,435. Out of these 27,018 automobiles 12,521, or 46.3 per cent., having a total value of $9,733,600, or about 40 per cent. of the total value of all cars exported, were shipped to Europe.

From the information gathered at the Detroit automobile plants it is safe to say that fully 65 per cent. of the automobiles exported by this country are coming from the local manufacturers and one or two other Michigan concerns, and the general opinion among these manufacturers is that the war is a hard blow to their foreign business, not only with Europe but with all other countries.

Effect of War Doubtful

"Nobody can predict what the effect of the war will be upon the American export trade in motor cars and parts," said the general manager of one of the big concerns doing a large foreign business. "If the war would be confined to one or two countries, and not include England, the situation would be less gloomy, but with all the big powers engaged in war it will be a long time before there will be any chance of resuming anything like natural business relations with Europe. Even if we had the chance of sending cars over we would not take the risks as the general financial conditions will become such that the people won't have any money to spare except for their immediate requirements and these will not include automobiles. The best thing for the American manufacturers to do now is to develop his home trade and that with Canada and then prepare to supply Europe when Europe will be ready to buy."

One of the officials of the Hupp Motor Car Co., which has one of the biggest foreign automobile businesses in the country said: "There is no question that if the war lasts any length of time the American automobile export trade all over the world will be greatly affected. For a short time South America, Australia and Asia may not be strongly affected but there will be a lack of shipping facilities and the financial conditions will also render the export business much more difficult to handle."

"There will be such a big falling off in the American automobile export business that it will make one think of the time when the first export shipments of American cars were made," said the foreign manager of one of the Detroit manufacturers. "Canada can hardly be called a foreign country and thus the number of cars to be shipped will be very small. If we had a merchant marine it would be different, but now we ship practically 85 per cent. of that which goes to foreign countries on ships flying a foreign flag and about 70 per cent. is divided among British and German ships."

"Most discouraging is this war," said the foreign sales manager of another big local plant. "The American automobile business in Europe had just started to become really important and we had an exceedingly good year abroad with splendid prospects. Now this is only a dream and who can predict when the time will come when the American trade will again be as prosperous over there as it has been during the last 18 months? If Great Britain could have been kept out of the muddle it would be different, but now it is a situation which could not be worse, as far as European trade is concerned, as Great Britain has been the biggest customer this country has had. No doubt can exist that within a comparatively short period the business in motor cars with the rest of the world will also be reduced so much that it will barely amount to anything. The reason will be the lack of transportation facilities, as we have no ships, and the inability of foreign bankers to make settlements."

An official of the Studebaker Corp. said: "The British people control practically all the shipping facilities of the world and with Great Britain drawn into the war the whole shipping system of the world will be reduced to such a small scale that there will be no way of taking care of export trade. But even if we could effect shipments to Europe now we would not take the chances as the risk is much greater that the cars would not reach their destination and be unloaded at the port of arrival and taken to some warehouse or some other place at our risk."

"Last week we had orders for cars from South Africa and from England," said one of the officers of the King Motor Car Co., "but the orders were subject to the shipments being made per American steamers. As we have such a small number of ships flying our flag the situation is a very difficult one. This should be a warning to our government and ought to open the eyes of every American and make him realize what it means when a great, or rather, the greatest of all nations, has no merchant marine of its own.

"One of the principal reasons why the war will greatly affect the whole American automobile export trade," said the spokesman of one local manufacturing concern, "is the fact that in many countries all settlements are made through drafts negotiated through London. This is specially the case with some of the South American countries, Japan and Australia. Many bankers do practically all of their business with London banking houses and with Great Britain at war you can readily see what chances these foreign banks have to transact business with London. Of course there are concerns which have no recourse to London and do their business through New York bankers, but the number is not large and they would be hampered in other ways so that the export business might be considered non-existent for some time."

English Engineers Conclude Belgian Visit

ANTWERP, BELGIUM, July 30—The visit of the Institution of Automobile Engineers to Belgium, which came to a conclusion last week, was probably the most successful of any of the visits hitherto held by the institution. The Minerva Motor Co.'s factory was visited in this city. One of the most striking things noticed in these works was the use which is still made of machinery which might by some be considered somewhat out of date. But any disadvantage there might be, it would appear, is to be fully compensated for by the very low rate of wages which is paid to machinists in Belgium, about $.10 an hour. Other large plants were also visited.

Rates for Charging Electrics Less

NEW YORK CITY, July 30—The reductions in the rates charged for electricity by the New York Edison Co. during the past three years may be taken as conclusive testimony of the increasing use of electric vehicles. Prior to July 1, 1911, the rate averaged approximately 3.5 cents per K.W. hour. Between July 1, 1911, and May 1, 1914, the rate was reduced to less than 3.25 cents, and on May 1, 1914, the minimum rate, based upon the consumption of 50,000 K.W. hours monthly, was lowered to 2 cents a K.W. hour. The new rates which are now in force are as follows, these being dependent upon a minimum monthly bill of $25:

The first 2,500 kilowatt hours monthly at 5 cents; next 2,500 kilowatt hours monthly at 4 cents; next 5,000 kilowatt hours monthly at 3 cents; next 20,000 kilowatt hours monthly at 2½ cents; next 20,000 kilowatt hours monthly at 2¼ cents; excess over 50,000 kilowatt hours monthly at 2 cents.

Lower Ford Prices $60 to $120 a Car

Revised Profit-Sharing Plan Includes Fixed $60 Reduction and Other Tentative Benefits

DETROIT, MICH., Aug. 1—Prices of Ford cars have been reduced. A plan announced for the coming year will include a sharing of the company's profits by customers. This is said to complete the triangular profit-sharing plan which the company had in mind when the employees were given a portion of the earnings of the company.

Each car has been reduced $60 and is sold with the understanding that if 300,000 cars are disposed of between August 1, 1914, and August 1, 1915, each person who buys a car between those dates will receive an additional discount of from $40 to $60, making a total reduction of $100 to $120 on each car.

Thus the touring car, which has been sold for $550, will sell for $490, and under the conditional plan the price will amount to $450 or $430; the roadster is cut from $500 to $440, with a possible added $40 or $60 discount, and the town car drops from $750 to $690, with the possible added reduction.

The 300,000-car output represents, it is stated, a condition of maximum efficiency in the Ford plants and will make the profit sharing possible. The distribution of about $18,000,000 is entailed.

The reductions in the Ford prices concern only the American Ford company, and the output of 300,000 cars is to be produced by the Detroit plant.

N. Y. Overland Agent Has Profit-Sharing Plan

NEW YORK CITY, Aug. 4—The C. T. Silver Motor Co. has inaugurated a conditional price reduction plan in connection with its 1915 sale of Overlands. If the sales by August 1, 1915, total 2,500 cars, $50 will be rebated to each buyer and a further rebate will be made if the sales reach 3,000. This will entail a disbursement of about $125,000. Silver believes his sales for the year will exceed 3,000.

Government Has Devised Glare Antidote

WASHINGTON, D. C., Aug. 1—The problem of eliminating the glare of motor car headlights, against which municipal ordinances and police regulations in many cities have been placed in force, is to be taken up by the federal government. In compliance with a request of the Automobile Club of America the bureau of standards, department of commerce, has devised a method of accomplishing this result and this method now is being tested. Director S. W. Stratton, of the bureau, has recommended that a patent dedicated to the public be taken on this method.

Director Stratton will not discuss the details of the new method. He believes that more definite announcement should wait the patenting of the method. The bureau is now awaiting the arrival of apparatus needed to complete the tests before taking steps toward obtaining a patent.

Sterling Co. To Build Light Cars

BROCKTON, MASS., Aug. 3—The Sterling Motor Car Co., of Brockton, Mass., successor to the Sterling Motor Co. announces that it will begin at once the construction of 1,000 motor cars to retail, fully equipped, at $650. The company has a plant on Centre street, near Quincy, and states that 500 men will be put to work immediately. Its output for the 1915 season will be at least 5,000 cars, according to the officials of the company.

S. A. E. Council To Meet August 24-25

NEW YORK CITY, Aug. 4—The next Council meeting of the Society of Automobile Engineers is to be held August 24 and 25 at which the question of the European trip will be decided and other important matters considered. It is the idea of the officers of the society to await developments in Europe before deciding as to whether or not the European trip will be held. On August 15 the ballots will be counted in the voting as to the amendment of the constitution.

Several division meetings are in prospect, one of which will be the Electric Vehicle division. The Standards Exchange division will also meet to take up matters with the engine builders. Two respects in which standardization will be sought are in bell housings for attaching gearboxes to unit power plants and housings for attaching gearboxes to rear axles. In both these particulars there is a woeful lack of uniformity at present.

E. V. A. A. Membership Is Doubled

NEW YORK CITY, July 30—The Membership of the Electric Vehicle Assn. of America has increased about 100 per cent. since last October. Last October the membership was 437, while it is now approximately 850. The sectional representation has expanded until it now includes New England, Chicago, Philadelphia, Washington, Cincinnati, San Francisco, Los Angeles, Pittsburgh, New York City, Detroit, Cleveland and Toronto with expectations of having local sections in the immediate future in Buffalo, St. Louis and three or four other cities.

Service Bureau for Motor Truck Club

NEW YORK CITY, Aug. 3—The Motor Truck Club of America plans to operate a Legal Aid Bureau during the coming year. It will distribute copies of laws to club members, establish a school of instruction for drivers, appear in court for traffic offenders, act as legal adviser, recommend support or condemnation of proposed legislation, prepare proposed laws, gather statistics and act generally in behalf of club members.

To Build Trucks and "Cykes" in Orange, Mass.

ORANGE, MASS., Aug. 3—The old plant at Orange, Mass., used for many years by the Grout Automobile Co. for manufacturing Grout cars, has just been leased by the Orange National Bank, its owners, to a syndicate that proposes to form a corporation that will build light trucks and cyclecars. The factory has been leased for a term of years with an option to purchase the place at the expiration of this period. The new company plans to use the entire factory and it expects to begin operations in September when an announcement will be made.

Monroe Co. To Make $450 Two-Seat Light Car

FLINT, MICH., Aug. 1—A two-passenger light car to sell at $450 will be made by the Monroe Motor Co., which has been organized and incorporated with a capital stock of $250,000. The plant formerly occupied by the Imperial Wheel Co., in this city has been secured and manufacturing operations will start at once so as to begin deliveries beginning September. The first year's output is expected to be of about 5,000 cars.

The board of directors consists of R. F. Monroe, for the last three years with the Chevrolet Motor Co.; W. C. Durant, of the General Motors Co.; Arthur G. Bishop, president of the Genesee County Savings Bank; A. B. C. Hardy, general manager of the Chevrolet Motor Co.; R. T. Armstrong, of the Armstrong Mfg. Co.; Curtis R. Hathaway, of New York. Mr. Monroe is president and general manager of the new concern.

Wagenhals Experimenting with Small Car

DETROIT, MICH., Aug. 2—The Wagenhals Motor Car Co. is carrying on extensive tests with an experimental car about half the size of the machine it is manufacturing. The little machine resembles the larger one in that it has three-wheels, one in the rear. Its carrying capacity is between 400 and 500 pounds and the price will be about half of the present model. It carries a four-cylinder motor 2.75 by 4 inches.

Stepless Electric Bus Test in New York

NEW YORK CITY, Aug. 3—Regular 125-mile-a-day trips are being made in New York city by the Field stepless electric bus, with a view of proving its practicability. The New York Omnibus Co. has applied to the board of estimate for a franchise to operate Field buses on regular lines.

In its demonstrations the bus has been climbing hills of 10 per cent. grade.

In the run of 125 miles daily the bus is said to use up 220 kilowatts. The vehicle is charged for 5 hours at night and is given a 10 minute boost at the end of each 15-mile round trip.

Knox Motors Company Is Active

NEW YORK CITY, Aug. 4—In THE AUTOMOBILE for July 16, among companies which were mentioned as being out of business were the Knox Automobile Co. and the Knox Truck. These concerns have nothing to do with the present Knox Motors Co., which is actively engaged in the manufacture of passenger cars, tractors and motor fire apparatus at Springfield, Mass.

Paige Cuts Car Prices $50 and $80

DETROIT, MICH., Aug. 5—*Special Telegram*—The price of the 1915 Paige-Detroit has been reduced to $925 on model 25 and $1,195 on model 36, or, respectively, $50 and $80 less than 1914 prices.

Powers Want Federal Trucks

Federal Motor Truck Co. has been asked per cable by several European countries now at war how soon a large number of trucks could be furnished. The company has taken up the matter with the U. S. Government to find out if the declaration of neutrality will prevent such shipments.

New Denby Truck on Overland Test

DETROIT, MICH., Aug. 1—The first of the new trucks made by the Denby Motor Truck Co., of this city, started on an extensive test and advertising trip yesterday en route to Philadelphia over the Michigan and Ohio roads. Sales Director R. P. Spencer and C. D. Chenever of the export department of the Denby company are making the trip on the truck.

Signal Flags at Crossings, New Traffic Plan

NEW YORK CITY, Aug. 3—Regulation of traffic by means of flags has been tried out in New York city on Fifth avenue at Forty-second street. By raising a flag a traffic officer indicated the direction of traffic, and the same signals were given on other corners within view of the man with the flag, thus causing traffic to flow north and south at the same time and east and west at the same time on streets within the signalling area.

Market Reports for the Week

By far the most important event of the week as far as the prices of materials are concerned was the $0.27 rise in the price of tin, due to the rumor that Great Britain had barred exports of metal from the British Isles. The price is now 58 cents and will probably go higher as it seems only a question of supply and not of price. There has been practically no change noted in the other materials.

Detroit Ships 44,500 Carloads in 6 Months

Nearly 67 Per Cent. as Many Cars Shipped as in Twelve Months of 1913

DETROIT, MICH., August 4—During the first 6 months of 1914 a total of 44,500 carloads of automobiles have been shipped out of Detroit, the total number of automobiles being estimated at 189,125. During the 12 months of 1913 the total number of carloads of automobiles shipped by Detroit manufacturers totaled 66,450, the number of automobiles shipped in them being estimated at 282,412. Thus in 6 months of this year the number of carloads of automobiles handled by the railroads running into Detroit amounts to nearly 67 per cent. of the total they handled all last year.

The 5 per cent. increases in freight rates accorded the railroads by the Interstate Commerce Commission for the territory between Buffalo and Pittsburgh and the Mississippi river, affects especially the Detroit automobile manufacturers, according to traffic expert A. T. Waterfall, of the Detroit Board of Commerce, who stated that about 60 per cent. of the total tonnage of the railroads running in and out of Detroit concerns coal and coke, which are among the commodities upon which no increase of freight has been allowed, while of the remaining 40 per cent. of tonnage the automobiles come in for the larger proportion.

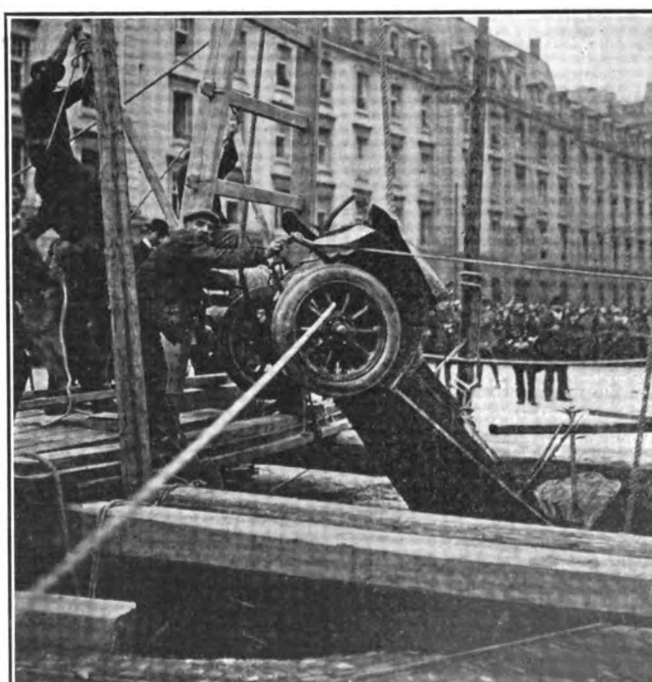
Many Concerns Hold Up Foreign Shipments

Information obtained by the Detroit Board of Commerce shows that among the forty big local manufacturing concerns which have received cable instructions to withhold all further shipments to Europe, are the manufacturers of the Chalmers, Ford, Hudson, Hupmobile, Krit, Lozier, Packard, Saxon and Studebaker cars and of the Continental motors.

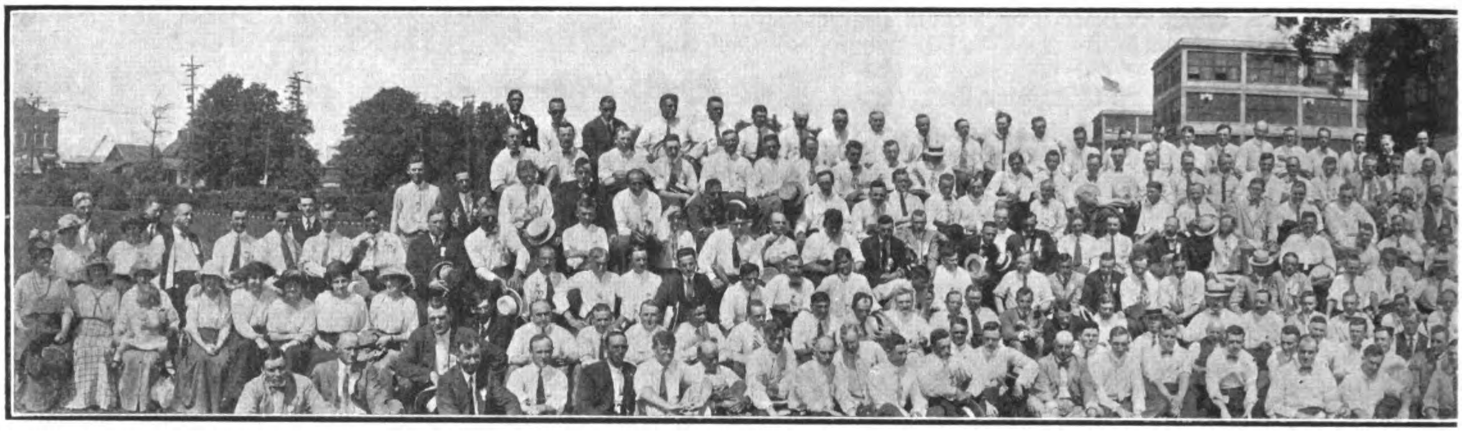
BOSTON, MASS., Aug. 1—The Leghorn Sales Co., of which George R. Leghorn is president, has been formed to act as distributors for the Lozier cars in New England. Salesrooms will be opened on Boylston street.

No Securities Quotations This Week

NEW YORK CITY, Aug. 4—Owing to the war conditions existing in Europe the New York Stock Exchange has been closed and there is no trading in securities.



In a recent cave-in of a street in Paris a taxicab was carried into the hole. The illustration shows the removal of the wreck



Gathering of nearly 500 Chalmers dealers at the factory of the company in Detroit. The meeting was very enthusiastic and a material increase

"All 1914 Cars Sold"—"Many 1915 Orders," Say New York Dealers

Branches and Agencies Find No Depression, Reporting Record Business—Buick's Extraordinary Sales—Trade Has General Gain of 50 Per Cent. Over Same Period Last Year

NEW YORK CITY, July 27—Dealers in this city report a very successful year for the sale of their 1914 model cars. A majority of the agencies are far ahead of the 1913 sales—on an average, approximately 50 per cent. The much discussed business depression does not appear to have affected them.

Many of the firms are sold out and are still having many calls for the 1914 product, which they cannot satisfy, as the factories are also all sold out and are about to announce their 1915 models.

The dealers look forward to a good business for 1915 models, one agency having already delivered 100 cars, with a standing order of 100 more. One firm sold eighteen cars retail on July 23, the largest day's sale in its history. The same firm reports the biggest year and the best outlook.

Most of the dealers have large territories, including most of New Jersey, Long Island, part of Connecticut, several counties in this state, also Staten Island, the Metropolitan district and Pike County in Pennsylvania.

Just what each dealer did last year is shown in the following extracts, giving in some cases the total sales and also the percentage of increase for the first 6 months of this year in comparison with the same period during 1913:

Buick—Biggest year it ever had, with a splendid outlook for 1915. Was sold out on May 1, 2 months earlier than last year. Sold 360 of the 1914 cars. Has sold 100 of the 1915 cars and has a standing order for 100 more. On July 23 sold eighteen cars, the largest day's sale in its history.

Cadillac—All sold out, with sales better than ever. Sixty per cent. ahead of last year. Customers calling for 1914 cars just as the 1915 model is to be announced. Is having much difficulty in supplying needs of customers. Has had to call on distributors in surrounding territories to be able to make immediate deliveries on some of the orders.

Car-Nation—Started selling on May 15. Up to date sixty-four cars have been sold. Reports very good outlook for future sales.

Chalmers—Best year it ever had, with a 50 per cent. increase. Fine outlook for 1915 models.

Chandler—June was the largest month it had. Up to July 24 sales have exceeded June. The agency has handled 10 per cent. of the factory output, amounting to 250 cars. The agency has only been going about 11 months.

Ford—Long Island plant reports a 50 per cent. increase.

Hudson—Sold twice as many cars up to July 12, this year, as sold 4 months later in 1913. During 1914 this agency sold 868 cars wholesale, and 146 retail. Increase in sales attributed to the reduction in price on its light six. The agency contracted during 1914 for 298 cars and for the 1915 season, 868 cars.

Hupmobile—During June the local agency has sold and delivered 300 cars to its sub-agents in the surrounding districts, with an increase of about 200 per cent.

Locomobile—Splendid retail sales. One of the best years in the company's history.

Marmon—Has sold fifty-seven cars since March 1, 1914, with prospects good for next season's models. Agency all sold out.

Mercer—Mercer sales are a little above those of last year. This year the agency has made less sales in cars where it has had to take second-hand cars in the trade, than in 1913.

Mitchell—The Mitchell agency reports a 150 per cent. increase. During 1914 300 cars were sold as against 125 in 1913. These 300 were sold during the first half of this year, more than the whole of last year. Predicts good sales for the latter part of 1914.

Moon—From January to June of this year, this agency has sold 182 cars, an increase of 41 per cent. over last year's sales for the same period.

Oldsmobile—Gain approximately 15 per cent. in its sales. Sold 185 cars in 1913 and 215 in 1914. Has sixty orders on the 1915 model. Has contracted for 850 cars of the 4-cylinder type for the coming year and 250 of the sixes. Predicts big year on the fours.

Overland, Peerless, Willys-Knight—Sales 33 1-3 per cent. ahead of 1913. Has ordered 3,500 cars for next year. Last of 1914 Overlands sold.

Packard—Sold out in May on 1914 models. Same sales as made in 1913. Ahead on truck orders. Sales on trucks up to July, 1914, more than any other year.

Premier, Briscoe, Lexington, Pathfinder, Ford—This agency reports good business. Though only in business for a few months sales have been very satisfactory.

Pullman—Sold seventy-five cars first 6 months of this year a 25 per cent. increase. Good sales on 1915 model.

Simplex—Same as last year. Sales on new models very good.

Stevens-Duryea—Up to May 12, 1914, sold as many as up to August 1, 1913. Better this year than ever. Especially good sales in closed cars.

S. G. V.—Increase of 10 1-2 per cent. on 1914 cars. Good 1915 prospects.

Studebaker—Good sales for 1914. Fine prospects for 1915.

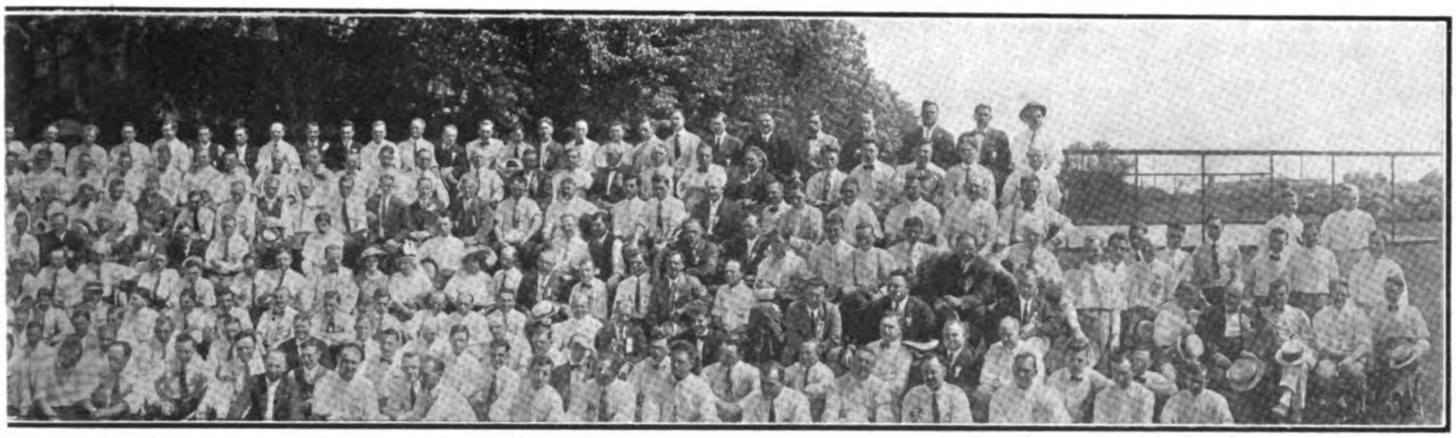
Stutz—1914 sales were much better than 1913.

Velie—From August 1 to July, 100 per cent. ahead of 1913. Sold 150 cars in 1914 and seventy-five in 1913. The truck end of business very good.

White—Sales show a very satisfactory increase over last year.

—

PONTIAC, MICH., Aug. 1—C. E. Voorhis has resigned as assistant general manager of the Kingman Plow Co., Peoria, Ill., to become assistant sales manager of the Oakland Motor Car Co., Pontiac, Mich.



in business is in prospect for 1915. Many important decisions were reached at the conference, among which was the increase in the car prices

Ohio Trade Gets Cut Rates for Compensation Insurance

Premium of 65 Cents Per $100 for Factory Workers Reduced to 60 Cents—For Chauffeurs, from $1.65 to $1.49

COLUMBUS, OHIO, Aug. 3—The Ohio Board of Awards, which has charge of the administration of the workmen's compensation law, made a number of reductions in the premium rates to be charged employers July 1. In this list, which was on the average of 5 per cent., the automobile industry benefited to a large degree. As a result thousands of dollars will be saved employers of men in garages, repair shops, taxicab companies and plants and branches.

The old rate of $1.65 per $100 of the payroll for chauffeurs has been reduced to $1.49. The old rate of 75 cents for all garage employees has been changed to 65 cents, and the old rate of 65 cents for employees of automobile plants and branches has been reduced to 60 cents.

With the law in force for a little more than two years the great benefits to be derived, not only by the employees but also the employer, are plainly seen. While there are a number of things to be adjusted the administration of the law on the whole has been very successful.

The law makes it compulsory for all employers, if firm, individual or corporation which employs five or more persons, to contribute to the state fund. Concerns employing less than five persons can come in if they wish. Those who do not want to come in are compelled to file a bond with the Ohio State Board of Awards and to make all settlements for deaths and injuries on the basis followed by the board.

Packard Dealers in Session This Week

DETROIT, MICH., Aug. 1—The Packard Motor Car Co. will hold a special "Sales Session," August 5 to 7, when over 100 dealers and sales managers from 60 cities will come to the Detroit plant. Assistant sales-manager A. E. Corbin, will speak about the changes made in the new model "3-38"; the heads of the different departments will give instructive talks and there will be a general discussion of sales problems and Packard methods of manufacture. Finally each dealer will receive his "3-38" demonstrator and will return to his home town in the car, some already having advised the Packard company that they will make a non-stop return trip.

Briggs-Detroiter Convention Optimistic

DETROIT, MICH., Aug. 1—The annual distributors' convention of the Briggs-Detroiter Co., which was held this week was attended by its principal distributors in the United States, Canada and foreign countries. All seemed very optimistic about the future outlook of the automobile business and greatly pleased with the 1915 Detroiter.

President C. S. Briggs, who presided over the out-door convention which was held under a big tent on the factory's testing grounds, announced that the output for 1915 will be at least double that of this year, the price remaining the same.

There were informal talks about all matters partaining to the Briggs selling, advertising, service and factory policies and an interchange of ideas and suggestions by the distributors.

One of the features of the convention was the presenting by the Briggs-Detroiter company to "Bob" Overstreet, of Ft. Worth, Tex., of the silver bowl and $500 in gold coins which had been put up as prizes to the distributors who disposed of the largest number of cars between May 1 and July 27. Minneapolis and Omaha were respectively second and third in the competition.

The convention ended with a banquet tendered by President C. S. Briggs to the distributors at the Detroit Boat Club.

Walpole Creditors Get 4 Per Cent. More

BOSTON, MASS., Aug. 3—An additional dividend of four per cent. has been ordered by the United States District Court in Boston for the creditors of the Walpole Tire & Rubber Co. Fifty thousand dollars has been set aside for this purpose. This makes $171,000 thus far paid.

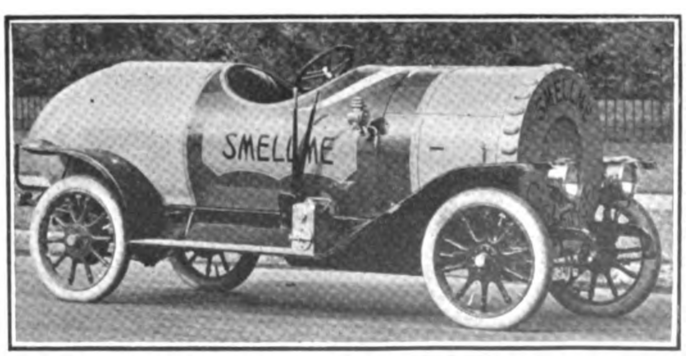
Willman, Studebaker Advertising Chief

DETROIT, MICH., Aug. 1—George L. Willman, who was assistant advertising manager when William S. Pettit was in charge of the advertising department of the Studebaker Corp., has been appointed manager of this department, while Paul Hale Bruske, who had charge of it after Mr. Pettit's departure, will devote all his time to his work as manager of the publicity department and editor of the Studebaker News. Mr. Willman was most recently connected with the Detroit Board of Commerce as its business manager.

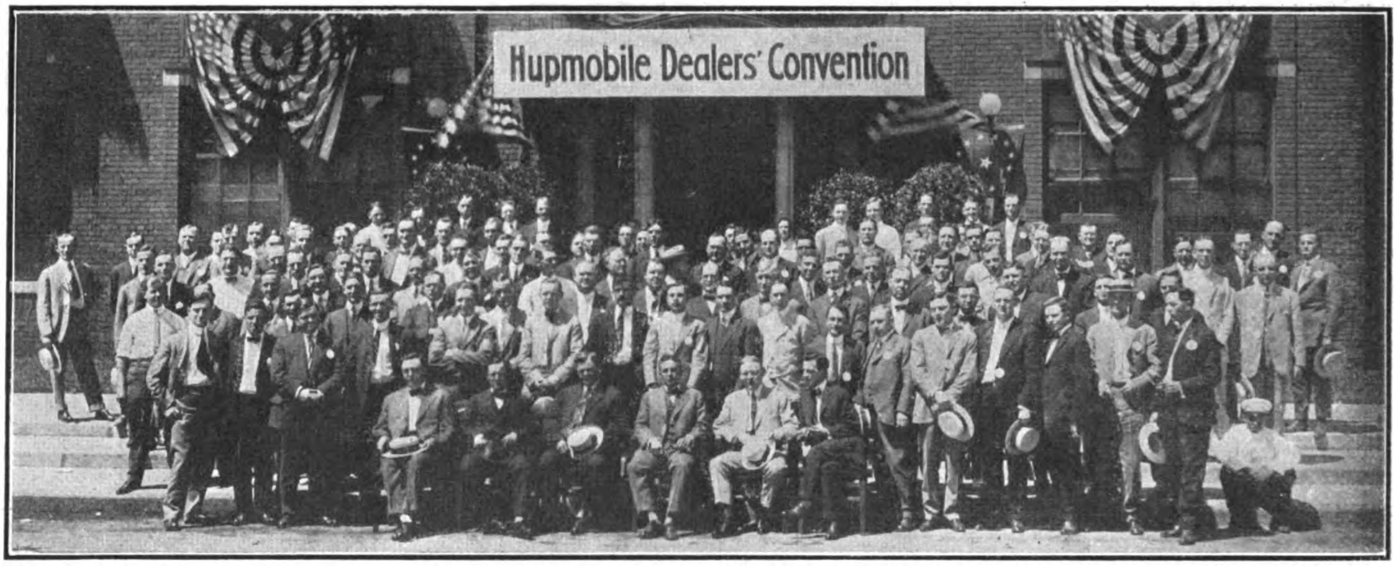
Delivery Cars Built Like Product

DETROIT, MICH., Aug. 1—The First French Perfumery Co., 931 East Jefferson avenue, Detroit, a new concern, has hit upon a clever scheme to advertise its product. The trade mark of its perfume is Smellme and the perfume itself is principally sold in metal cartridges. Two cars have been built with special metal bodies having exactly the shape of the little perfume cartridges, and bearing on both sides the trade name of the perfume. The rear part of the car is used to carry packages just as a delivery car.

The two cars left Detroit a month ago and all the large central and western cities will be visited. The cars attracted a great deal of attention on the streets of Detroit.



Novel advertising scheme devised by a Detroit perfumery company



Gathering of Hupmobile dealers during the recent convention at the factory of the company in Detroit. The meeting lasted 3 days

Klaxon Co. Sues Sparton Dealer

General Automobile Supply Company, New York City, Is Defendant—Action Due To New Patent

NEW YORK CITY, August 4—The United States Patent Office has recently issued to the Lovell-McConnell Mfg. Co., of Newark, N. J., maker of Klaxon, Klaxonet and Klaxet warning signals, patent No. 1,105,324, on application filed July 10, 1911. The claims of this patent cover the motor case with screw-thread and locking-ring adjustment, which the Klaxon company states is an important feature of all Spartan horns now on the market and of the Sparks patent No. 1,048,436, granted December 24, 1912, under which they are marketed.

It is claimed by the Lovell-McConnell Mfg. Co. that the application on which the present patent was granted was filed 10 months before Sparks filed his application. Lovell-McConnell has brought suit in the Federal Court for the Southern District of New York for infringement of this patent against the General Automobile Supply Co., a New York dealer in Sparton horns.

Newtone Maker Is Defendant with Dealer

NEW YORK CITY, July 30—Judge Veeder in the Federal Court for the Eastern District of New York has signed an order making the Automobile Supply Mfg. Co., Brooklyn, N. Y., the Newtone horn manufacturer, a party defendant in the suit brought by the Lovell-McConnell Mfg. Co., the Klaxon horn manufacturer, against Julius Bindrim, a Brooklyn dealer in automobile supplies, selling Newtone and Newtone Superior horns. The Klaxon maker claims infringement of letters patent No. 1,094,403, granted April 21, 1914. This patent was described in THE AUTOMOBILE for July 16, 1914. The plaintiff claims that the Newtone Superior horn is an infringement.

Royalty of 50 Cents on Master Vibrators

NEW YORK CITY, Aug. 4—The motion of the K-W Ignition Co., Cleveland, O., for a new appeal in the suit brought by the Unit Coil Co., Jersey City, N. J., has been denied by the United States Circuit Court of Appeals in Ohio. The Unit Coil Co. charged infringement of the Willard E. Dow patent, No. 752,384, dated February 16, 1904, for an electrical igniter for explosive engines, and the Reuben Willard, Jr., patent, No. 754,666, dated March 15, 1904, for induction coil.

The defendant was ordered to pay a royalty of 50 cents on each one of its master vibrators manufactured since March 1, 1912, and to continue this payment, the injunction against manufacture not to take effect if this condition is complied with.

Norwalk Agency Claims Territory Invasion

NEW YORK CITY, Aug. 3—The Norwalk Motor Car Co. of New York has brought suit in the United States District Court in New York city asking that the Norwalk Motor Car Co., of Martinsburg, West Va., be restrained from shipping Norwalk cars into the New York city territory. The New York Norwalk company had a distributor's contract which the manufacturer determined to terminate because of alleged violations of the agreement. The matter will be heard September 8.

Sue Grand Rapids Truck Stockholders

GRAND RAPIDS, MICH., Aug. 1—For the purpose of trying to recover more than $100,000 for the creditors of the bankrupt Grand Rapids Motor Truck Co., suit in chancery has been filed against 64 stockholders of the defunct concern by the Grand Rapids Trust Co., trustee. The trust company claims that this sum is due on capital stock issued and it also holds that the unpaid balance upon the capital stock which was contracted for, subscribed for or owned by any of the stockholders made defendant, and which balance amounts to the difference between the par value of the stock and the amount actually paid thereon, constitute an equitable asset which is liable and should go for payment to the creditors.

Refinancing for U. S. L. Co.

BUFFALO, N. Y., Aug. 3—Plans are under way for the refinancing of the United States Light & Heating Co., Niagara Falls, N. Y., which recently was placed in the hands of receivers in equity. A H. Ackerman, vice-president and general manager prior to the receivership, has been made general manager under the receivership. Assets are said to be three times the liabilities.

235 Studebaker Dealers Drive from Factory

DETROIT, MICH., July 31—It was Studebaker "Drive Away Day" Wednesday, July 29, when 235 automobile dealers from the Chicago territory who had arrived here in a special train of 12 Pullman cars in the morning, drove out in the afternoon headed for Chicago and many other Western towns in their brand new Studebaker 1915 demonstrators.

"Drive Away Day," the third which the Studebaker Corp. has arranged thus far this season, was the biggest in the history of that concern.

In the party which left Chicago on the special train were dealers from Illinois, Indiana, Iowa and Wisconsin, some located 1,000 miles from Detroit. A stop was made at South Bend, Ind., where the visitors made a tour of the various

Studebaker plants. The train reached Detroit early Wednesday morning and after breakfasting the dealers went to plant No. 1 on Piquette avenue, where the 235 new Studebaker cars were turned over to the 235 dealers who started in the the cars for Clark park. A pathfinding car took the lead on the 300-mile journey to Chicago, while a car carrying a supply of tires ended the procession.

The dealers had been asked to keep in line until South Bend, or 170 miles out of Detroit, and this they did and thus caused the country people along the route to line the roadway and remain wondering at the unusually long procession of brand new cars.

Orders Multiplied at Hupp Meeting

DETROIT, MICH., Aug. 1—The 3-day dealers' convention of the Hupp Motor Car Company came to a close Friday night when the 200 dealers and officials of the company actually inaugurated the 1915 Hupmobile business, beginning in the shape of a banquet at the Hotel Ponchartrain.

"With double the number of dealers from all over the United States and Canada in attendance and orders on hand for more Hupp cars than ever before in our history," said President J. Walter Drake, "we have every right to call this the most successful Hupp convention. As we expected, the new 1915 Hupmobile was enthusiastically received by every dealer at the meeting, so much so, that every one of them has doubled and in some cases trebled their requirements for 1915. Dealers generally report very favorably on the financial situation, both in the United States and Canada, and they are looking forward to a big year for the automobile industry. Although none of our foreign dealers were in attendance at this meeting, our foreign sales continue as one of the most important factors in our business, and we are planning a record number of shipments abroad during 1915."

Lozier Opens $100 Photograph Contest

DETROIT, MICH., August 4—The Lozier Motor Co. has promoted a photograph contest open to all with cash prizes totaling $100 of which $50 will be the first prize, $20 the second prize, while there will be three cash prizes of $5, one of $4, one of $3 and four of $2 each. The photographs must be relative to the Lozier light four and should be as much as possible live pictures showing the car at work or at play, at the seashore or in the mountains, climbing, speeding or going through the mud, in fact any picture which makes the car appear in motion. All photos should be addressed to the advertising department of the company which they must reach not later than August 25.

TORONTO, Aug. 1—Dodge Brothers, Detroit, have appointed E. P. Clarkson as their district representative for this territory.

DETROIT, MICH., Aug. 1—The Knight Tire & Rubber Co., of Canton, O., has taken over the Detroit agency and changed it into a branch. The headquarters are at 580 Woodward avenue and Fred Harrington is the manager.

Mulford Stars at Galveston Beach

Drives His Peugeot to Victory in 10 Out of 16 Events at 85 to 110 M. P. H.

GALVESTON, TEX., Aug. 4—*Special Telegram*—Ralph Mulford, whipping his big French Peugeot about the beach race course at a speed of from 85 to 110 miles per hour was the hero of the Galveston Beach races this year. Out of the sixteen events Mulford took first money in ten. He lost but one event entered and in this he was second.

His rivals for honors and money were Alley and Rickenbacher, both of whom drove big Duesenbergs and at many times pressed the winner so hard that the excitement was thrilling. In the first 50-mile event Mulford beat Alley bv 4 seconds. In the second 50-mile event he outdistanced the Duesenberg by 1 second. Rickenbacher was driving this time. In the last 50-mile race Mulford was winner by 3 minutes. The big Peugeot's time for the 150 miles, originally called the cotton carnival sweepstake race and later divided into three different events, was 138 minutes and 15 seconds.

Lecain, Tipans, Jessop, Jones and Chandler pulled down money at the races.

Three Mercers Swell Elgin Entries to 17

Concern Felt for De Palma, En Route from Germany — Practice This Week

CHICAGO, ILL., Aug. 3—Three Mercers have been added to the entry list of the Elgin road races, scheduled for August 21-22, bringing the total number of cars engaged to date to seventeen. Two of the Mercers come from the company direct, the drivers nominated being Spencer Wishart and Ed. Pullen, while the third is nominated by Ed. Schillo, the local Mercer agent, who has engaged Charles W. Luttrell, of Chicago, as pilot.

A change of entry also was made the latter part of last week. W. H. Harris, inventor of the Harris drive, which does away with the differential, has bought one of the Marmons belonging to Charles E. Erbstein, the Chicago lawyer and has taken over the entry. Mel Stringer will drive this. The seventeen, which are entered for both days, are as follows:

CAR	ENTRANT	DRIVER
Peugeot	E. J. Schroeder	Not named
Stutz	Stutz Motor Car Co	Oldfield
Stutz	Stutz Motor Car Co	Anderson

Considerable anxiety is felt over De Palma. He was scheduled to sail from a German port last Wednesday, bringing with him the Grand Prix Mercedes. He cabled Tuesday he was to get away the next day, but it is not known whether or not his steamer was one of those recalled by wireless after the war broke out.

The Kane county course is being put in the best of shape. Already it has been oiled once and the second coat will be put on this week. It is expected that informal practice will start the latter part of the week.

Labor Day Matinee for Brighton Beach

NEW YORK CITY, Aug. 3—The Motor Dealers' Contest Assn. of New York city, at a meeting this week decided to hold a matinee race meet at the Brighton Beach track Labor Day, September 7. It is hoped to secure as entries a number of the drivers in the Elgin races, August 21 and 22. George H. Robertson is chairman of the racing committee and will receive entry blanks at 1789 Broadway.

Creosote Blocks for Minneapolis Speedway

ST. PAUL, MINN., Aug. 3—The Minnesota Motor Speedway Assn. has incorporated at $1,000,000 paying a filing fee to the secretary of state of $525. The speedway is to be built between the Twin Cities. Those promoting the scheme for a 2-mile motor course are W. T. Ansley of Minneapolis, W. F. Pascle and E. H. Ehrhorn, Chicago. The promoters report they will have the motordrome ready for races next year.

Cincinnati Speedway Project Chartered

CINCINNATI, O., Aug. 4—This is the latest city to have hopes of a motor speedway. The Cincinnati Motor Speedway Co. has been incorporated at $100,000 for the purpose. The incorporators are W. T. Foley, F. D. Hirst, T. A. Tauwald, Jr., C. A. Gintor and A. H. Morrill.

Races and Run for Argentine Republic

BUENOS AIRES, ARGENTINA, July 31—Argentina has so far afforded the best South American market for European automobiles, showing that much may be done to expand American sales in her territory. It is therefore of commercial interest that the Automobile Club of Argentina has decided to hold its annual grand prize run from January 3 to 10, 1915, over the course Buenos Aires—Rosario—Cordoba and return, which represents a distance of 1,700 kilometers (1,060 miles). The going will be treated as a reliability run and the return as a race. Entries at $30 per car can be made until October 15 and at $50 up to December 15. The event is open for all cars and nations without power limit, but each vehicle must be fully equipped and carry two persons. January 7 will be given over to an excursion from Cordoba. On January 8 there will be a 1 kilometer championship race, on January 9 a race from Cordoba to Rosario, 450 kilometers, continued by another race on January 10 from Rosario to Buenos Aires, also 450 kilometers.

37 in 2-Day Ohio Reliability

COLUMBUS, O., Aug. 3—The reliability contest held under the auspices of the *Ohio State Journal*, of Columbus, O., July 30 and 31, was a success in every particular. In all thirty-seven cars started the contest from the office of the newspaper and all but one car finished the tour. The route lay through the principal cities and towns in the central part of the state as follows: Newark, Lancaster, Circleville, Washington C. H., London, Springfield, Mechanicsburg, Marysville, Marion, Mt. Vernon, Delaware and back to Columbus.

Officials and members of the Columbus Automobile Club acted as starters and checkers. Fred Boyd, in a Cole, acted as pacemaker. In all there were four classes in which prizes of cups were given to the first and second.

The winners were: Owners' Class—G. A. Wilson, London, Buick, first, and Fred C. Myers, Columbus, Great Eagle, second.

Dealers' Class, division A, cars selling under $1,250: Kaiser Motor Car company, Hupmobile, first, and The Ohio Auto Sales company, Regal, second.

Division B, cars selling from $1,251 to $2,000—Brasher Motor Car company, Cole, first, and the Standard Motor Car company, Hudson, and The Tywman Motor Car company, Interstate, tied for second place. Both contestants waived their rights to the cup which was awarded to Miss Mable Kinkead, who drove a Hudson throughout the tour.

Division C, cars selling for more than $2,000—F. E. Jolly, Pilot, first, and E. J. Thornton, Winton, second.

New Traffic Rules in Washington Aug. 10

WASHINGTON, D. C., Aug. 3—One week from today many important changes in the traffic regulations will go into effect in this city. One of the most important of the new rules is that no vehicle, except a commercial vehicle, loading or unloading, shall stand for more than 15 minutes at any place on Fourteenth and Fifteenth streets, between Pennsylvania avenue and I street, the most congested section in Washington, between the hours of 8 in the morning and 6 at night. Exception is made of government vehicles.

Another important regulation is that every horse-drawn vehicle shall have a metal tag so affixed on the right side as to be visible 20 feet. A charge of 50 cents is to be made for each tag. No vehicle horse drawn or motor propelled will be allowed to approach within 15 feet of any street car while the same is stopped or stopping for the purpose of taking on or unloading passengers, nor within such distance of the place where a passenger shall have left the street car until the passenger shall have reached a place of safety. Vehicles moving north or south will have right of way over those moving east or west.

The regulations also prohibit the use of a motor muffler cut-out as well as unnecessary or excessive smoke. Electric or acetylene headlights are prohibited on the streets unless the rear reflectors are removed or the front glass is either ground or covered with some material of sufficient density to prevent dazzling or blinding to persons using the streets.

The new regulations expressly set forth that pedestrians should avoid interference with traffic and to this end should not step from the sidewalk without first looking to see what is approaching. They are further admonished to cross the street at a right angle, preferably at a regular crossing at the end of a block and, where a traffic policeman is stationed, wait for his signal. Under the old law, which has never been enforced, pedestrians were compelled to cross a street at a regular crossing, but under the new regulations it is optional where they cross, although the regulations ask pedestrians to use the regular crossings instead of crossing at any point.

There are 80 sections in the new regulations and nearly all of them apply to motorists. Violations call for fines ranging from $1 to $40 for each offense.

Factory Miscellany

Auto Body Co. Adds—The Auto Body Co., North Lansing, Mich., has started work on the large addition to its factory building, a full force of men being at work excavating on Turner street where the new structure is to be built. When completed the addition will be flush with Turner street on the north and will be 60 feet wide by 140 feet long with an "L" on it 65 feet by 110 feet. It will be three stories high, built of brick and fully equipped with new machinery. The total ground area of the entire factory building will cover nearly two acres in the heart of North Lansing, when the new addition is completed. The company has over 400 men on its pay roll at the present time. In order to supply the factory orders a night shift consisting of men who labor in those divisions of the factory that are back in their work, has been put on.

Faultless Rubber Builds—The Faultless Rubber Co., Ashland, O., will build a three-story 80 by 120-foot factory.

Will Rebuild Havers Plant—Plans are being prepared for the rebuilding of the plant of the Havers Motor Car Co., Port Huron, Mich. The loss to the plant and equipment has been computed at $125,000.

West Lorne Motors Equipping—The West Lorne Motors Co., West Lorne, Ont., contemplates the purchase of some new equipment for the manufacture of automobiles and motor fire trucks and engines. H. A. Carmichael is manager.

Wilson Plant Nearly Completed—New plant of Wilson Tire & Rubber Co., in Harvard Park, Springfield, Ill., will be under cover within 4 weeks. Machinery will have been placed by the middle of September. The main building is 200 by 300 feet and is in the form of a hollow square, having an interior court of 100 by 200 feet.

Sphinx Co. May Soon Operate—At a recent meeting of the Sphinx Motor Car Co., held in York, Pa., plans were discussed for the beginning of operations of the new company. The several sites offered to the company for the location of its plant were discussed in detail, but no definite action was taken in the matter. Offers of real estate have been received from York, Lancaster and Reading. The new company sustained the loss of all its blue prints, drawings and specifications in the fire at the body plant of Charles K. Darone & Co. The latter concern had been awarded the contract to build the first twenty-five Sphinx bodies. The Sphinx company is capitalized at $160,000.

Ford Service Building for Fargo—Ford sales agencies in North and South Dakota and Montana will be served from a large assembling and distributing plant which is to be built at Fargo, N. D., within the next few months, according to an authoritative announcement made there this week. It is definitely stated that that branch will employ a force of about 300 men and that all Ford cars sold in the Northwestern States will be assembled there, the parts being shipped from the factory at Detroit. The site for the new plant is 120 by 150 feet, and, although the details of the plans are not known, it is said that the building is to occupy the entire site and will be three or four stories in height, making it one of the largest Ford branches in the country.

New Bosch Service Stations—The Bosch Magneto Co., New York City, has recently added to its list the following supply stations: Pollard Auto Co., 232 Main St., Nashua, N. H., J. F. Charley Auto Co., Evansville, Ind., Weeks Garage, Patchogue N. Y., C. A. Gossard Auto Co., 122-124 S. Fayette St., Washington C. H., O., Harnell Garage, Babylon, N. Y., N. J. Auto & Supply Co., 38 N. Delaware Ave., Camden, N. J., Reilly Bros. & Raub, 44-46 No. Queen St., Lancaster, Pa., Central Auto & Supply Co., Jackson, Mich., Le Jeal Cycle & Mobile Works, 1721-1723 Sassafras St., Erie, Pa., Shrive Incorporated, 64 Warburton Ave., Yonkers, N. Y., S. H. Heginbottom & Son, Saginaw, Mich., Mattoon Motor Car Co., Mattoon, Ill., Eric J. Gustafson, Rockford, Ill., Ward's Vulcanizing Works, 27 So. Main St., Concord, N. H., Lawrencville Auto Co., Lawrenceville, Ill., W. A. Sanford, 52 No. Main St., So. Norwalk, Conn., Cadillac Motor Car Co., 202 Government St., Mobile, Ala., Rippowam Garage, Stamford, Conn., and the Gibbes Machinery Co., Columbia, S. C.

Thomas Car Nearly Completed—The Thomas car of Saginaw, which Lansing builders are making is under construction at the plant of the Acme Engine Co., North Lansing, Mich. All parts of the car have been made and the assembling process is under way. The car will be on the streets about August 16. If it meets expectations, a plant will be established here for its manufacture. W. H. Porter, L. E. Rowley and a number of other prominent local men are interested in the project.

For a small car it is unique in design, having a stream-line body, pointed radiator, electric lights, left steer and center control. It will have four cylinders, water cooled with a thermo-syphon system and 18 horsepower. The rear axle will be a gearless differential and the car will have a shaft drive, sliding gear transmission, with three speeds forward and one reverse. A commodious tail box in the rear will carry all necessary equipment needed on a trip of any distance. Other specifications are a 28-inch wooden wheel, with a 3-inch tire; two side lights, a large head light in front of the radiator; motor 2¾ inch bore by 4-inch stroke.

The Automobile Calendar

Aug. 2-9	Grenoble, Automobile Club of France's 6-Day Motorcycle and Cyclecar Reliability Contest in French Alps.
Aug. 16	Le Mans, France, Automobile Club de la Sarthe's Coupé International Light-Car Race, 1 liter, 400 maximum cylinder area, 350-500 kilos weight.
Aug. 17	Le Mans, France, Auto Club de la Sarthe's Grand Prize de France for 4½ liter cars.
Aug. 21-22	Chicago, Ill., Elgin Road Races, Chicago Automobile Club.
Aug. 23	Auvergne, France, Coupé de l'Auto Race.
Aug. 27	Brooklands Track, England; Annual Automobile Race.
Aug.	Denver, Colo., 650-mile Run, Colorado Springs to Salt Lake City.
Aug.	Russia, Road Race, Coupe de l'Empereur, 2,500 miles.
Sept. 6-7	Brescia, Italy, Auto Club of Italy's 4½-liter Grand Prize.
Sept. 6-7-8	Newark, N. J., Cyclecar Reliability Tour to Atlantic City.
Sept. 7-14	Indianapolis, Ind., Automobile Show, Indianapolis Automobile Trade Assn.
Sept. 9	Corona, Cal., Road Race, Corona Auto Assn.
Sept. 10	Portsmouth, Eng., Autumn Conference, Institute of Metals.
Sept. 10-15	Berlin, Germany, German 4½-liter race.
Sept. 15-Oct. 11	New York City, Commercial Tercentenary Celebration.
Sept. 26	Brooklands Track, England, Annual Automobile Race.
Sept. 26-Oct. 6	Berlin, Germany, Automobile Show.
Oct.	Philadelphia, Pa., E. V. A. A. Annual Convention.
Oct. 4	St. Louis, Mo., Automobile Show, Auto Manufacturers' and Dealers' Assn.
Oct. 7-17	New York City Electric Vehicle Show, Grand Central Palace.
Oct. 9-Nov. 2	S. A. E. European Trip.
Oct. 16-26	Paris, France, Automobile Salon.
Oct. 17-24	Pittsburgh, Pa., Automobile Show, Auto Dealers Assn., Inc.
Oct. 19, 20, 21	Philadelphia, Pa., Elec. Veh. Assn.'s Convention.
Oct. 19-26	Atlanta, Ga., American Road Congress of the American Highway Assn. and the A. A. A.
Oct. 28-31	Milwaukee, Wis., Convention, Northwestern Road Congress, Auditorium.
Nov.	El Paso, Tex., Phoenix Road Race, El Paso Auto Club.
Nov. 6-14	London, England; Olympia Show.
Nov. 8-9	El Paso to Phoenix, Ariz., Automobile Race.
Nov. 8-11	Shreveport, La., Track Meet, Shreveport Auto Club.
Nov. 15	Paris, France, Kerosene Motor Competition.
Jan. 2-9	New York City, Annual Automobile Show, Grand Central Palace.
Jan. 23-30	Chicago, Ill., Automobile Show, First Regiment Armory.

The Week in the Industry

Motor Men in New Roles

PYKE Now in Charge—Harry N. Pyke assumed charge of the Boston branch of the Chalmers Motor Car Co. on August 1, when the Whitten-Gilmore Co. dissolved and relinquished the agency. He had been with the Chalmers Co. for 6 years, the greater part of the time at New York.

Tackerbury Joins Puritan Co.—The Puritan Mfg. Co., Detroit, has appointed W. W. Tackerbury, formerly of the Metal Products Co., as assistant general manager.

Willman Studebaker Advertising Manager—G. L. Willman has been appointed advertising manager of the Studebaker Corp., Detroit, Mich. His duties commenced August 1.

Fern Winton's Vancouver Manager—W. S. Fern, formerly of Spokane, Wash., has recently been appointed sales manager for the Winton Motor Carriage Co., at Vancouver, B. C.

Henshaw on the Sick List—Charles S. Henshaw, sales manager of the Alvan T. Fuller Co., Boston distributors of Packard cars, is just recovering from an operation for appendicitis.

J. H. Ficken in New Position—J. H. Ficken, who recently resigned from the staff of the United States Tire Co., is now on the sales staff of the Kelly Springfield Tire Co., in the New York City territory.

D. Dalton Ohio Automobile Inspector—Daniel Dalton has been appointed automobile inspector of Ohio. His duties will be to travel the state and see that all cars are properly registered and that chauffeurs are licensed.

Sidney P. Bowman to Change Quarters—The Sidney P. Bowman Co. has leased the building at 1710 Broadway, New York City, and will occupy it as an agency for Oakland automobiles as soon as alterations are completed.

Ficken Representing Kelly-Springfield Tire—J. H. Ficken has left the employ of the U. S. Tire Co., Akron, O., where he has been for a number of years, and will in the future represent the Kelly-Springfield Tire Co., in New York City.

J. Doyle Gets Dodge Detroit Branch—J. Doyle, for 6 years manager of the Detroit branch of the Ford Motor Co., and at present distributor for Saxon cars for the state of Michigan, has been selected by Dodge Bros. as their Detroit representative.

Heftler Returns from France—V. R. Heftler, president of the Zenith Carburetor Co., Detroit, Mich., returned on July 25 from a month's trip to France. While on the continent Mr. Heftler attended a gathering of factory heads from the different Zenith carbureter branch factories to discuss the business outlook for 1915 and to hold a general get-together meeting.

Paige Resigns from National—A. J. Paige, M.E., who has been assistant mechanical engineer for the National Motor Vehicle Co., Indianapolis, Ind., for over 3 years, has resigned to devote some time to the development of a new motor of his design.

New Place for Asher—A. I. Asher is having erected a new brick and concrete structure of two stories and basement at the corner of Green and Spruce streets, Worcester, Mass., which he will occupy as a salesroom and service department early this fall.

Flint Jeffery Detroit Representative—The Thos. P. Jeffery Co., Kenosha, Wis., manufacturer of the Jeffery cars, has appointed as its Detroit representative H. J. Flint, formerly manager of the Hupmobile Sales Co., and later with the Oldsmobile agency, of Detroit.

Travis at Locomobile Factory—E. A. Travis, for some time manager of the Boston Locomobile branch, has been appointed assistant sales manager at the factory at Bridgeport, Conn., and A. P. Hawes, of the local branch, has been appointed to fill the vacancy.

First Automobile Show—The first automobile show of the 1915 season will take place at Salem, N. H., during the first week in September, when Chester I. Campbell, manager of all the Boston motor shows, will have charge of a big section set aside at Rockingham Park that week, where dealers in Boston, Lowell, Lawrence, Haverhill, Nashua, Manchester and other New England cities will have a chance to exhibit their new models. It will be an outdoor show.

—

Garage and Dealers' Field

Taxicabs in Mt. Vernon—H. M. Ball has started a taxicab and automobile livery business.

Bladensburg, O., Organizes Club—The Bladensburg and Martinsburg Automobile Club was organized recently by twenty-five owners. S. C. Horn was elected president.

New Garage in Cleveland—Plans and specifications have been prepared for a four-story building at the corner of Adams and Thirteenth streets for the Roberts-Toledo Automobile Co. It will be used as a garage and salesroom.

New Garage at Brockton, Mass.—Elbridge W. Anderson, of Brockton, Mass., has had work started on a brick and concrete garage on Beach street that will accommodate 30 cars as well as having space for a repair shop.

Ohio Convicts Build Truck—The state of Ohio is now operating an automobile truck which was built by the convicts in the Ohio Penitentiary. Ohio is the first state in the Union to embark into the automobile business.

Boston Cadillac Agency Moves—The salesrooms of the Cadillac Automobile Co., Boston, Mass., have been moved to the main building, 664 Commonwealth avenue, from where the entire Cadillac business and service is now operated.

Lee Tire Makes a Move—The Boston branch of the Lee Tire and Rubber Company, that has been located at 10 Park Square ever since it was opened in that city a few years ago, has been moved to larger quarters in the Motor Mart near by.

Post Office Trucks in Cleveland—The U. S. Post Office Department has decided to install nine automobile trucks in the parcel post service in Cleveland, O., within the coming month. With this increased equipment the service will be greatly improved.

Maguire Building New Place—J. W. Maguire, Boston agent for the Pierce-Arrow, is building a new service station on the Charles River boulevard in Cambridge between the Ford and Gray & Davis plants. It will be ready for occupancy in a couple of months.

Haynes Co. Branch in San Francisco—The Haynes Automobile Co. has recently established a direct factory branch in San Francisco under the California corporation name of the Haynes Auto Sales Co., Inc., with C. H. Haynes at the head and Fred Hauger sales manager.

Harry Ford's Mission—President Harry Ford, of the Saxon Motor Car Co., is spending some time in Boston to secure a new agency for the Saxon there which was thrown on the market by the dissolution of the Whitten-Gilmore Co. He expects to sign up with a new dealer in a few days.

Willard Officers Hold Banquet—T. A. Willard, head of the Willard Storage Battery Co., Cleveland, O., and other officers of the company, tendered a banquet to thirty branch managers gathered from all parts of the country. The visitors spent a day at the plant. These meetings are held every 6 months.

New Cole Additions—A. S. Blakely, identified with the editorial end of the automobile industry, has joined the Cole Motor Car Co., Indianapolis, Ind., and will have charge of the factory publicity department. H. C. Bradfield, previously in charge of the department, has been promoted to field sales representative.

$1,000,000 Building in Montreal—Automobile interests in Montreal, Que., are planning a million-dollar automobile building. The ground floor will likely be used as a garage for members of the Automobile and Aero Club of Canada, while offices on the others floors will be occupied by automobile salesmen, supply firms, etc.

Increasing His Plant—Henry F. Walker, of Medford, Mass., who has the agency for several cars in his city, is building a large service station in the rear of his present establishment, 49 Main street, that will have accommodations for 30 cars in addition to the repair shop. The building is of concrete and will be finished in a few weeks.

Boston Lozier Secures Location—The Leghorn Motor Sales Co., formed in Boston last week to handle the Lozier, has secured salesrooms at 793 Boylston street, and after alterations are completed the company will have its formal opening Monday, August 10, when some of the Lozier factory officials will be present to give the new agency a send-off.

Accessories for the Automobilist

A ROTARY Valve Motor, Fig. 1, in which the valve is directly cooled by passing water through it, has been brought out by Henry P. T. Van Kueren, an engineer in the bureau of highways, Philadelphia, Pa. The single rotating valve serves both intake and exhaust ports in turn, the valve being cut away to allow the passage of the gases.

One of the features of the motor is the method by which the pressure on the rotating valve is varied so that when the gases are exploding the valve is held tightly, but on other strokes the pressure is reduced and thus the wear is lessened. This is effected by means of a sleeve between the piston and the cylinder, the upper part of which carries the rotary valve. Thus when an explosion occurs the pressure of the gases on this sleeve holds it tightly against the rotating valve while on the other strokes the pressure in the cylinder is slight and, therefore, the wear on the axle is reduced.

In operating the valve a silent chain is employed, it being driven from the crankshaft and passing over the magneto sprocket and an idler pulley. Thermo-syphon cooling is used.

The motor bore is 4 inches, while the stroke is 4.5. The valve is 2.5 inches in diameter, and its walls are .25 inch thick. The port areas are 3.19 square inches, or 25.4 per cent. of the piston-head area. The bearing surface between cylinder and valve is 6.16 square inches per cylinder. The motor weighs 405 pounds. Five main bearings are used and the crankshaft is 1.5 inches in diameter.

The timing is as follows: Intake opens 2.5 degrees after upper dead center, and closes 26.5 degrees after lower center; the exhaust opens 26 degrees before lower dead center, and closes 2.5 degrees before upper dead center.

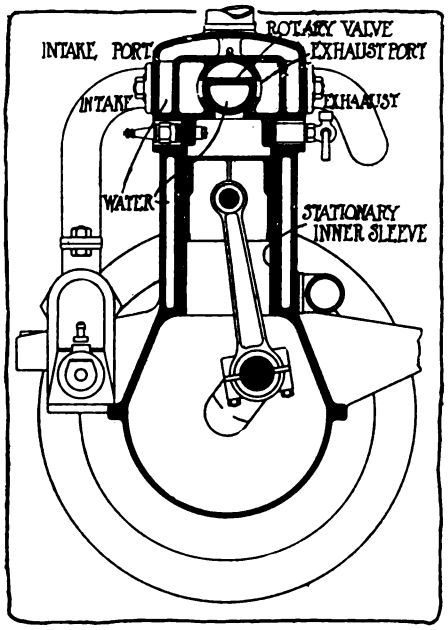

Fig. 1—Van Keuren single-sleeve, rotary valve motor

Robbins' Ford Bodies—With inclosed passenger car bodies for Ford cars being manufactured by a number of concerns and sold at a comparatively low figure, many owners of these vehicles transform the open car to a closed one at the first sign of cold weather. A line of Ford inclosed bodies is manufactured by Irvin Robbins & Co., Indianapolis, Ind., which consists of three styles, a three-passenger coupe, a four-passenger sedan and a five-passenger sedan. A commercial body is also made. These bodies sell for from $100 to $500, and because of the standard dimensions may be fitted to the Model T chassis in a short time. The Robbins bodies are said to be finished in the best fashion, having double adjusting windshields, dome lights, sashless windows, carpeted floors and many other appointments which will appeal to the owners. The illustrations in Fig. 2 show three passenger car bodies and the commercial body also.

Lane Pressed-Steel Jack—A pressed-steel jack which is light in weight, compact, easily handled and has no loose parts has been announced by Lane Bros. Co., Poughkeepsie, N. Y. This jack has a pressed-steel frame, a wrought steel lift bar and is made in three sizes—Nos. 5, 6 and 7, which weigh 4¾, 7¼ and 8 pounds respectively. The No. 5 has a capacity of 1,800 pounds and the other two 3,000 pounds, and the prices are $1.50, $2.50 and $2.75. When no weight is on the lift bar it may be dropped by pinching the trip levers without working it down, notch by notch.

Double Rubber Tubes—Inner tubes made of alternate plies of red and grey rubber, the former giving maximum elasticity and imperviousness to the air while the latter adds strength and toughness, are announced by the Double Fabric Tire Co., Auburn, Ind. It is stated that these tubes are 50 per cent. thicker than the ordinary tube. Double rubber tubes vary in price from $3.45 for the 28 by 3 size to $10.85 for the 38 by 5.5.

Gurney Ball Bearing Catalog—The Gurney Ball Bearing Co., Jamestown, N. Y., has just issued a new catalog which is descriptive of its full line of radial, radio-thrust and duplex bearings. Tables of loads and speeds that are permissible are given, and these should prove valuable to all users of ball bearings.

Haynes Dimmer—The Haynes Automobile Co., Kokomo, Ind., has offered a solution to the problem of eliminating the dazzling glare from headlights by the use of two simple devices which will be regular equipment on the new Model 30 light six car. The headlight bulbs are frosted on the upper half only, so that the rays reflected upward are diffused and softened, thus eliminating the objectionable blinding effect on drivers of passing cars in the country. The rays reflected downward through the clear glass of the bulbs are projected straight ahead onto the road.

For congested city driving, a second means is employed. The two headlights are switched into series, which action cuts down the illumination by reducing the voltage across each lamp.

Curtis Equalizing Spring System—In order to keep all four wheels on the ground at all times, Curtis & Glennon, Chicago, have brought out the device shown in Fig. 3, which consists of a beam M flexibly mounted at a point P and attached at the point A to a special shackle and at B to an arm. This arm is attached to a flat coil spring contained in the cylinder, shown, the spring absorbing most of the shock transmitted. When the car rides over rough ground the beam moves vertically and causes the spring in the cylinder to compress. With the Curtis device the frame tends to keep one position and the wheels stick

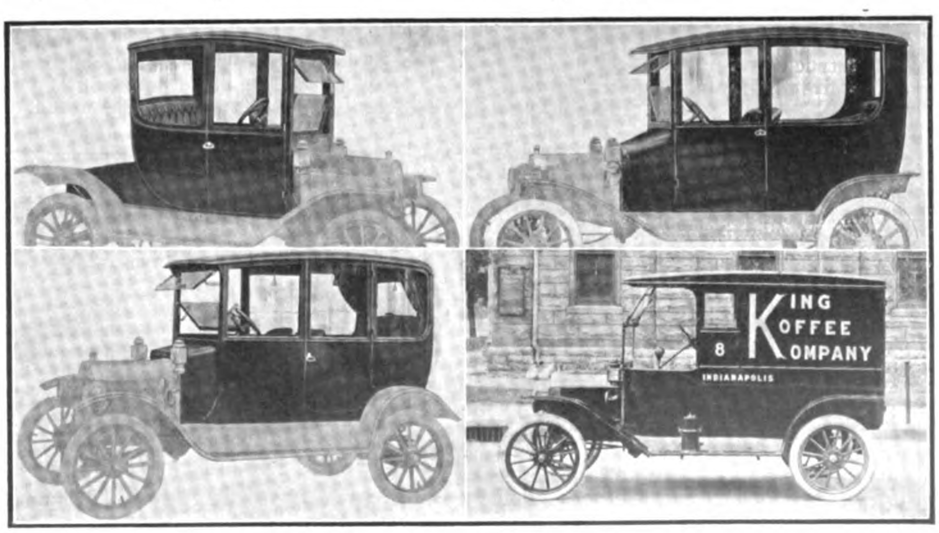

Fig. 2—Four types of bodies made by Robbins & Co., Indianapolis, Ind., for Ford cars

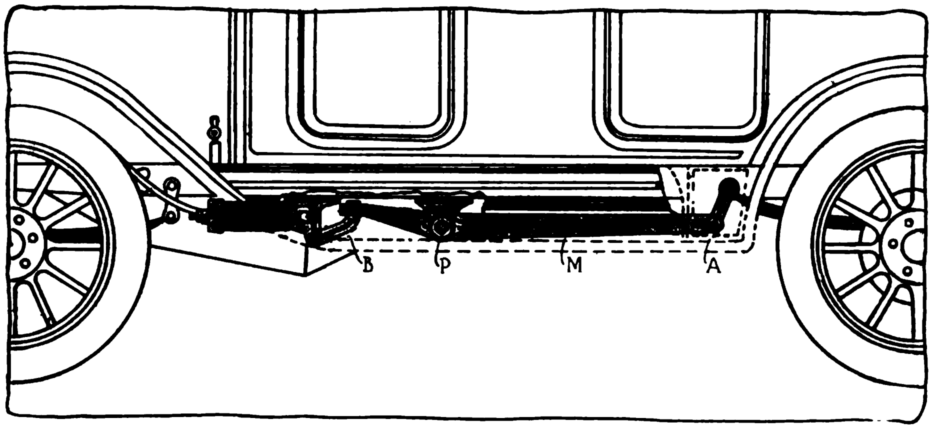

Fig. 3—Curtis equalizing spring system designed to keep the wheels from leaving the ground

to the ground. When demonstrated to an AUTOMOBILE representative the device showed good results on a 1910 Pierce-Arrow, which was driven over exceedingly rough roads at 25 miles per hour without causing the passengers to fly off the seat.

Pyralin Dimmer Goggles—A new type of goggle which is designed to protect the motorist from the blinding rays of strong headlights by darkening the upper half of the goggle is made by the Dimmer Goggle Co., Whiting, Ind. This goggle is made from a substance called pyralin, which is flexible, strong and cheap. The lower part of the goggle is amber color and the upper dark green. In the illustration, Fig. 4, three styles are shown. A having silk edges, B rubber binding, and C is a type designed especially for women.

Simplex Shock Absorber—Front and rear shock absorbers of the helical spring type are made by the Keystone Spring Works, Philadelphia, Pa. Two types are offered, one for Ford cars and another for larger machines. The former sells for $10 per set and the latter, Fig. 5, for $20. All parts are case hardened.

Jiffy-Jax Tire Savers—To prevent the deterioration of the tires due to contact with oil and water on the garage floor the Jiffy-Jack Co., Cleveland, O., has brought out a set of four jacks, Fig. 6, selling for $5, which enable the owner to quickly raise the wheels of the car from the floor. The jacks are applied to the hubs of the wheels and a single movement of the jack lever raises the wheel.

Goodyear S. V. Tire—A feature of the Goodyear S. V. Truck tire is the economy to the truck owner.

The first and most noticeable item is the total absence of steel fastenings of any kind. The first cost on fastenings for a truck tire of the demountable type ranges from $3 to $7 per wheel, and on the old style pressed-on type, the supplemental band may cost from $3 to $9 per wheel. Taking the most popular size tires, this charge for steel equipment represents about ten per cent. of the total cost of the tire, or in other words, the purchase of an S. V. tire can be considered as a ten per cent. reduction in price, it is stated.

The weight of the steel fastenings in the case of a demountable type tire, or the weight of the supplemental band in the old style pressed-on tire is great enough to represent an additional yearly expense of well over a hundred dollars when the cost of carrying it around is estimated at fifteen cents per ton mile. The economy idea is further driven home

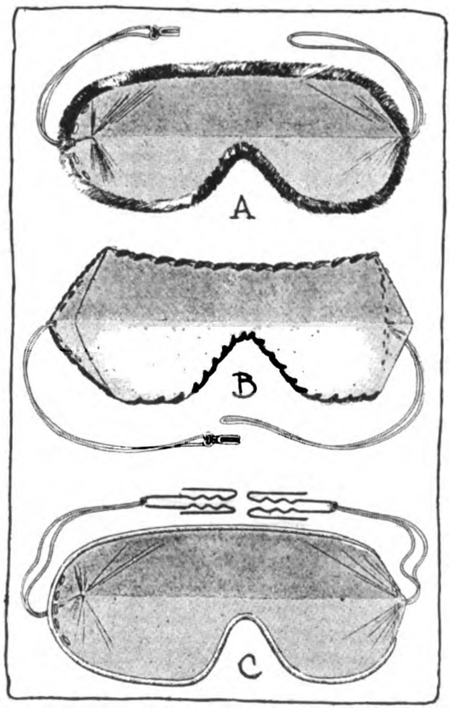

Fig. 4—Three types of Pyralin goggles

by the fact that the additional weight referred to is not borne by the springs.

Ajax Dimmer—Most of the dimming devices brought out recently are applicable only to electric headlights, but the Ajax, Fig. 7, made by the Wanner Mfg. Co., Chicago, is designed for use on acetylene burning lamps and consists of a disk of dull-finished steel interposed between the burner and the reflector.

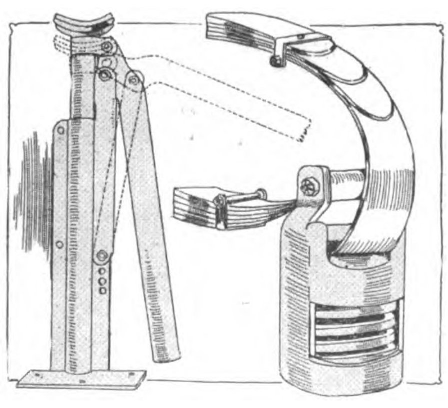

Fig. 5—Right—Simplex shock absorber
Fig. 6—Left—Jiffy-Jax tire savers

The disk is fitted to a thumb screw clamp attached to the base of the burner and when it is desired to dim the lamps the thumb screw is loosened and the disk turned so that it lies between the reflector and the gas light. The Ajax sells for $1 per pair.

Buell Explosion Whistle—A whistle, Fig. 8, made by the Buell Mfg. Co., Chicago, Ill., is installed in the explosion chamber of the motor and utilizes the high pressure of the explosion to blow it, the principle being the same as a steam whistle on a boiler using high-pressure steam. It is generally screwed into one of the unused valve caps, but when a spark plug hole only is available a fitting as shown in the photograph is used to carry both spark plug and whistle valve. Theoretically it is not good practice to lift the spark plug the ¾ inch this fitting does, but in practice the loss is so slight it cannot be noticed. The chief advantages of this whistle are the particularly effective pulsating note it produces, the absolute certainty of its operation, its self-cleaning features due to the high pressure used, and its extreme simplicity and ease of installation.

Compac Tents—The Compac Tent Co., Indianapolis, Ind., is marketing a tent made especially for motorists. The Compac tent forms a simple means of shelter and can be carried around on the runningboard of the car, for it occupies a small space, as shown in Fig. 9. No poles are required for erection and the tent can be set up on either side or at the rear of a car. The floor of the tent is made of the same material as the tent and by stuffing grass, etc., under this floor, the use of ordinary cots is not necessary. Compac tents are made in a variety of materials, the prices ranging from $31.50 for the 7 by 5 foot size to $48.30 for the 7 by 10 foot.

The Automobile

United States Has 1,548,350 Cars

Registration to July 1 Shows Gain of 294,485 in First 6 Months of 1914

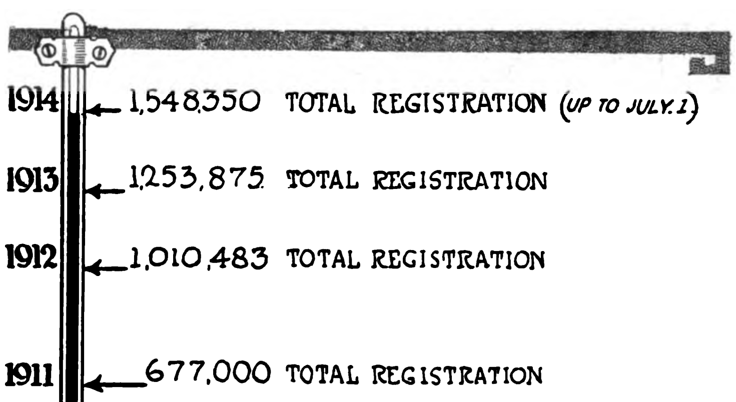
By Donald McLeod Lay

FROM all indications, the year 1914 will be one of the greatest in the history of the automobile industry. Surprising as were the gains in other years, 1914 bids fair to surpass them all, for the registration officials of the various states report increases in nearly every instance, the total registration for the United States amounting to 1,548,350 automobiles and motor trucks up to July 1. These figures, of course, include both the gasoline and electric vehicles as well as a number of steam machines. In arriving at this total all cases of duplicate registration, due to the registration of non-residents in the various states and re-registration upon transfer of ownership, are subtracted.

On January 1, 1914, allowing for all duplicate registration, there were 1,253,875 cars and trucks in use in the United States. By July 1, there had been an increase of 294,485 over this figure, a gain which is particularly surprising and significant when all the talk of hard times, lack of prosperity, etc., is considered.

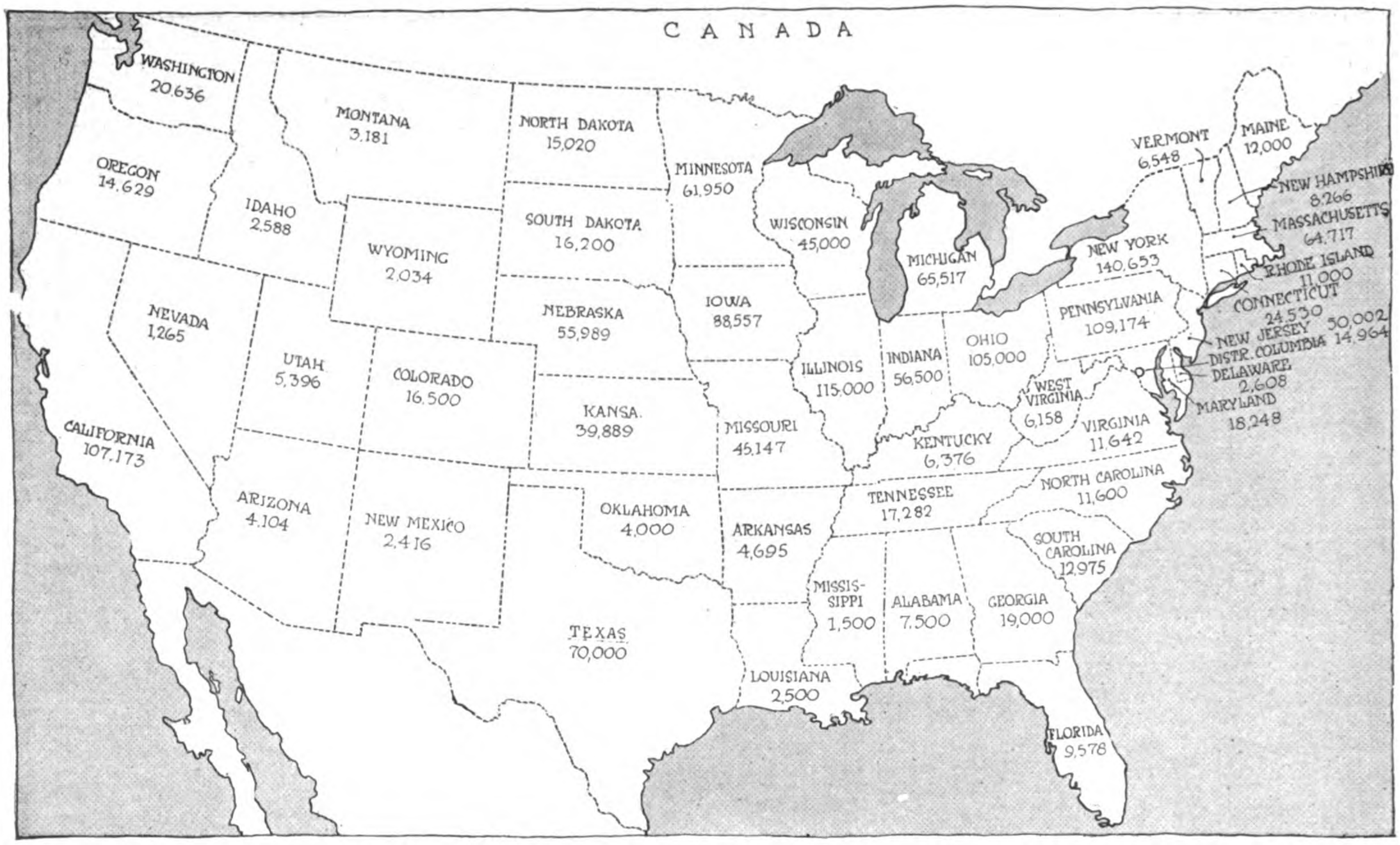
From the number of new registrations during the first half of 1914 it is apparent that the people of the United States have been buying cars in even greater quantities than ever before. The increase in the number of automobile owners is especially noticeable in the smaller communities and on the farms. In fact, the tremendous amount of money invested in automobiles and accessories in several of the states has drawn the attention of prominent business men and produced a strong impression upon the banking fraternity.

The present standing of the states in respect to the number of automobiles and motor trucks may be seen by referring to the tabulation on this page. New York still leads the van with 140,653, after all duplicate registrations have been allowed for, a



New York	140,653	Oregon	14,629
Illinois	115,000	South Carolina	12,975
Pennsylvania	109,174	Maine	12,000
California	107,173	Virginia	11,642
Ohio	105,000	North Carolina	11,600
Iowa	88,557	Rhode Island	11,000
Texas	70,000	Florida	9,578
Michigan	65,517	New Hampshire	8,266
Massachusetts	64,717	Alabama	7,500
Minnesota	61,958	Vermont	6,548
Indiana	56,500	Kentucky	6,376
Nebraska	55,989	West Virginia	6,158
New Jersey	50,002	Utah	5,396
Missouri	45,147	Arkansas	4,695
Wisconsin	45,000	Arizona	4,104
Kansas	39,889	Oklahoma	4,000
Connecticut	24,530	Montana	3,181
Washington	20,636	Delaware	2,608
Georgia	19,000	Idaho	2,588
Maryland	18 248	Louisiana	2,500
Tennessee	17,282	New Mexico	2,416
Colorado	16,500	Wyoming	2,034
South Dakota	16,206	Mississippi	1,500
North Dakota	15,020	Nevada	1,265
Dis. of Columbia	14,964	Total	1,548,350

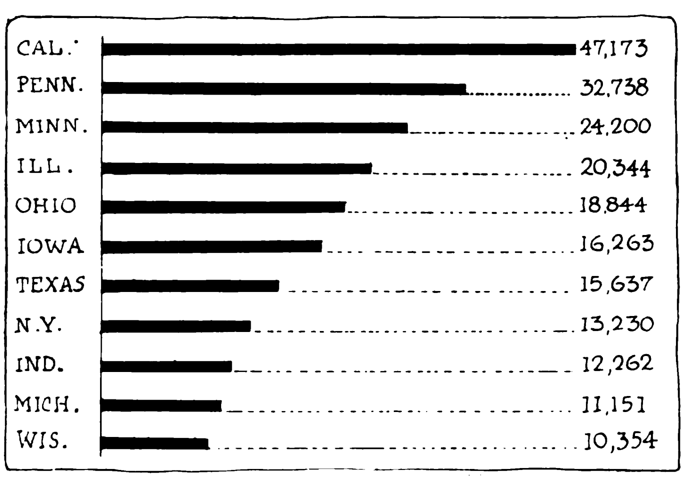
Registration to July 1, 1914, allowing for duplicate registration



Map showing actual registration of automobiles and trucks up to July 1, 1914, excluding duplicate registrations

gain of 13,230. Illinois proudly claims second place with 115,000, an increase of 20,344. A startling change, however, has taken place after this. Pennsylvania has sprung into third place with 109,174, taking first place according to the proportion of gain among all the states with 32,738. The figures given for California up to January 1, 1914, were incomplete, owing to the fact that a new law went into effect last fall and the registration of the cars in that state had not been completed by that time, the registrations being given as only 60,000. Under the new law, however, California stands fourth in rank, the registrations amounting to 107,173, allowing for duplicate registrations. The apparent increase of 47,173 is misleading in that both the new registrations and those which had not been completed under the new law up to January 1 are included.

Ohio, which stood third at the beginning of this year is now in fifth place with 105,000 cars and trucks, an increase of 18,844 in 6 months.



Eleven states showed increases of over 10,000 cars. The California figures, however, are misleading, owing to the new law

Iowa, which was fifth on January 1, is now in sixth place with 88,557, an increase of 16,263. The farmers in this state have been buying cars in great quantities, so much so that the president of a railroad which has lines in this state made a public statement a few weeks ago to the effect that Iowa people are spending more money for automobiles and accessories than for railroad fares inside the state. He went on to say that the public is more interested in the price of rubber than in the price of steel rails and more interested in good highways than in good railroads. Such a statement as this coming from such a source may be taken as strikingly indicative of the progress which Iowa is making as an automobile state.

Texas Shows Big Gain

Texas is one of those states which unfortunately has no state automobile registration and consequently it is not easy to obtain statistics regarding the number of cars and trucks in use in the Lone Star commonwealth. The Dallas Chamber of Commerce, however, made a census of the state for this purpose last fall and at that time reported that there were 54,363 cars in use in Texas. In response to a letter from THE AUTOMOBILE, the Chamber reported that while no census has yet been made for the first half of 1914, it is positive that 70,000 is a very conservative figure for the number of cars and trucks in use in Texas up to July 1. This puts the state in seventh place and credits it with a gain of 15,637 cars and trucks. On January 1, Texas was credited with 54,363 cars, which gave it ninth place.

Michigan, which stood eighth on January 1, retains its old position with 65,517 cars, an increase of 11,151.

Massachusetts, which was sixth at the beginning of the year, is now ninth, but with 64,717 cars, compared with 61,746, a gain of 2,971.

Minnesota has shown an unexpected increase, jumping from fourteenth place at the beginning of the year to tenth place July 1 with 61,950 machines registered, a gain of 24,200, putting the state second in the order of gains for the first 6 months, the abnormal figures for California not considered.

Three other states have registrations of over 50,000, Nebraska having 55,989, an increase of 8,715 over the figures for the first of the year, Indiana which is credited with 56,500, or 12,262 more than on January 1, and New Jersey, which is still barely over the mark, having 50,002, an increase of 489 for 6 months.

Three other states have over 35,000 cars, Missouri having 45,147, Wisconsin 45,000 and Kansas 39,889. The rest of the states taper down from Connecticut with 24,530 and Washington with 20,636 to Mississippi with 1,500 and Nevada with 1,265. Nevada has always had the last position in the order of registrations, but is now beginning to show some promise of mounting a little higher in the table, having gained 134 cars in the first 6 months of 1914.

Little Improvement in Laws

The automobile law situation is but little improved this year. Two of the states, California and Kentucky, are under new laws and several of the other states are making or are contemplating making changes in their motor vehicle legislation. Among these is Massachusetts, which has recently enacted some amendments to its statutes. The Michigan law is in the uncomfortable predicament of being declared invalid by the State Supreme Court, so a new act will have to be drawn for that state. The District of Columbia, Florida and Texas are still licensing cars perennially, that is, each car is licensed but once and not every year as is the case in most of the states. Minnesota has triennial registration, that is,

War Closes French Car Factories

Activity Is Confined to Aeroplane Plants—American Manufacturers Have Orders Cancelled—Tire Prices Go Up—Big Demand for Cars Here, However

War Booms English Trade

By J. Sidney Critchley, President of the Institution of Automobile Engineers

By Western Union Cable

LONDON, ENGLAND, Aug. 11—The position of the industry here is being severely tried. All private sales are for the present dead, and all programs for 1915 are at present in abeyance. Many passenger cars are being bought for war purposes which will keep some factories busily employed for the time being.

Export trade, in view of the seas being open, it is anticipated will be maintained or even increased when permission to export cars can be obtained.

Due to most of continental factories being closed or working exclusively for governments, continental agents here are absolutely cut off from supplies. Supplies of materials from Belgium, France and Germany are no longer available. All manufacturers will be compelled to rely on home materials. For example, the stock of Bosch magnetos is very limited and all available supplies will be required for commercial vehicles.

The great demand for commercial vehicles for transport will keep this branch of the industry very busy as large numbers both new and second-hand have been taken over, including some hundreds of London omnibuses.

The withdrawal of horses also increases the demand for commercial vehicles.

This branch will have a booming time, but output may be retarded by lack of materials and restricted output of passenger vehicles must prevail.—Sidney Critchley.

NEW YORK CITY, Aug. 12—*Direct news from Paris, France, of the effect on the French automobile industry* of the prospects of war—Our Paris correspondent gives some information of what the actual declaration of war ere this has caused. On August 1 all purchasing by the factories stopped, and where cars were ordered, but had not been delivered, customers were refusing to take them.

Workmen were being discharged from all factories, and in many cases production was so low that the department heads were taking inventory.

In further commenting on the situation, W. F. Bradley, resident correspondent of THE AUTOMOBILE in Paris, writes under date of August 1:

"*Should war break out the result will be to close three-quarters of the automobile factories in France.* Not only would the demand cease with the breaking out of hostilities, but in very many cases so many men would be called up for military duty that it would be impossible to run the works. In one particular factory every foreman and head of a department was required to do duty as a soldier within a week of the call to mobilize, and some of these men had to be at their post within twenty-four hours of the call.

"Activity is confined to the aeroplane and aeroplane motor factories. The section of the Renault factory producing aeroplane motors is under army control; the same applies to the whole of the Gnome motor works, as well as to the Le Rhone factory. Aeroplane builders, as well as aeroplane motor manufacturers are forbidden to supply private customers.

"Everything necessary has been done to put practically the whole of the Paris motorbuses at the service of the army at a moment's notice should the call come. These vehicles would be rapidly transformed to act as meat wagons. Automobile truck owners, having subsidized vehicles, have received intimation to hold them in readiness for delivery to the military authorities at any time.

"A close inspection has been made in the various factories of the different types of cars which could be seized for army requirements if war breaks out. These cars would be used for carrying staff officers and would be driven by factory mechanics acting as military reservists. A considerable increase has been made to the reserves of gasoline, lubricating oil and automobile tires held by the army authorities."

Accessory Business Injured

American manufacturers have already felt the effects of the European war. Two or three large accessory manufacturers have received cable orders to cancel all shipments to Europe, and their branch houses in such cities as London, Paris and Berlin have been closed.

With automobile manufacturers the situation is somewhat worse, because buying has practically ceased in all the belligerent countries. It is a case of demand as well as supply returning to zero in less than a week. Several American makers today find themselves with cars for European shipment on hand. Several of these makers build chassis with right-hand steering for Europe and left-hand steering for the domestic market. It will be difficult to dispose of these vehicles unless attention is turned to the South American market where the rules of the roads in some places call for the steering wheel on the right side.

Many representatives of the American industry are at present in Europe where they have gone on different missions, some to inspect the foreign plants, and others on pleasure trips. Little, if any, concern need be given for them as the situation has greatly clarified so far as tourists are concerned since the opening of the war.

Tire Prices Up

In America the tire situation has been affected more directly than any other, as a result of the war, due to the fact that practically all crude rubber, coming from either Ceylon and the Straits Settlements, is brought in English bottoms, and until the British navy is prepared to protect its mercantile marine there will undoubtedly be a shortage of rubber and the price which has already jumped from 55 cents to $1.12 may go much higher. Nearly 70 per cent. of American rubber comes from the East, and it would be difficult to get supplies so long as commerce on the high seas is hampered. Fortunately the touring season is near an end, July and August being the heaviest months, but in spite of this the situation is not desirable, as the tire makers are short on stock, being practically at the close of the 1914 season, and there is little crude on hand in New York City, and very little in London and little in transport. Many of the rubber companies report a stock on hand adequate for 30 to 60 days. They are already shutting off on manufacture.

Our Southwestern Market

With the foreign market in Europe closed by the war American manufacturers are looking about for other fields. Owing to the good crops in the southwestern district, there is certain to be greater prosperity and more car buying than formerly. In the southwest territory adjacent to Kansas City, the farmers have just completed harvesting the crop of winter wheat which is 50 per cent. larger than any other previous year, and as the prosperity of that section depends almost entirely upon that one crop, the value of this to the automobile industry is apparent.

In 1913 the value of the wheat in Kansas alone—all of which is in the Kansas City territory—totalled about $50,000,000. This year conservative estimates of the final value of the 180,000,000 bushels produced in that state place it at $120,000,000. In 1912 the value was $70,000,000 and in no single year has it ever gone above the $100,000,000 mark.

Eighty dealers in Kansas City will handle the motor cars that will be sold in Kansas, northern Oklahoma, southern Nebraska and western Missouri. Fifty-five others will handle the tires and accessories.

At this time stocks are down to a minimum and large shipments are being received daily from the factory. The figures of the Kansas City Motor Car Dealers' Association show that 100 cars a day are being shipped into that city.

The local Buick agency expects to sell 1,000 cars before January 1. Its 1914 business already shows an increase of 25 per cent. over the corresponding months of 1913 and it is now 125 carloads behind its orders.

The Moriarty Motor Co., Lozier, Abbott, Regal and Detroit, will sell 300 cars before January 1. Its 1914 business is ahead of its 1913 sales.

The local Overland factory branch sold 2,048 cars in the fiscal year ending August 1, an increase of 512 cars over its sales of the previous year. It has asked for 3,500 cars for its business during the next 12 months.

The Bond Motor Co, handling the Maxwell until August 1 and now the Oldsmobile, reports a 50 per cent. increase for its business so far this year.

The Velie company has prepared for a 25 per cent. increase during the next six months.

The fiscal year of the Ford company closes on October 1. During the ten months from October 1, 1913, to August 1, 1914, its sales increased exactly 45 per cent. over the sales of the previous 12 months. The company expects to reach a final increase for the fiscal year of 1914 of 65 per cent. Plans are being made to double the capacity of the Kansas City assembling plant.

The 1914 business of the Studebaker shows an increase of 250 cars sold during 1914, or a total of 1,450. An increase or 25 per cent. is expected during the next season.

The Hudson-Brace Motor Co. (Hudson) sold 200 more cars this year than last and estimate they will handle forty to forty-five cars a month until the first of January.

The Hupmobile agency sold 600 cars during the twelve months ending August 1 and are making preparations to increase that number to 800 during the next year.

This increase of sales has brought about the construction of enlarged buildings for the Kansas City branches. The Overland, Case and Jackson companies already have moved into especially designed and constructed buildings. The Hupmobile and the branches of the Republic and Federal tire companies have commenced the construction of new and enlarged quarters. Other firms are remodeling their buildings.

Carl G. Fisher and Party Escape War

President of Speedway and Prest-O-Lite Co. Reaches Home—Racing Drivers in French Army—Factories Active

INDIANAPOLIS, IND., Aug. 11—*Special Telegram*—Carl G. Fisher, president of the Indianapolis Motor Speedway and of the Prest-O-Lite Co., reached home this morning accompanied by Mrs. Fisher and John Aitken of the National company, having escaped from the European war. The party came back on the White Star liner *Laurantic*, an English ship, which landed at Montreal Saturday.

"We were just 6 hours ahead of the war net," says Mr. Fisher. "We had some trouble getting away, but it pales into insignificance when compared with the difficulties others are having. There must be at least 100,000 Americans trying to get home.

"We were at Le Mans when the war cloud broke, prepared to watch the running of the little Grand Prix. We lost no time in hurrying to England, whence we sailed on the *Laurantic*.

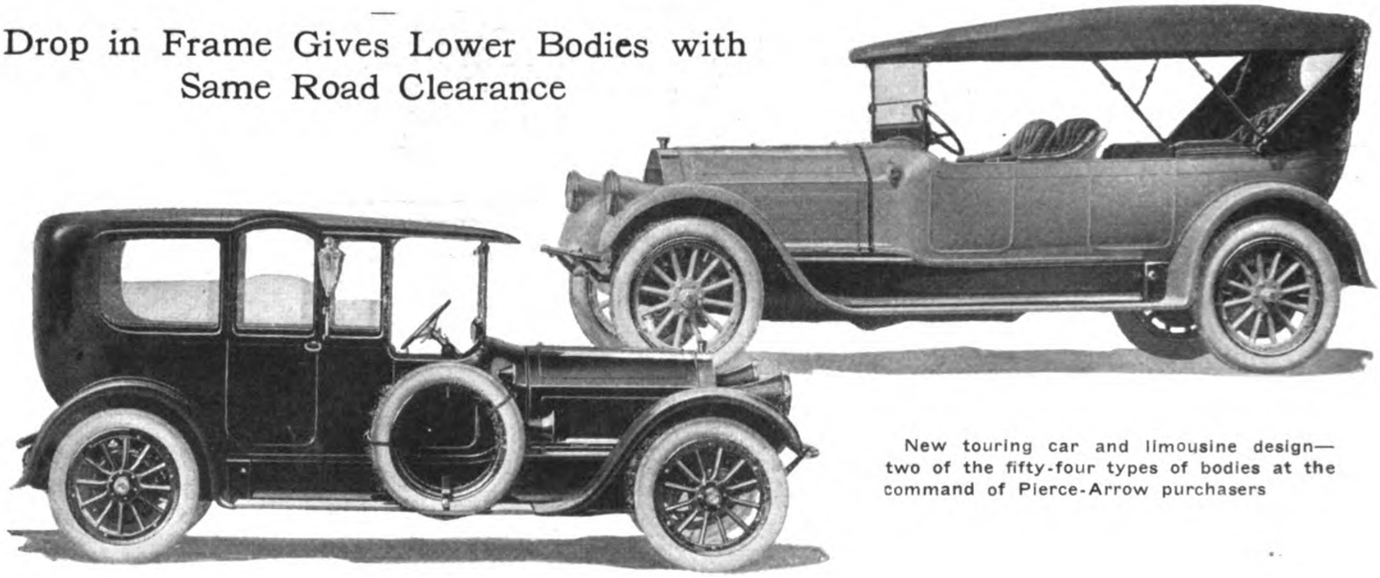
"It looks as if the war would last for some time. In England they are not confiscating motor cars, but I understand they are in Germany and several other countries. The war is demonstrating to everyone just how valuable the automobile is; in fact, it is invaluable. The various governments find it particularly adaptable to the troops. They can load fifty soldiers in one motor truck and move them faster than they can by freight train.

"The foreign motor car factories will not be shut down for the reason that their products are needed for war purposes. But the factories are greatly handicapped by so many of the workmen being reservists. Boillot is aide de camp and driver for the generalissimo of the French army, Goux is a mine layer in the army, while Thomas, winner of the last 500-mile race is an aviator in the French army.

"As to what effect this will have on the next 500-mile race it is hard to say. However, I look for the war to be over by that time. There will be enough of the foreign cars to insure European representation while I look for more American cars then ever."

Pierce Offers 54 Body Types

Drop in Frame Gives Lower Bodies with Same Road Clearance



New touring car and limousine design—two of the fifty-four types of bodies at the command of Pierce-Arrow purchasers

ONE primary change has been made in the Pierce-Arrow series three cars as compared to the preceding model known as the series two. This has been a drop in the central portion of the frame. With this single change the entire appearance of the new line has been altered and in connection with its adoption one or two other minor changes have been necessitated. The principal alteration that has come up on account of the dropped frame has been the abandonment of the gravity gasoline feed and the substitution of a pressure feed system with the gasoline tank at the rear of the chassis. The introduction of the pressure feed has in turn caused a change in the raising of the carbureter and hence an increase in its accessibility. Prices are:

	38-C 3	48-B 3	66-A 3
Touring	$4,300	$5,000	$6,000
Five-passenger	4,300	4,900	5,900
Roadster	4,300	4,900	5,900
Limousine	5,200	6,000	7,000
Vestibule brougham	5,350	6,200	7,200

With but one exception, no change has been made in the prices. The one exception concerns the largest limousine which now lists at $7,000 instead of $7,100. The prices of the other models remain as before.

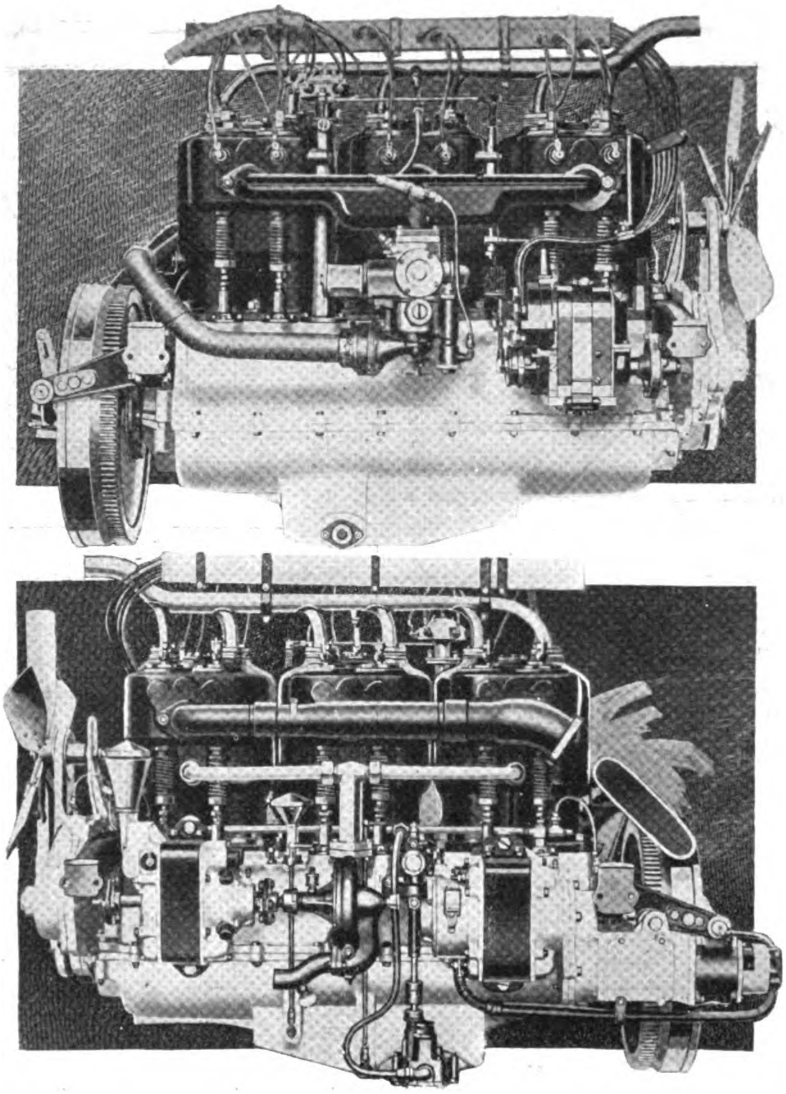
On all three of the sixes which compose the Pierce line it has been found possible on account of the increase in drop of the frame to lower the bodies and running boards without reducing the road clearance. There are also a number of other minor chassis changes which are designed to increase the convenience and comforts of the driver. The control members, including the accelerator, hand throttle and spark control, have been simplified; the electric starter is operated by a single push button on the dash in place of a pedal and, in place of the plugs heretofore used, a Yale lock is provided for the bank of switches. The engine cannot be started if the bonnet is locked and the key removed from the ignition switch. The engine primer has been simplified and the housing of the universal joint between the clutch and the gearbox has now been extended to cover the entire mechanism.

It is in the body work that the Pierce company offers an exceptionally wide choice to the purchaser. There are fifty-four body types and a practically unlimited number of color schemes to choose from. The Pierce company states that in offering such a wide range of choice it is excelling in variety even the foreign builder who sells his chassis separately. All of these bodies are entirely new in design. The standard brougham, landaulet, suburban and landau bodies have rounded corners, domed roof and in general lines which have been kept simple but at the same time follow the stream design of up-to-date practice. In addition to these standard types there are many modifications and combinations of different design. The brougham-landaulet and the suburban-landau are arranged with unusually wide side windows, and are built with only flat roofs. All standard dome roof designs have arch doors. All standard and optional flat

Divided front seat used in Pierce-Arrow series three touring car roof designs are built without the arch doors.

In addition to the different body designs and to the general improvement in appearance by reason of the lower cars, many noticeable features stand out in the new models. In fact the Pierce-Arrow Co. states that this new model has more power, a better get-away, more speed, greater comfort and more style than any other model turned out by the company. The increase in power and pick-up is ascribed to the force-feed gasoline system and the style and appearance to the lowering of the bodies.

The fenders are of new and wider design and are calculated to give better protection against mud and water than formerly. A Pierce top which has been named a Solitaire because it can be operated by one person is standard equipment on all the touring cars. The standard touring cars are fitted with individual front seats arranged with a space between to give easy passage from the front to the rear compartment. An undivided front seat will be provided if specified at no extra cost. All Pierce cars continue to be built with right drive and right control as in all the former models.



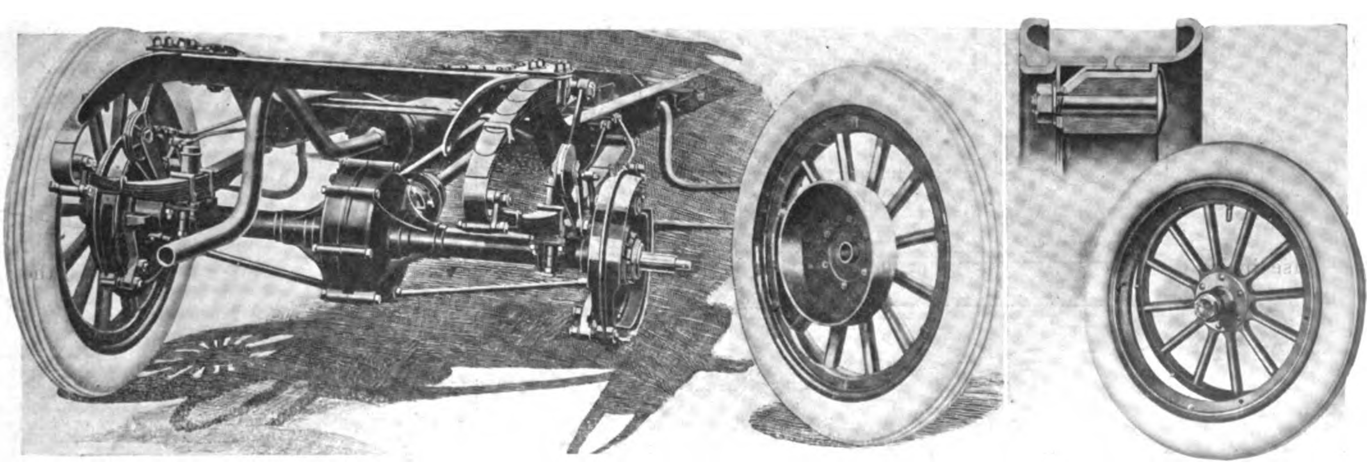
Left and right side of the six-cylinder Pierce-Arrow motor. All three sizes are similar in design

Two electric lights are provided in the backs of the touring car front seats to light the tonneau steps. The tail light and license illuminator are now combined in a unit and a rear bumper protects the gasoline tank against collision. The headlights are carried on the front fenders as in series two, but they have been moulded into the fenders with a more graceful curve and are now one of the most perceptible points of difference between the series two and series three models.

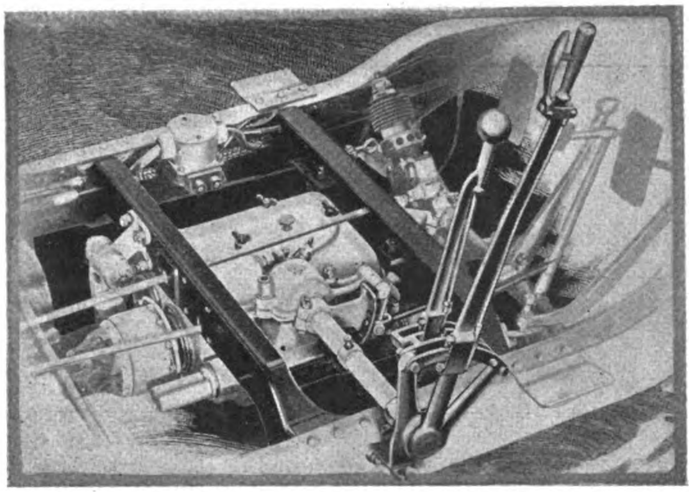
All three Pierce-Arrows are built along similar lines. The 66-horsepower is known as the 66 A-3; the 48 as the 48 B-3 and the 38 as the 38 C-3. The power plants of all these chassis are, of course, different in size, the largest being 5 by 7 inches; the 48, 4.5 by 5.5, and the 38, 4 by 5.5 inches. With the exception of the differences in size, lines of design of these three models are entirely similar and a description of the Pierce-Arrow product can be hence given as a unit.

All three engines are six-cylinder types with the cylinders cast in pairs and have interchangeable inlet and exhaust valves located on opposite sides of the cylinders. The object in keeping the T-head design, according to the Pierce engineers, is to keep the valve area large and at the same time to maintain as short an overall length as possible. The crankshafts are provided with seven bearings and each bearing is lined with a white bearing metal that is imported from England. The bearing bushings are carried within a bronze shell and the white metal is cast directly into this shell.

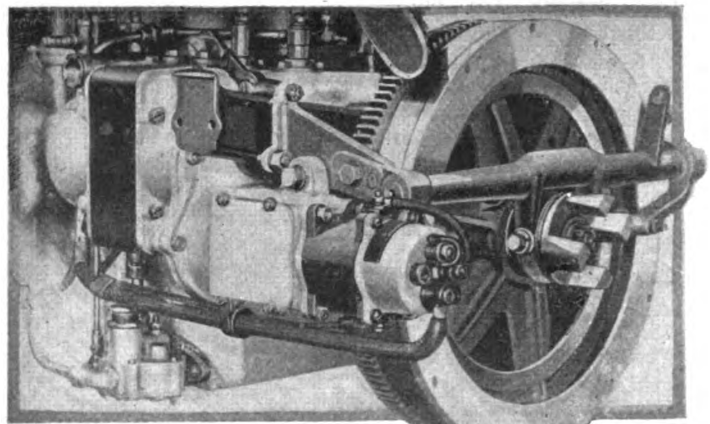
The pistons have their wristpins at about the center and carry three rings above this point. At the bottom of this piston there is a wiper ring for distributing the oil. The connecting-rods are I-beam in section and are held at their lower point by bearings lined with the same material as is used in the main bearings. One point in Pierce-Arrow prac-



Left—Rear construction of the Pierce, showing running gear, springing and torque members. Right—Construction of the Johnson patent demountable rim



Pierce four-speed gearbox mounted amidships



Mounting of the generator and cranking motor

tice which is considerably different from that generally employed is the use of a built-up camshaft. The cams are pinned to the shaft and the Pierce company states that out of 165,000 camshafts they know of less than ten cases in which the holding pins have sheared or become loose giving a percentage of failure of less than .005 per cent.

Lubrication is by force feed. The oil is carried in a reservoir beneath the crankcase. A gear pump driven off the camshaft forces the oil through a long horizontal tube from which it is distributed to the two end and central main bearings and to the timing gear case. From the bearings to which the oil is pumped it passes by means of the hollow crankshaft to the other main bearings and to the big end bearings of the connecting-rod. At each of these points there is a hollow core through which the oil is forced to the bearing surfaces. The connecting-rods carry leads up which the oil passes to the wristpin bearings and through the hollow wristpins to the walls of the cylinders. On the end of the horizontal main oil lead, there is a pressure gauge which registers the pressure under which the oil is being fed. This system is designed to be positive and to vary uniformly with the speed of the motor. While there is no splashing of the oil all the interior parts of the motor are reached by the spray thrown off by the connecting-rods through centrifugal force.

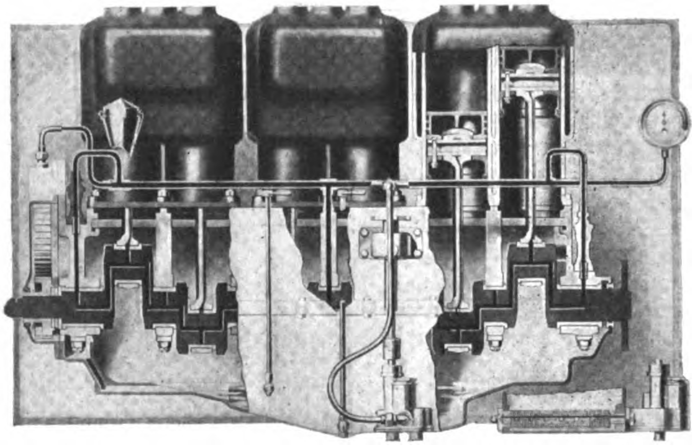


Diagram of the Pierce oiling system

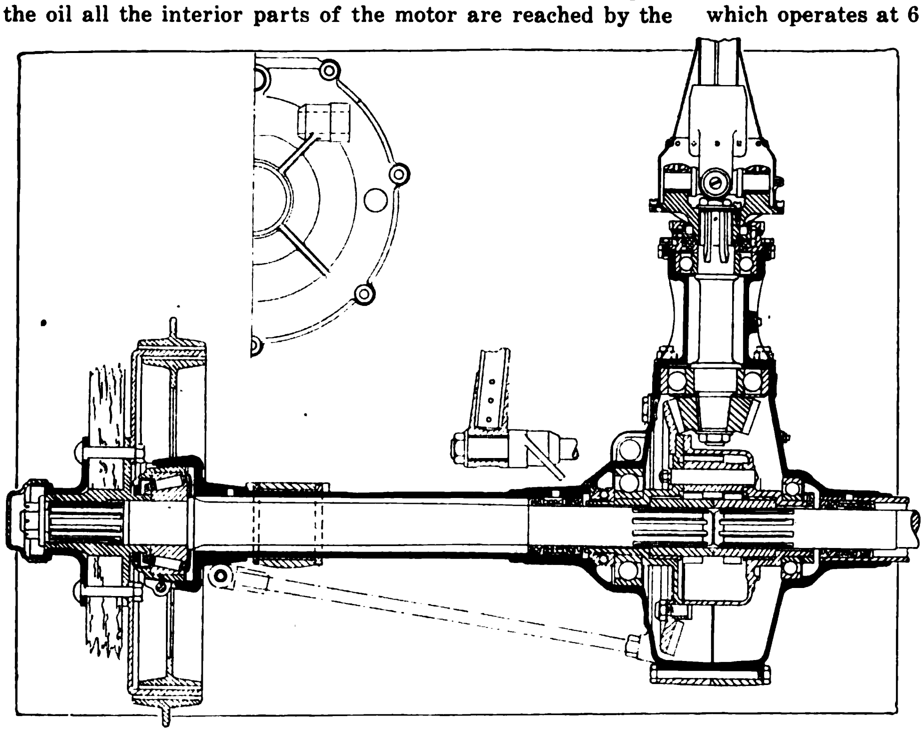
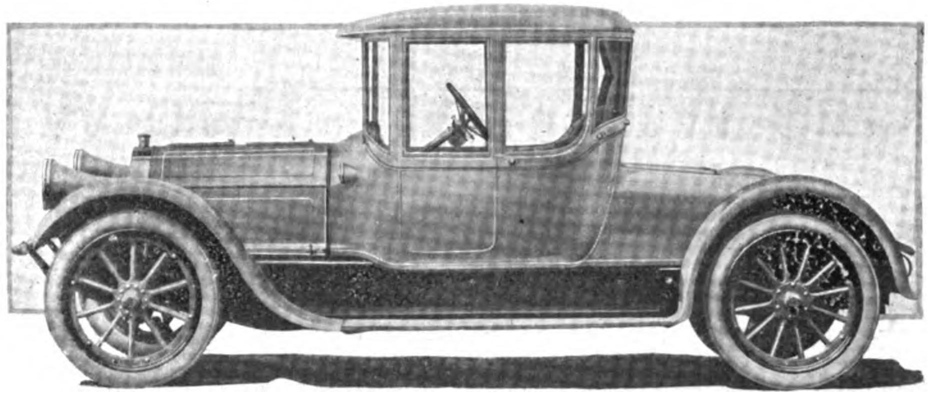
The electrical equipment includes a starting and lighting system and two independent ignition systems. Starting and lighting are taken care of by a Westinghouse two-unit outfit which operates at 6 volts. All the wiring throughout the car is done by the single-wire system, the return conductors being carried in copper tubes attached to the frame. The ground connections are soldered to the copper tubes and in connection with the chassis frame form the feed conductors of the circuits. An over-running clutch breaks the connection between the cranking motor and the engine when the crankshaft is driven under the impulses of the engine. A feature which is of importance in the installation of the starting system is the incasing of all electrical units such as the gears, shifting rods, starting switch, etc. The main source of ignition current is provided by a Bosch magneto, while for the secondary ignition system the storage battery is used as a source of current supply through separate induction coils and commutators.

The gasoline system has been entirely revamped. The carbureter is the same in all essential details but the jet sizes, for instance, had to be changed in shifting from the gravity to the



View showing the construction of the semi-floating rear axle pressure feed. Owing to the higher position of the carbureter there is no possible danger of recondensation of the fuel in the upper part of the manifold and the result has been a car with a much quicker pick-up than previously. The Pierce gasoline tank will now be found on the rear of the car and the objection to this position, namely, its liability to damage, has been answered by the application of the rear bumper.

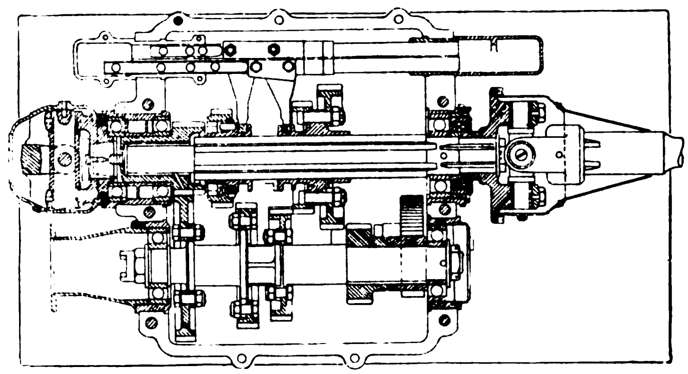


Side view of the latest design in Pierce coupés

Power is transmitted from the motor to the running gear through a cone clutch. Pierce clutch design is distinctive in that it is kept constantly lubricated by means of an oil ring so designed that a small quantity of neat's foot oil is held constantly in contact with the leather. In order to gain additional smoothness, flat springs are placed beneath the leather surface of the clutch.

Four speeds are provided. The gearset is a sliding selective design held in an aluminum alloy case. This case is divided into two separate sections to permit of ease in assembly and to cut down to the limit repair costs. The gears are carried upon cylindrical six-spline shafts and the material of which they are made is chrome-nickel steel. In finishing these gears they are held to a limit of .0005 inch in order that the total backlash through the entire train of gears is a minimum. An interlocking device is also fitted which renders it impossible to change speed while the clutch is engaged. The same interlock also prevents two gears from being meshed at the same time. An air pump for inflating tires is connected through a clutch to the gearbox countershaft.

The shaft drive is provided with a universal at both ends and also a sliding joint at the rear to compensate for the vertical free motions. There is a torque rod also for taking the drive and this is fitted with a spring cushioned and swivelled front support and a pivoted rear connection to take all the torsional strains. The order in which the drive is taken through this transmission scheme is first through the front universal joint, then through the shaft, sliding joint, rear universal joint, beveled pinion shaft and then through the beveled pinion and gear into the differential.



Constructional view of the gearbox

The universal joints are of the cross and yoke type with nickel steel pins, steel yokes and bronze bushes. The rear end of the driveshaft is hollow and splined, the splines sliding in corresponding flutes in the rear universal joint, thus providing the compensation for the rising and falling of the chassis due to the action of the rear springs. Lubrication of the sliding joint is provided by means of a charge of grease which is contained in the hollow end of the driveshaft.

The beveled pinion shaft housing is entirely separate from the main axle housing, but it is bolted securely to the latter. The pinion shaft is carried on two annular ball bearings designed to take both radial and thrust reactions from the bevel pinion. The bevel gears are of chrome-nickel steel.

The rear axle is a semi-floating design, the axle shaft being of chrome nickel steel and ground to size in order to give it the maximum torsional strength. The axle housing, incasing the driving shafts, is of nickel steel, brazed and riveted into the pressed steel housings inclosing bevel gear and differential assembly.

The front axle is an I-beam having a long drop which commences directly at the steering knuckle and sweeps into the center of the axle in a gradual curve. The steering torque rod is at the level of the lower part of the axle and the steering gear itself is a multiple screw and nut type of semi-irreversible design. The gear ratio of the steering gear is such as to provide a reduction of 1.5 to 1 in favor of the driver.

Equipment is more luxurious than

Section through the motor showing details of construction

One-Wire vs. Two-Wire Systems

By W. H. Conant

Member Electrical Equipment Division Society of Automobile Engineers

THERE is danger that serious misunderstanding may arise concerning this problem of proper wiring systems for gasoline cars. There are really two questions:

1—SHALL THE S. A. E. ADOPT ANY STANDARD FOR WIRING SYSTEMS?

2—SHALL THE STANDARD WHEN ADOPTED CALL FOR A REGULAR DOUBLE-CONDUCTOR WIRING OR A SINGLE WIRE WITH GROUNDED RETURN?

First, then, why should the Society—which is equivalent to saying the automobile industry—adopt *any* wiring standard?

The use of electric wires in motor cars has been a gradual evolution from the period in which ignition was obtained solely from dry cells and spark coil. Plain "Annunciator wire was used with its cotton thread covering dipped in paraffin. It is a far cry from that to the present-day method of installing the best rubber-covered stranded cable in metal conduits with junction boxes and other approved fittings.

Standard Lamp Base

That lamps and sockets might be had in the open market at better prices, a standard form of lamp base was adopted with uniform dimensions. As in the case of all adopted standards, this brought out considerable difference of opinion and agreement was reached only after consideration of all viewpoints.

Difficulty has been experienced in obtaining proper insulation for two contacts in these standard receptacles but as it has developed that there is ample room to thoroughly insulate and connect *one* conductor in the space allowed, many car makers have ordered lamps and sockets so designed.

We have, therefore, many thousands of lamp bulbs and receptacles in use of both kinds which are not, of course, interchangeable. Car owners are not able, as a result of this situation, to obtain lamps or other electrical fittings with as great facility or economy as if there were but one standard.

As improved economy in design and manufacture is an aim of the S. A. E., it would seem entirely proper that it *do* adopt a standard as outlined.

The Short-Circuit Argument

Consider the arguments advanced in favor of each system over the other:

Those who oppose the one-wire plan base their objections largely on the matter of safety from fire. They contend that with the entire frame and body acting as one of the two conductors, or being in such electrical contact that they *may* so act, the danger from short-circuit is very great. If a short-circuit occurs with the large current-carrying capacity formed by the frame and large wire, the storage battery capacity is such for short periods that very serious arcs, or flashes of electrical fire, may be formed and the car destroyed by fire or the individual injured.

The claim is made that many chances are offered for producing such short circuits by means of a wrench or screw-driver in attempting to make connections or adjustments. It has even been said that the chances of accident are not twice as much with one-wire, as with two, but *fifty* times as great. The figure fifty, of course, is used arbitrarily to emphasize the point, as much difficulty would be experienced in trying to determine the exact value of this factor.

Exponents of the two-wire plan claim that the history of electrical development proves the wisdom of double conductors and that the exceptions of street railways and third-rail locomotives, which use grounded returns, are irrelevant comparisons because the apparatus is cared for and operated only by trained men.

Two-Wire Arguments

They further state that users of single-wire outfits have found it necessary to install fuses in all their circuits and point to this as a proof of danger to be encountered.

A further claim is that if lamp brackets become loose, poor contact results causing lights to flicker. This assumes that brackets really carry current as part of the return circuit. It is also said that with so-called dual magnetos a grounded return scheme is not practical.

So much, then, for one side of the case and it should be noted that the writer is not expressing an opinion either way in this article but is endeavoring to make clear the opposing views and reasons therefor. In no report of the recent discussion at Cape May has there been presented the real reasons in *favor* of single-wire systems and one publication has gone so far as to use its editorial columns against *any* standard. Because of the unfortunate hour at which this matter was discussed and the small attendance at that late hour, very little of the reasons *favoring* one-wire were presented at the S. A. E. Summer Meeting.

Economy a Factor

No electrical man approaches this subject with any leaning toward grounded circuits. It smacks too much of call-bells, gas lighting and self-winding clocks—that is to say, crude beginnings of a great art. It is evident that good reasons must have convinced those electrical engineers who now favor this form of wiring for automobiles. That motor car makers, mechanical engineers and business men should favor it has no bearing on the merits of the question, for they may consider *only* economy. If, however, economy means manufacturing facility and production stimulant, their views become increasingly vital.

Socket Small for Two Wires

THE TWO-WIRE PLAN IS OPPOSED BECAUSE OF THE CLAIM THAT IT IS NOT POSSIBLE TO HAVE WORKMAN-LIKE CONNECTIONS AND PROPER CONTACT IN PRESENT SOCKETS WHERE TWO CONDUCTORS MUST BE HANDLED IN SUCH SMALL SPACE.

Much trouble is experienced in making the original installations and in keeping it free from defects in service. If a corresponding amount of trouble were given by ignition or carburetion, it must be admitted that co-operative efforts to correct it would be welcomed by all concerned. Such trouble is not found, however, where a single contact is used in this same socket. Ample room is left for proper insulation and for making a substantial wire connection.

Both Need Fuses

With two conductors so close together as is necessary in the space allowed, the ease with which a short-circuit may be found is striking. In fact, it is extremely difficult *not* to cause a short-circuit with screw driver, soldering iron or other tool in working on the apparatus. This shows that the danger from fire is present with *either* system and leads to the point that fuses should always be used regardless of the type of wiring. The need for fuses, then, with one-wire system is no argument against it and the neglect of two-wire advocates to recognize the need of fuses in their outfits is no reason for overlooking the importance of this safeguard.

Lamp Brackets No Carriers

It is commonly understood by "grounded-return" that current is conducted to the lamp, or other device, by a single wire and returns thence through the bracket and frame. Present day systems have modified that plan so that only the name remains. The wire is carried in a metal conduit—preferably copper—from which it is properly insulated. This conduit is in itself the return conductor and is only grounded, or connected to the frame, to prevent any potential difference between it and other metal parts of the car. From this it is evident that lamp brackets do *not* carry current and would not cause the lights to flicker by becoming loose.

Larger Wires Possible

As large wires are necessary to avoid appreciable drop in voltage between battery and electrical devices, the use of one wire permits of a large one being installed in a conduit of reasonable size. To use two wires of this desirable size would require a much larger conduit. The difference in cost would be determined partly by the extra wire and partly by the more expensive conduit. The ease with which connections are made to sockets is a further advantage.

Might does not make right but it is claimed that a decisive majority of automobile manufacturers has adopted the one-wire system and an overwhelming percentage of all 1915 cars will be thus equipped.

The purpose of this article is to focus attention upon the subject that it may receive the attention necessary to a proper decision when next it is considered for action. NOTHING CAN BE GAINED BY CONTINUING BOTH SYSTEMS TO THE DISADVANTAGE OF PUBLIC AND PURCHASING AGENTS ALIKE AND THE EARLY ACCEPTANCE OF ONE AS RECOMMENDED PRACTICE WILL SIMPLIFY A NUMBER OF PROBLEMS.

The S. A. E. Committee's Object

It should be stated that the Electrical Equipment Division of the S. A. E. Standards Committee did not expect to rest content with the simple recommendation for a particular system. It looked upon this action as the first step in a program of suggesting improved details of sockets, contacts and other items included in wiring outfits. If it could be understood how thoroughly this committee had canvassed the entire situation, approaching it without any preconceived prejudices, more consideration would be given its report. That the question has been up for over 2 years with many discussions by able, competent and experienced engineers from all branches of the industry, should carry weight with those who may have considered the subject but superficially and briefly.

Motor Comparisons Absurd

The statement that a six- or a four-cylinder motor might as well be proposed for standard practice is little short of absurd, even for an exaggerated illustration. The history of motor car standards is replete with similar objections to every advance that has been made. It is well to bear in mind that while an active opposition or minority, is necessary to keel the majority working along the right lines, no opposition is ever *constructive.* No amount of selecting things *not* to standardize will help in any way the great work the Society has been and is doing. No industry has ever been so benefited by co-operative labors nor has it ever been thought possible to so discuss, compromise or standardize details and methods as has been the case in this American automobile industry.

800-Mile Wireless Outfit on White Truck

A portable wireless outfit that can be set up in 12 minutes and is capable of sending messages over a radius of 800 miles under favorable conditions and receiving messages from points 2,500-miles distant, has been built for field service in the United States Army by the White Co., Cleveland, O.

Umbrella-type antennas are used, this part of the outfit being mounted at the top of an 85-foot mast which is built in nine sections. The top section is raised by hand but the others are hoisted aloft by a block and tackle suspended from struts mounted on a platform on the roof of the truck. These struts are quickly detachable when not in use. The guy wires are attached to the fifth section of the mast. When disassembled, the nine sections are carried in compartments built along each side of the truck. The counterpoise or artificial ground, consists of a heavy insulated wire. For convenience in grounding, there is a socket on the outside of the truck body into which a ground-wire fits.

The great range of the new equipment and the speed with which it may be brought into action is due to the employment of a powerful electric generator driven by the gasoline motor through a train of gears. The generator delivers electric current of 500 cycles at 110 volts and has a capacity of from 18 to 32 amperes. This current is interrupted by a relay, operated by the sending key, and is transformed so that it leaves the truck at a pressure of 22,000 volts and an amperage varying 8 to 12. As the current rises to the top of the antennas the voltage rises to approximately 90,000, while the amperage approaches zero.

Special Small Car Garages Will Reduce Rent

EDITOR THE AUTOMOBILE:—The cost of garaging is the greatest factor hindering the extended use of the small car and cyclecar in the city, and the solution of the problem would seem to be separate garages for these machines.

Garage rent is now the largest item in figuring the cost of operation, and it is therefore important to reduce this to a minimum. It is of greater moment than fuel or tire economy.

The objection to storing these small cars in garages that are designed for automobiles of all sizes is that the floor space is so laid out that the small machines take up just as much space as the large ones. The ordinary garage is laid out into a certain number of rectangles, each one of which is of sufficient size to accommodate the largest car, and therefore a cyclecar with 36-inch tread and 100-inch wheelbase will occupy this space sufficiently to prevent any utilization being made of the remainder of it. For this reason the garage proprietor is reluctant to reduce the rental he has set for this space, although he will to a certain extent, especially if he is anxious to get the business, because the average owner has an idea that the amount paid should be proportionate to the size of the car, not thinking that the small machine takes up as much room as the large one.

The answer to this problem is special garages, or special floors in the garages now in use, for the accommodation of small cars exclusively, and the floor space can be laid out accordingly, the spaces being both narrower and shorter. Then the rental can be reduced proportionately with the result that many of us who are wondering whether we can afford a small car or a cyclecar will then feel able to stand the expense.

New York City. CYCLECAR.

Motor, Long Idle, Balks

Editor THE AUTOMOBILE:—I have a six-cylinder motor which has just been carefully overhauled and placed in first class condition, but I cannot get a single explosion, even on a prime subjected to a good hot spark. This engine has been idle for nearly a year and in this time has probably gone stale. I feel that all it needs is a few explosions to warm it up and lend it a little life. What I wish to find out is if you know of any chemical, such as ether, that would explode very easily. If so what are the proper mixtures. The method I use to turn this motor over enables me to spin the engine at one-third the speed that I turn the crank. Is this too slow?

New York City. WALTER BOWLES.

—Ether vaporizes more readily than gasoline, but for that matter you might use acetylene gas.

However, your motor should start readily on gasoline and there is no reason for using ether, acetylene gas or some other makeshift in warm weather, although there might be in cold.

It would seem that the reason your motor refuses to start is that you crank it at too low a speed. With the crank attached directly to crankshaft, spin the motor after priming the cylinders with gasoline.

Possibly the spark plugs are dirty or moist so that the sparks are short-circuited. Clean the spark plugs thoroughly in this case. Also see that the carbureter is in adjustment.

There is no such thing as a motor going stale and with a good spark in each cylinder and a proper mixture your motor should start without trouble.

Simple Method of Spreading Gravel

Editor THE AUTOMOBILE:—Fig. 1 shows a simple method that I saw employed recently to spread gravel or crushed stone to an even depth. This saved two or three laborers. The truck is a 5-ton Peerless with dumping body.

The device is a catch, made in a blacksmith shop, which will permit the truck tail gate to swing open only a certain number of inches. It has three steps, one of which spreads the load, with the truck in first speed, at a depth of 6 inches, another 8 inches and another 10 inches. It works equally well on up or down grade or on the level. The accompanying photograph shows the results that are obtained.

Bexar, Tex. H. A. CALMAN.

How to Adjust Rayfield G

Editor THE AUTOMOBILE—Will you please give me a full description of the adjustments of the new G3 Rayfield carbureter?

South Bethlehem, Pa. SUBSCRIBER.

The adjustment of the new G 3 Rayfield resembles largely that of the model C described in THE AUTOMOBILE for July 16, 1914, the difference being that there is no air-valve adjustment. All model G carbureters are the same, the numeral appended indicating the size.

When adjusting a Rayfield carbureter, Fig. 2, bear in mind that all adjustments are turned to the right for a richer mixture.

Before adjusting the carbureter be positive there are no obstructions in the gasoline line; that manifold connections are absolutely tight and free from air leaks; that valves and ignition are properly timed, and there is a hot spark and good compression in all cylinders.

With throttle closed and dash control down, close the nozzle needle by turning the low-speed adjustment to the left until block Y slightly leaves contact with the cam M. Then turn to the right about one and one-half turns. Open the throttle not more than one-quarter. Prime the carbureter by pulling steadily for a few seconds on the priming lever G. Start the motor and allow it to run until warmed up. With retarded spark, close the throttle until the motor runs slowly without stopping. Turn the low-speed adjustment to the left one notch at a time until the motor idles smoothly. If the motor does not throttle low enough, turn the stop arm screw A to the left until it runs at the lowest number of revolutions desired.

Then advance the spark about one-quarter and open the throttle rather quickly. Should the motor back-fire it indicates a lean mixture. Correct this by turning the high-speed adjusting screw to the right about one-quarter turn at a time until the throttle can be opened quickly without back-firing. Should the motor not back-fire, turn the high-speed adjusting screw to the left until it does. Then turn to the right until the motor runs smoothly and powerfully.

Adjustments made for high speed will in no way affect the low speed. If loading (choking) is experienced when running under heavy load with throttle wide open, it indicates too rich a mixture. This can be overcome by turning the high-speed adjustment to the left.

The low-speed adjustment must not be used to get a correct mixture at intermediate or high speeds. The automatic air valve should always be seated when the motor is throttled down to its lowest speed.

Before starting the motor when cold observe the following instructions: Open the throttle not more than one-quarter (if opened more starting will be difficult); enrich the mixture by pulling up the dash control; prime the carbureter well by pulling on priming lever G for a few seconds. When stopping the motor pull up the dash control. Open the throttle about one-quarter and switch off the ignition. This leaves a rich mixture in the motor, which insures easy starting.

Why Racers Use Castor Oil

Editor THE AUTOMOBILE—I notice that in the racing events both here and abroad the cars use castor oil as a motor lubricant. What advantages, other than less smoke, has this oil?

Leesburg, Fla. W. H. HOWELL.

—Castor oil has a greater viscosity than any other oil, used for motor lubrication, at the high temperatures experienced in racing motors. Therefore it helps to prevent the passage of the gases past the piston and the flow of the oil up into the combustion chamber, where it would burn and cause smoke. Since very little of the castor oil makes its way up to the combustion chamber, there is very little that is burned, but most of it is used for lubrication with the secondary advantage that much less oil is necessary.

It is not advisable to use this oil in everyday work, however, because it causes a heavy carbon deposit.

According to Professor F. Bendemann, in reviewing the

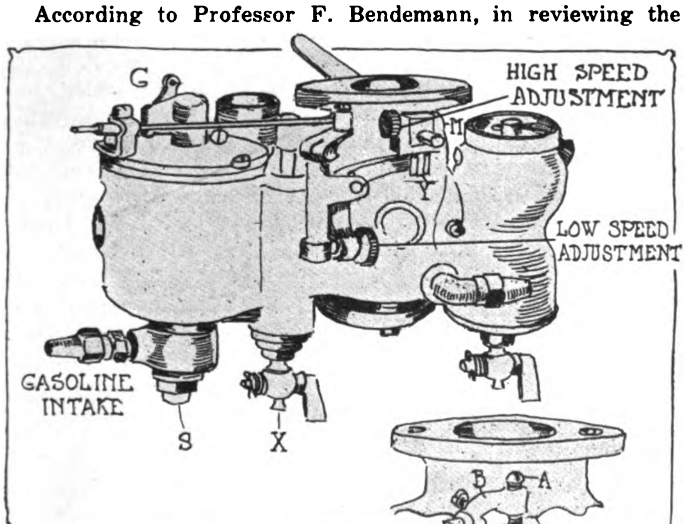

Fig. 2—New Rayfield G carbureter, showing adjustments

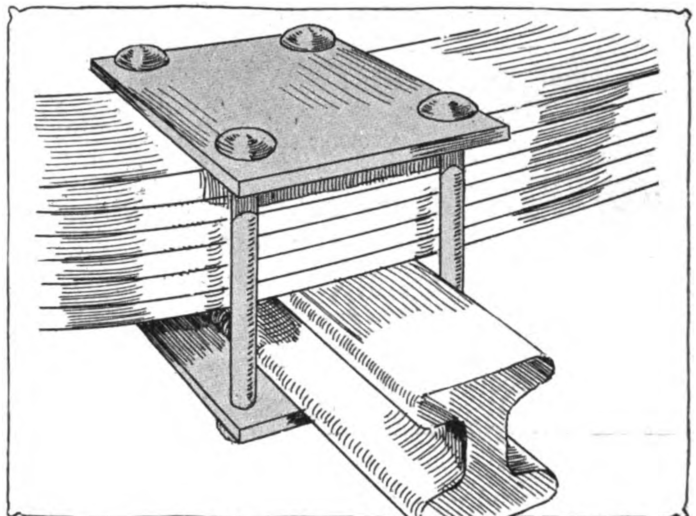

Fig. 3—Simple substitute for broken spring clip

progress in motor construction by the German builders, "at high temperatures castor oil retains its viscocity and lubricating properties considerably better than good mineral oil, as shown by the tests summarized in the appended table:

	Minimum Heat Units per kilogram	Viscosity in Engler Degrees at temperatures centigrade 60 deg.	100 deg.	120 deg.
Mineral oil, No. 1	10,116	3.37	1.65	1.41
Mineral oil, No. 2	10,080	2.75	1.46	1.20
Castor oil	8,298	10.72	2.72	1.95

"Castor oil is therefore still indispensable for air-cooled motors, but for the water-cooled motors at the contest one or the other of the two mineral oils referred to in the table was always sufficient."

Substitute for Broken Spring Clip

Editor THE AUTOMOBILE—A simple method of mending a broken spring clip is shown in Fig. 3, and as it saved me from being held up a long time on the road it is possible that it will be of service to some other motorists.

While touring in New England recently I noticed that the car developed a tendency to run to one side of the road, and finally it got so bad that I stopped to examine. I found that the right spring bolts holding the clip had given away and allowed the axle to slip back several inches.

There was a small village not far away and I drove the car to it slowly, and I had a blacksmith take two flat pieces of iron 1-4 inch in thickness and about 3 inches square and drill a 1-4-inch hole in each corner. Then I got four 1-4-inch carriage bolts about 8 inches long and improvised the spring clip shown.

Determination of Car's Age for Insurance

Editor THE AUTOMOBILE:—As the insurance rates on automobiles rise with the age of the car, when is a 1914 car purchased in July one year old, if the makers announce their 1915 model in August? What is the practice in other cities in this respect? It seems to me, that for insurance purposes, that a car's age should date from the time it is delivered to its original purchaser. The improvements on the present standardized automobile are seldom enough to make any material difference in the risk.

Pittsburgh, Pa. MURRAY FAHNESTOCK.

—A 1914 car is one year old from the date of purchase, but a 1915 car purchased in 1914 is given a lower rate the following year than if it had been a 1914 car.

Take for example a 1913 $2,000 car purchased in July, 1913, then the premium for insurance against fire and theft would be 2 per cent. the first year. The following year this

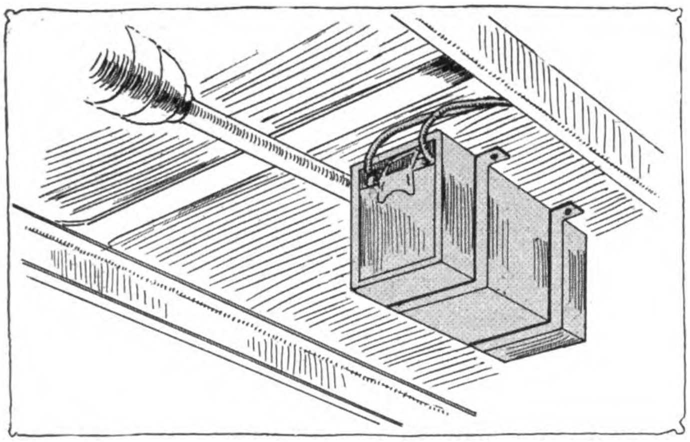

Fig. 4—Method of suspending battery from tonneau floor

car would be insured for 80 per cent. of its purchase price, or $1,600, and the rate would be increased to 2.75 per cent.

But if this car had been a 1914 car and had been purchased in July, 1913, although the premium the first year would have been the same as before, the second year the rate would have remained at 2 per cent. of $1,600, instead of rising to 2.75. In other words, the payment on the 1914 car for the second year would be two-hundredths of $1,600, or $32, while the premium on the 1913 machine would be two and seventy-five one-hundredths or $44. These rules apply to the principal companies all over the country.

Peculiar Play in Steering Gear

Editor THE AUTOMOBILE:—Will you please tell me in your next issue how to take up the play in the steering gear on a 1911 Model 30 Oakland. It is not in the steering knuckles or the drag link nor is it in the gear housing. Can it be taken up?

Isanti, Minn. EDWIN BOSTROM.

—It may be that the tie rod pins are loose, that the wheel bearings are worn or that the steering arm attached to the shaft running from the steering gear housing is loose. This shaft is squared and the arm is clamped in place over it. If the arm is merely loose, you should be able to tighten it by turning up on the nut, but if the play is very great a new part may be necessary.

Data on Design of Small Motor

Editor THE AUTOMOBILE:—I am designing a small gasoline engine, air-cooled, two-cylinder, vertical four-cycle, with 3-inch bore and stroke, to run at about 2,000 revolutions per minute.

1—What compression would it be best to figure on getting?

2—What size should the bearings on the crank and camshafts be, both diameter and length? Would three bearings on each be best? Would first-class babbitt metal be satisfactory?

3—What kind of steel is it best to use in the cams? How are they fastened to the camshaft and can they be fastened so as to be adjusted to different timing?

4—Would you advise roller or flat-ended push-rods?

5—What size and of what steel should the valve stems be with 1.5-inch valves?

6—Would the fact that the explosions occur irregularly, that is with intervals of 180 degrees and then 540 degrees, be objectionable?

7—Do you think that provision for cooling the lubricating oil would be of value?

Glen Ridge, N. J. PERCY S. WILSON.

—1—Make the compression 40 pounds.

2—Three bearings would be better than two for a motor of this speed. Make the crankshaft bearings 1.25 inches in diameter and 2 inches long, or longer if you do not have to consider the overall length of the motor. The camshaft should also have three bearings 2 inches long and 1 inch in diameter. Babbitt metal should be satisfactory.

3—Three and one-half per cent. nickel steel should be used. The cams should be pinned and keyed. It would be better, however, to make the cams and the camshaft in one piece as it is difficult to hold the cams securely. The timing can be varied by changing the meshing of the camshaft gear with respect to the crankshaft gear.

4—Use push-rods with roller ends.

5—The valves may be made of nickel, carbon or tungsten steel. Satisfactory valves should be obtained from any reputable manufacturer.

6—The irregular explosions offer a slight objection but it is not serious. Many motors of this type have been built in the past. It is better to do this than to have both pistons on the same crank throw, which would be required if the explosions occurred at equal intervals.

7—The operation of the motor would be slightly improved by cooling the lubricating oil.

Why Spacers Are Used in Annular Bearings

Editor THE AUTOMOBILE:—Why is it that spacers are placed between the balls in an annular ball bearing, but not in a cup and cone type? I should think it would make a stronger bearing if the race were completely filled with balls.

Los Angeles, Cal. J. W. BAER.

—The reason for this is simple. It is impossible to insert more balls in the annular type without cutting away a piece on one side of one race, thereby weakening the construction.

The method of inserting the balls is shown in Fig. 5, where it will be noted that the inner and outer members are placed eccentrically and the balls inserted, and then the balls are kept equal distances apart by spacers.

If a full race of balls is used, however, a notch for inserting the balls must be made and while a piece is put in to fill up this opening it is a source of weakness.

Place Battery Under Floor Boards

Editor THE AUTOMOBILE—I have an S. G. V. 1910 model and would like some advice as to the best location for a storage battery for an electric horn. The running boards are not available because a large tool box is carried on one side and the spare tires are on the other. Nor do I see how it can be placed under the seats because the gasoline tank is under the front one and the back one is too shallow.

New York City. R. P. W.

—The only solution seems to be to suspend it under the floorboards of the tonneau, as indicated in Fig. 4. Have a wooden box made just large enough to contain the battery and then have a blacksmith bend up two strips of iron to go around the container and bolt to the floor. The iron may by any convenient section, such as 1-8 inch by 1 inch. Have the bands made a little small so that they will fit snugly.

The battery may be held from slipping out of the open end by barring the opening by means of a bolt. If the closed end of the battery box is placed forward sufficient protection against mud, dust and grease will be afforded.

Weights of Pierce-Arrow Cars

Editor THE AUTOMOBILE:—In your issue of July 23 you gave a table of comparative weights of the Pierce, Packard and Peerless cars, in answer to a correspondent's inquiry. The correspondent, however, asked for the weights of these cars with the tanks empty, we presume he means without water in the radiator and without gasoline in the tank. These weights are at variance with our figures. The 38 horsepower is the most out. The weight of our 38-horsepower 1915 model is 4,263 pounds, the 48-horsepower is 5,050 pounds and the 66-horsepower is 5,450 pounds. These weights are for cars fully equipped with gasoline tank and radiator full, and also include two spare rims on the running board, four shock absorbers, a full set of tools with spare cans of oil and grease, one man top and glass front. The 38-horsepower is our five-passenger model and the 48- and 66-horsepower are our seven-passenger models. The weights of these cars fully equipped but without water and gasoline are:

38-horsepower, 4,057 pounds.
48-horsepower, 4,776 pounds
66-horsepower, 5,171 pounds.

We, as a rule, do not care to give the weights of our cars for the simple reason that our customer is apt to compare these weights with those given by other manufacturers and these weights may not include such equipment as we supply and may be without water and gasoline. Then again it must be remembered that our gasoline tanks are larger than some of our competitors, our 38-horsepower carries 26 gallons and the 48- and 66-horsepower carry 32 gallons.

These weights often show up to disadvantage and we think that in comparisons of this kind every feature should be the same in both cases, otherwise these comparisons are of no value.

Buffalo, N. Y. D. FERGUSON,
Mechanical Engineer Pierce-Arrow Motor Car Company.

The Chemistry of Combustion

Editor THE AUTOMOBILE—1—Will you please explain the chemical action that takes place in an automobile motor when the spark ignites the charge. Kindly use simple language as I am not a chemist.

2—Also state what effect the presence of moisture has on this action.

St. Paul, Minn. R. J. FOWLER.

—1—Assuming a perfect mixture, when combustion takes place when the spark occurs what actually happens is that the carbon and hydrogen, the elements in the gasoline, are reacted upon by the oxygen in the air in the cylinder, with the result that part of the oxygen combines with all of the hydrogen to form water and the rest of the oxygen combines with the carbon to form carbon dioxide. Directly after combustion the temperature of the gases is so high that the water is in the form of steam, but by the time it passes out of the exhaust pipe into the atmosphere it is merely vapor in the exhaust products. The nitrogen in the air remains neutral, that is, it is not affected by the combustion, but is merely heated up.

Gasoline is a combination of several oils forming a series that has the general chemical formula C_nH_{2n+2}, but for simplicity it will be assumed that gasoline is composed entirely of hexane, which contains 6 atoms of carbon combined with 14 atoms of hydrogen; this is expressed by the simple formula, C_6H_{14}.

Then combustion may be represented by the following equation:

$$\begin{array}{ccc} \text{Gasoline} + \text{Air*} & = & \text{Water} + \text{Carbon dioxide} \\ C_6H_{14} + O_2 & & H_2O + \quad CO_2 \end{array}$$

*Only one-fifth of the air is oxygen, the remaining four-fifths consisting of nitrogen and other inert gases, but these may be disregarded as they have no effect on the chemical action.

The above equation only holds good providing the mixture is perfectly proportioned and absolutely homogeneous. If there is too little air the combustion will not be complete and the result will be that there will not be enough oxygen to completely burn the carbon or the hydrogen in the gasoline. If there is just a little air lacking the result will be that there will not be enough atoms of oxygen to combine with all the carbon atoms to make carbon dioxide, CO_2 and therefore some of the molecules will have an atom of oxygen missing, that is, CO or carbon monoxide will be formed. With still less air it might happen that some of the atoms of the carbon in the gasoline could not find any oxygen to unite with, with the result that they will remain as carbon, and it is these small particles of carbon that indicate too rich a mixture by turning the exhaust into black smoke.

Too little air might leave some of the hydrogen atoms in the gasoline without any oxygen to combine with, and therefore some free hydrogen might be found in the exhaust.

With too much air there would be some free oxygen in the exhaust.

These remarks are assuming that the gasoline is perfectly vaporized and that the mixture is homogeneous. It is easily seen, however, that part of the charge might be too rich and another part weak, with the result that all the exhaust products mentioned will be found in the exhaust gases at the same time.

Suppose that the gasoline did not vaporize readily. Then part of the fuel would be carried into the cylinders in small globules. In the vicinity of these globules the mixture would be very rich, while some place else it might be weak.

2—The addition of water to the charge has no effect unless sufficient is added to absorb an appreciable amount of heat. When combustion takes place the water is turned into steam, and then as the temperature rises the steam is broken up into its constituent elements, hydrogen and oxygen, and a certain amount of heat is absorbed by these gases when this change takes place. Then as the temperature drops the hydrogen and the oxygen unite again to form water, and the same amount of heat is given off, so that the change does not affect the amount of heat produced nor does it change any of the gases.

Oil Trouble Caused by Wear

Editor THE AUTOMOBILE:—I have a 1914 Ford to repair and the front cylinder gets too much oil. It works all right when it has a clean plug, but after running about 100 or 150 miles, it misses. Can you give me some idea as to what the cause of the oily cylinder is?

Bath, Mich. ALBERT DETLUFF.

—The trouble is undoubtedly due to a worn cylinder piston or rings or to the openings in the three rings being in alignment. An inspection of this cylinder should show where the trouble is and if the piston or rings are worn they should be replaced.

The missing, of course, is due to the plug becoming fouled with oil.

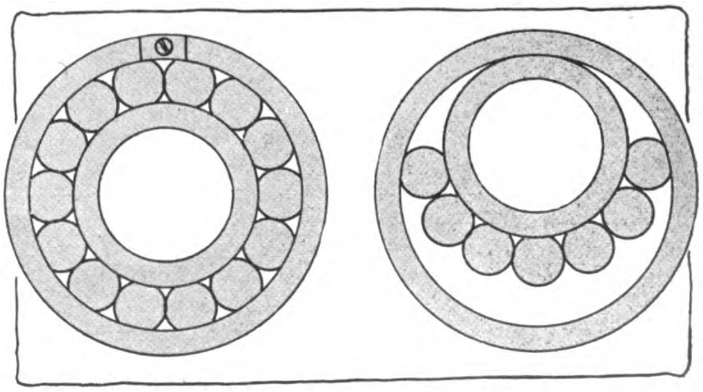

Fig. 5—Two types of annular ball bearings to show method of assembly. At the left is a full race and in order to insert the balls a part of the outer race is removable. If the races are made solid, then fewer balls must be used so that they can be inserted by placing them eccentrically, as at the right

The Engineering Digest

Design Features of Single-Valve Gnome Motor in Which Speed and Power Are Regulated Through Exhaust

CRANKCASE USED AS RESERVOIR FOR RICH, INEXPLOSIVE FUEL VAPOR CONSTANTLY RENEWED

SINCE it was found that the type of motor developed by the German Daimler company for aviation purposes (features of which were described in THE AUTOMOBILE of October 16 and 23, 1913) was also used in the Mercedes racing cars which carried away the principal honors in the recent Grand Prize race in France, the new features of other aviation motors are being watched more closely in the automobile industry. Even the improvements found of value for the motors with revolving cylinders, though these are still uneconomical with fuel and oil, are looked into, so as to keep account of all constructive and operative possibilities of the internal combustion engine.

In this class the Gnôme has long stood pre-eminent by its performances, and a description of its latest model, the *monosoupape* or single-valve type, and the method for obtaining speed and power variations by varying the stroke of the exhaust valves, will therefore be found of general interest. The description is furnished by Karl Feederle and Friedrich Hansen, residents of London, who have had ample opportunity to become familiar with the *monosoupape* Gnôme and contend that theirs is the first exhaustive exposition of the important features in this motor.

Efforts to get away from inlet valves in the pistons and to effect the intake of a fresh charge at the end of the instroke of the piston, while maintaining the four-cycle principle, began with the makers of the Gnôme motors in 1911, but acceptable results were not accomplished till 1913, when the first usable *monosoupape* model was shown at the Paris aero-salon. It was next exhibited at the Olympia show in March of this year.

It is a true four-cycle motor, with the difference from the usual arrangements that the introduction of fresh gas at the inner dead center of the piston takes place in this way that the rarefied fresh air contained in the cylinder at that moment is mixed with an over-rich gasoline vapor mixture which enters through slits in the cylinder wall. All the functions are rounded up within four piston strokes.

Details of the Cycle

The working sequence is as follows: The large exhaust valve remains open for 90 degrees after the burnt gases have been expelled and during this period the piston makes one-half of its instroke, drawing fresh air through the exhaust valve and cooling the latter. The valve now closing, this air is rarefied until the piston reaches a point corresponding to 155 degrees from the upper dead center, where it passes a circle of 10 slits in the cylinder wall, each 25 millimeters long and 5 millimeters high. The over-rich vapor mixture now enters through these slits, raising the cylinder contents to atmospheric pressure and forming an explosive mixture. On the outstroke of the piston, the compression of this mixture naturally begins at the same point—now 25 degrees past inner dead center—and continues till the ignition is effected by the magneto, at any point from the outer dead center to 15 degrees before it, according to the speed of the motor. The exhaust is opened 60 degrees before inner center and the centrifugal action pushes the burnt gas out rapidly; 35 degrees further on in the course of the piston the slits come into action again and relieve whatever pressure may still be present by providing an exit to the crank chamber, whereafter the outstroke of the piston cleans the gases completely out.

The patent protection for this new construction of the Gnôme motor relates mainly to the feature that the fresh gas mixture entering through the slits is so rich that it cannot normally be ignited from the burnt gas which may have entered the crank-chamber, and it is noted that the amount of such hot gas at all events must be small because the exhaust valve is opened 35 degrees before the slits. A further precaution is that the cylinder in the vicinity of the slits is provided with larger cooling-fins than are customarily used at the inner or lower ends of cylinders. In addition, the sleeves which connect cylinders with the crankchamber —B in Fig. 2—are provided with projections which serve partly to guide the portions of the cylinders which are below

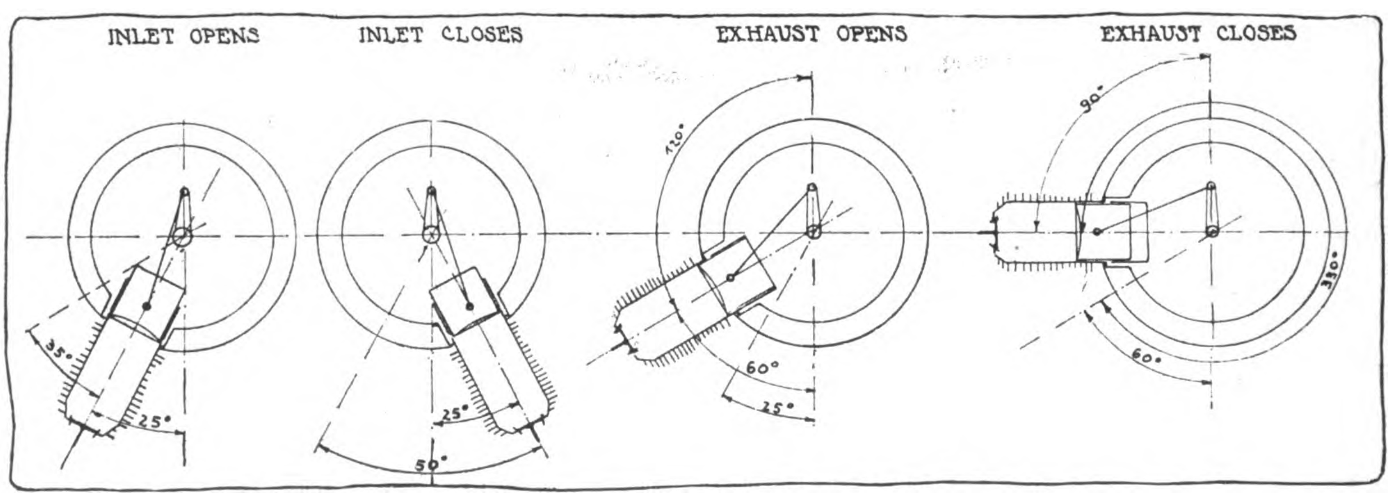

Fig. 1—Four-cycle valve-timing of new Gnome single-valve 100-hp. motor

the slits and also break up and cool the exhaust gas which may enter through the slits, so as to bring them below the temperature which might cause ignition of the fresh charge of vapor.

The arrangement of the cycle here described is illustrated in the four diagrams of Fig. 1.

Throttling by Exhaust Valve

The importance of keeping the fresh vapor so rich that it cannot be ignited made it inadvisable to attempt throttling by means of a butterfly valve acting upon a carbureter, as by this means the danger of getting too much air with a throttled charge would be obvious and the air might make the charge ignitable in the crankchamber. To control these proportions, the gasoline is taken to the motor through a small gear pump G actuated by gears from the motor, while the required air enters through the hollow propeller hub P of the motor, the stationary crankshaft remaining closed, in contrast with previous practice. In Fig. 2, which represents a section through the 100-horsepower Gnôme *monosoupape* with 9 cylinders and is drawn to scale, the channel F for the gasoline from the gear pump to the gasoline jet may be followed without difficulty. The jet J, which is nothing but a small perforated tube, lies before the middle of the intake port bored in continuation of the bore of the propeller hub and the current of air carries the constantly flowing fuel with it, filling the crankchamber with the desired over-rich and non-explosive mixture. No regulation, apart from the motor speed, is provided for reducing the fuel feed.

In order to be able to vary this speed and the power of the motor the stroke of the exhaust valves has been made variable. The construction serving this purpose is shown in Fig. 3, A, B and C, diagrammatically. A1A1 is the axis of the cylinder and of the exhaust valve; *a* is the rocker arm with fulcrum at *b*, and *c* indicates the position of the rocker arm when the exhaust valve is closed; *d* is the actuating-rod and *e* the guide for the tappet-rod *f*; *l* a ring which is turnable in the valve gear casing of the motor; *g* a small lug on this ring carrying pivotally the roller r_2 and the sliding-piece *h* upon which the roller r_1 of the tappet rod runs; *n* is the cam by which the valve is controlled. The ring *l* can be turned by means of a rod *z*, the latter

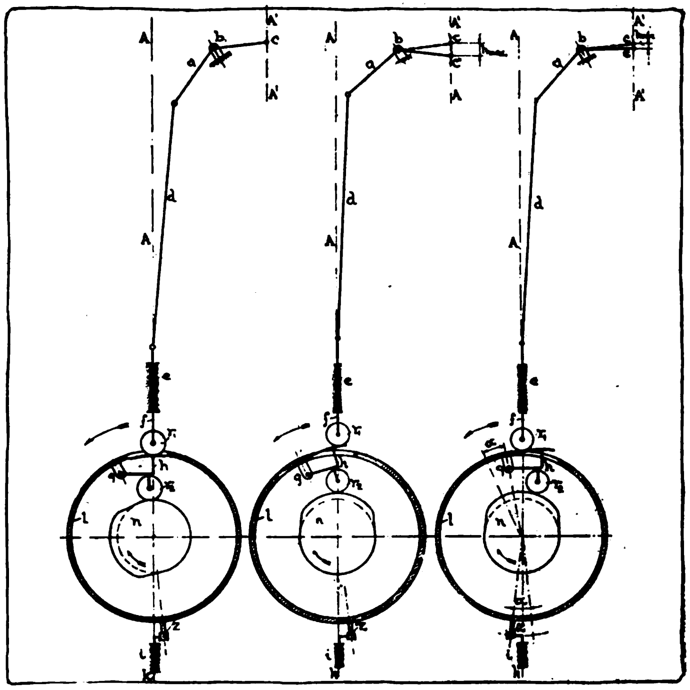

Fig. 3, A. B and C—Diagrams of variable-lever-arm system for operating exhaust valves

being first turned by the rod *k* which is mounted in the bearing sleeve *i*.

Fig. 3A shows the position of this mechanism with the valve closed, Fig. 3B with the valve opened to its maximum and Fig. 3C the same position as Fig. 3B, only with the ring *l* so turned that the valve opening is at minimum. The variation in the valve lift, as will be seen, is obtained by displacing the roller r_1 upon the sliding piece *h* with relation to roller r_2, whereby the lever arm by which the cam acts upon the tappet roller is lengthened or shortened.

Details of this mechanism can be followed in Fig. 2. Within the stationary crankshaft there is mounted a spindle S which at one end carries a triple-threaded screw T and at the other end a sliding piece U serving to turn a lever V attached to it and from the outer end of the latter extends a rod W which passes through the assembling-flange of the crankcase between two cylinders and serves to turn another lever Y to and fro, thereby turning the ring *l* as above referred to. The spindle in the crankshaft is actuated either directly by a handwheel or, as shown in Fig 2, by a pulley operated by cables. The longitudinal movement of the spindle amounts to 20 millimeters and corresponds to a half turn of the pulley.

In practice this arrangement for throttling on the exhaust has proved extraordinarily reliable and it is possible by means of it to vary the motor speed from 300 to 1,250 revolutions.

The advantages of the construction over the prior Gnôme construction consist first in dispensing with the automatic inlet valves in the pistons, so that these now can be made much lighter, and secondly in the reduced number of moved parts—one inlet valve in the motor taking the place of the many—by which the reliability of the motor has been much enhanced. It is also contended that the oil consumption has been reduced but the

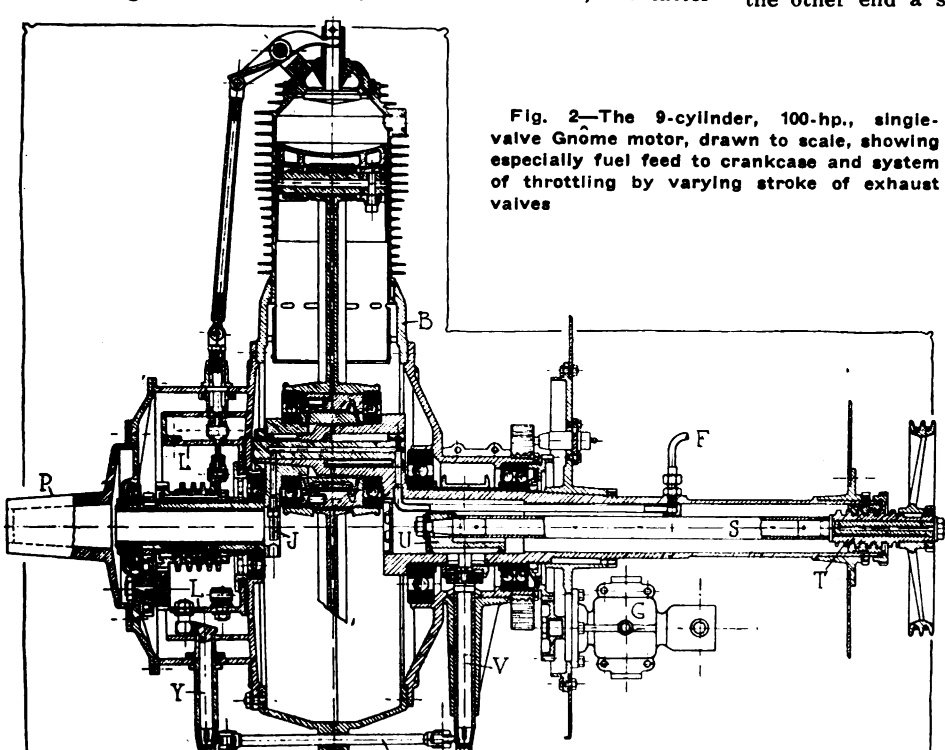

Fig. 2—The 9-cylinder, 100-hp., single-valve Gnôme motor, drawn to scale, showing especially fuel feed to crankcase and system of throttling by varying stroke of exhaust valves

writers have made the experience that considerable quantities of oil are still thrown into the cylinders through the intake slits and out through the exhaust valves. The fire risk is reduced because no opening in the motor exists on the back side toward the gasoline tank. It is a disadvantage, however, that despite all caution circumstances can arise under which explosions can take place in the crankchamber; even explosions strong enough to injure the motor. They can occur when for any reason the constant flow of gasoline is obstructed wholly or in part, as by clogging of the gasoline conduit, or when the gasoline in the tank is used up to the last drop. In these cases the gas already in the crankchamber becomes explosive because air alone continues to flow into it. Usually the result is only that the motor stops, but there is at any event an injurious effect upon pistons and joints.

The workmanship of the *monosoupape* model shows plainly the great experience gained at the Gnôme works. Some of the measurements are therefore interesting. The cylinder walls, turned from a good cast steel, are 2 millimeters thick. The crankcase is a very clean-lined sheet steel stamping made in two halves with turned-out bays for the cylinders. When the crankcase is assembled the cylinders are wedged into these cut-outs and keyed against turning. The joints with the case are of course outside of the slits in the cylinder walls, and farther inward the cylinders are aligned by means of the before-mentioned projections or teeth upon the metal of the casing. The exhaust valve is 50 millimeters in diameter, its stem 14 millimeters. The valve springs are of 3-millimeter steel wire bent to hairpin form and coiled with 2 1-2 turns. The maximum stroke of the exhaust valves is 10 millimeters and the minimum 3 millimeters. The valve seats, screwthreaded, and the valve guides, formed as simple two-armed yokes, are made very strong and in one piece with the fulcrum piece for the rocker arms. Bearings and lubrication are as in earlier models. The *monosoupape* is made in two sizes, one with 7 cylinders of 110 millimeter bore and 150 millimeter stroke giving 80 horsepowers at 1,200 revolutions per minute, and another with 9 cylinders of the same dimensions giving 100 horsepowers.—From *Der Motorwagen*, July 20.

Recent Court Decisions—Owner Held Liable

By George F. Kaiser

RESPONSIBILITY of a motorist for damages caused to his car depends on whether or not the driver was or was not engaged in his business at the time of the accident, says the Court.

A collision occurred between two automobiles, one of which was driven by a 19-year-old daughter of the owner. She usually drove the car, but at the time of the accident had turned the wheel over to a cousin at whose house she had been calling in company with her younger sister. The Court said it was a question whether or not she was engaged on her father's business at the time of the accident and answered the question affirmatively, saying that when a parent has an automobile and a child is authorized to use it at any time and the child injures a person, it is error to say that as a matter of law the parent is not liable. The Court also said that the fact that an agent when driving a car on his master's business permits a stranger to drive it, the master is not thereby relieved from liability.—*Kayser vs. Van Nest*, 146 *N. W.*, 1091.

Texas Repair Man's Lien

Texas Court holds automobile repair man has a lien for storage and repairs.

A car owner placed his car with a motor company for repairs, with the understanding that it was to be put in first class condition. A dispute arose as regards the bill and the owner, refusing to pay, the dealer advertised the car for sale. The owner then sued them for $1,000 damages to the car, $385 for loss of use of the same and asked that an injunction be granted restraining the sale. The owner claimed that it was agreed that $35 was to be paid by him to cover all charges for labor and materials. The defendant denied this agreement and claimed $73.17 was the reasonable value of the work and also asked payment at the rate of $5 per month for the period during which the owner refused to accept the car and pay the bill.

The repair man recovered judgment for the charges and for storage at the rate of $2.50 per month, the Court saying: "At common law warehousemen had a special lien on property stored with them for their proper charge in connection with the specific bailment and the right to retain possession until paid, and such lien and right were preserved by the revised Statutes of 1911, Act 5671, providing that nothing in Chap. 8 relating to liens of which such article is a part should impair or effect liens arising at common law or in equity and hence a company engaged in the business of repairing and storing automobiles is entitled both at common law and in equity to liens on a car for storage charges after the owner improperly refuses to pay for the repair and remove the car.—*Macolm vs. Sims Thompson Motor Car Co.*, 164 *S. W.* (*Tex.*) 924.

Suit of Newsboy's Father Reversed

Court holds that where a father sues a motorist to recover for money he has spent for hospital services, and to hire a physician to attend his son, who was run down and injured by an automobile, he is entitled only to recover the reasonable value.

A newsboy was run down and injured by an automobile. His father sued, as guardian, and recovered $750 for his injuries. He then started another action against the automobile owner, claiming $5,500; $5,000 for loss of services to the father, and $500 for expenses. The jury gave him a verdict for $500. When the motorist appealed, the case was reversed, because the court held that it was wrong to put in evidence all that the son earned as a newsboy, when part of his earnings consisted of tips, as tips were too indefinite to be properly computed.—*Forgeson vs. Hanford*, 139 *Pac.*

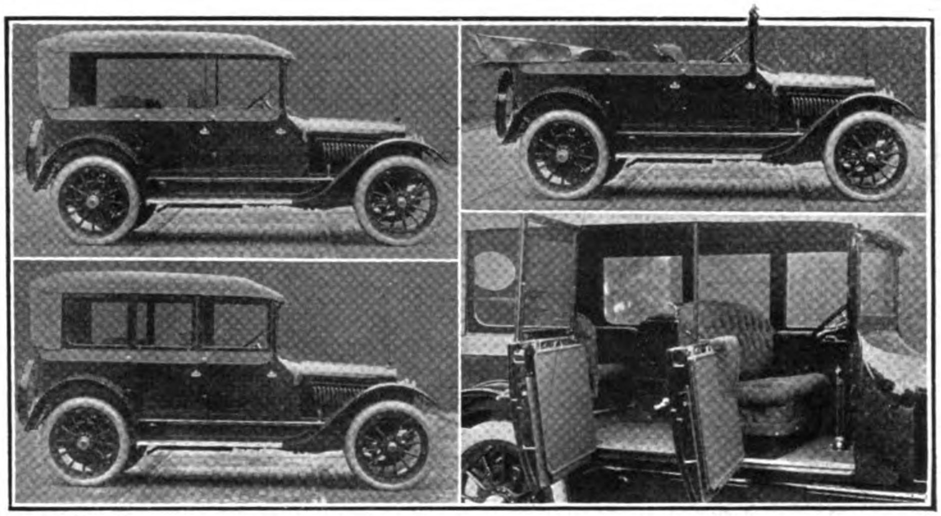
Motorist Not Liable

California Court says that it is the duty of foot pedestrians to look both ways before starting to cross a street, particularly when the street over which the pedestrian intends to cross is a busy thoroughfare in the heart of the business district of a great city and that the fact that a motorist violates a speed ordinance does not prevent the Court from finding the pedestrian guilty of contributory negligence and refusing to allow him to recover for his injuries.

This case was a suit for personal injuries caused by an automobile in Oakland, Cal. The chauffeur was found to have been guilty of negligence because he drove his car at a speed in excess of that allowed by the city ordinance and gave no warning on approaching the street crossing. The injured person sued both the chauffeur and the company by which he was employed. It was found that the chauffeur was not on the company's business, however, so he was held not to be liable and then the Court further finding that the pedestrian was guilty of contributory negligence absolved the company from liability and rendered judgment against the injured person.—*Davis vs. John Breuner Co. et al.*, 140 *Pac.* (*California*) 386.

Wide Doors in New Convertible Bodies

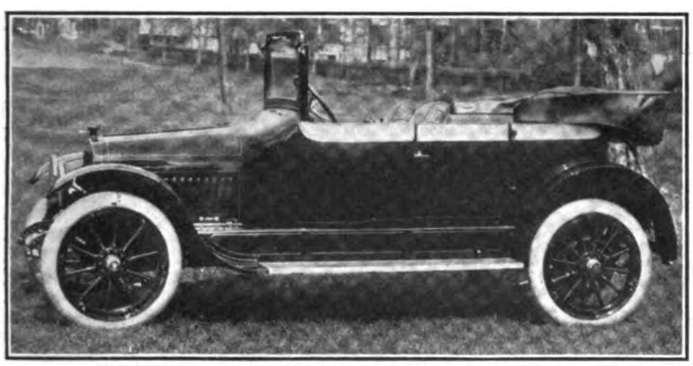
Springfield Company Has Three New Bodies—Sedan, Limousine and Runabout Types



Four views of new Springfield limousine type. Note three windows, instead of four

THREE new convertible bodies with exceptionally wide window spaces have recently been added by the Springfield Metal Body Co., Springfield, Mass. In the limousine and sedan types the window space has been divided into three panels, giving a better lookout and, since the doors are wider, easier entrance and egress. In addition a convertible runabout type, also with wide doors, is offered.

The new limousine is built with five and seven-passenger bodies and differs from former models in that the doors have been widened considerably, the front one now being 22 inches and the rear 27; in this way the window between the two doors in the older models has been eliminated. This change not only gives the passengers more room but it simplifies the raising or lowering of the sides. The door windows are on hinges and lay on the inside panel of the doors. They are covered by a pad of the same material as the upholstery, and in raising the sides it is merely necessary to swing these pads out of the way and pull up the windows. Only the rear windows are carried in a pocket on the back of the driver's seat, while in the old type the windows between the doors are also carried here. Thus it is seen that it is less trouble to put up the sides on this new body.



Sedan with top and sides down

The sedan type is similar to the limousine except that it has a single door 25 inches wide. There is an aisle between the front seats which are of the chair type. This model is designed with seating capacity for four or five people.

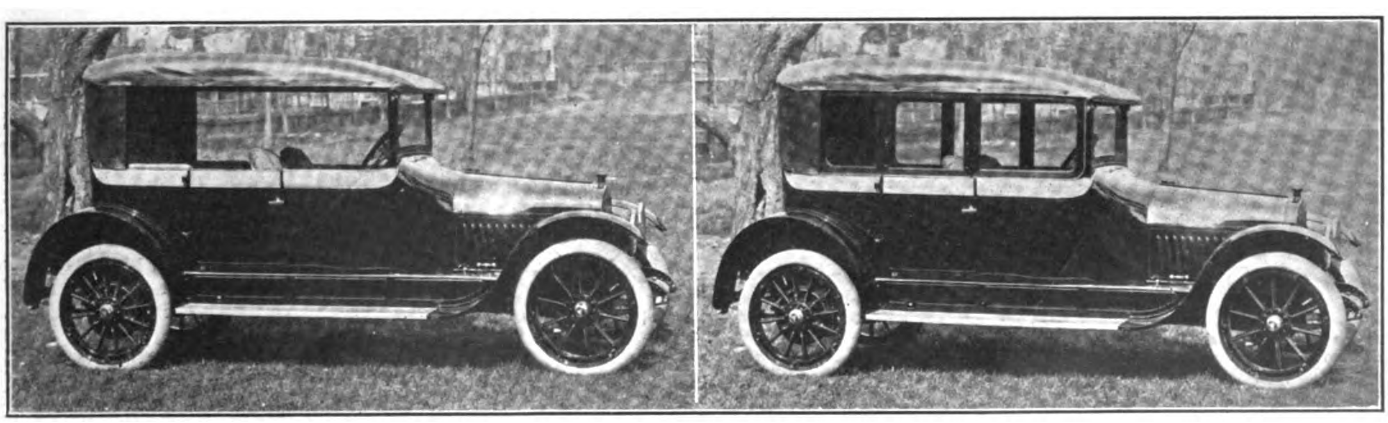
The runabout is made with either a two or three-passenger body.

The painting and the upholstery as well as details concerning the interior fittings are left to the individual taste of the purchaser. The upholstery material may be hand-buffed leather, broadcloth or motocloth.

The prices of the bodies mounted are: Runabout, $900; sedan, $900; five-passenger limousine, $1,300; seven-passenger limousine, $1,400.

The advantages of the convertible type of body are almost too well known to require enumeration. It does the work of two bodies, one of the closed and another of the open type, and further has the advantage of being able to change from one to the other in less than 5 minutes. In changeable weather this is of special advantage because one day it may be pleasant enough for the touring type of body while the following day it may be cold and inclement enough to make the closed type highly desirable.

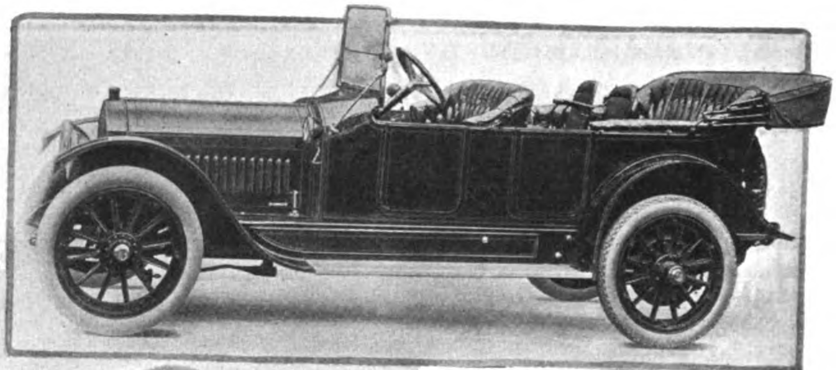
These bodies may be mounted on any standard chassis.

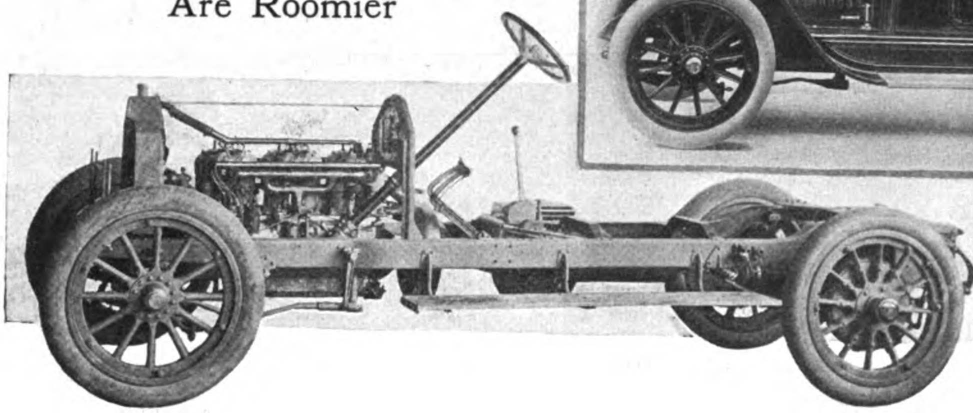


Left—Sedan with top raised. Right—Sedan fully inclosed

1915 Republic Is 2 Inches Lower

Clutch Has Springs Under Facing—Steel Timing Gears Used—Bodies Are Roomier





Above—1915 Republic six-cylinder, seven-passenger touring car for $2,950. Note new method of fastening windshield

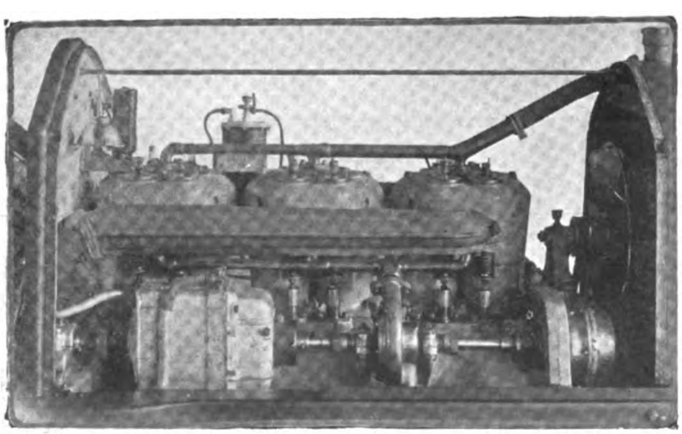
Left—Side elevation of six-cylinder chassis on which two, four and five-passenger bodies are mounted

MARKED body changes, a reconstructed clutch, steel timing gears and the introduction of the Stewart-Warner vacuum gravity gasoline feed are the changes in the Republic Six for 1915. The cowl has been lowered and lengthened, the distance between the dash and front seats increased 2 inches, the seats lowered 2 inches and the method of fastening the windshield has been improved, giving a longer, lower car than the preceding model. The price of the car remains the same at $2,950 for the two, four- and five-passenger bodies.

T-Head Six-Cylinder Motor

The chassis which carries all the body models made by the Republic Motor Car Co., of Hamilton, O., has a wheelbase of 133 inches. The power plant, which remains the same as in the 1914 model, is a six-cylinder 4.25 by 5-inch motor, rated by the manufacturer at 60 horsepower and having a formula rating of 43.5. It is of T-head design with the cylinders cast in pairs.

The cylinders are cast of close-grained gray iron and carry 2.25-inch interchangeable exhaust and intake valves. The pistons are of good proportions, measuring 5.5 inches in length. The connecting-rods are of I-beam section and are 11 inches in length. The crankshaft is carried on four main bearings, the front and center ones are 2.5 inches long and the rear which carries the strains imparted by the starting motor, which engages with the flywheel, is 3.5 inches long, providing a good margin of strength at this point. The crankshaft diameter is 2 inches.



Right side of six-cylinder motor 4.25 by 5 inches, used in the 1915 Republic. The manufacturer rates this motor at 60 horsepower. Its formula rating is 43.5. Note mounting to Delco generator on pump shaft

Two Camshafts Employed

There are two camshafts, each with the cams cut integrally on the shaft. The camshaft bearings are four in number and the diameter of the camshafts is 15-16 inch. The two center camshaft bearings and the rear bearing are 2 inches in length. The forward camshaft bearing which receives the thrust given by the timing gear in driving the shaft is made 2.75 inches in length. This year the timing gears are made of steel whereas in the 1914 model the gears were of cast iron.

Force-Feed Lubrication

The motor is oiled by a force-feed system. The oil is carried in a reservoir beneath the crankcase and is pumped from this by a gear pump which takes the oil through a sight feed on the dash and then forces it through an independent lead to each of the main bearings and by means of a hollow crankshaft to the lower connecting-rod bearings. From the latter point the oil is thrown to the cylinder walls.

Delco Lighting, Starting and Ignition

The electric equipment of the car consists in a Delco lighting, starting and ignition plant. The Delco system installed on this car has one special feature which distinguishes it from other Delco designs in that the starting drive and the generator drive are independent. The control is also the latest design, starting being accomplished by merely depressing a pedal. The Delco ignition system is a dual design. The running current is supplied by the generator and the battery supply for starting from the storage battery.

Stewart Gravity Feed System

The gasoline system is the Stewart-Warner vacuum gravity system. A 21-gallon gasoline tank is supported from the rear of the frame members. The system comprises a float tank attached to the dash of the car and two pipes, one of which runs from this tank to the carbureter and the other to the fuel tank. The suction of the motor draws the fuel first into the small dash tank from which it flows by gravity to the carbureter. It is claimed that this system does away with the disadvantages of a pressure feed and is still simple. A Rayfield carbureter is used.

The cooling of the motor is effected by a gear-driven centrifugal pump which forces the water through a cellular radiator and through the cylinder water jackets.

Springs Under Clutch Facing

The clutch which has been rebuilt this year is still of the cone type but instead of having cork inserts there are a series of flat springs placed beneath the leather. The springs are twelve in number equally spaced about the periphery of the cone. The operating mechanism of the clutch has not been altered. The pedal for the clutch also operates the service brake. Another pedal operates the emergency brake, thus permitting the operator to put on both sets of brakes and at the same time to keep both hands on the steering wheel. The gearset is the same as in the past, furnishing four forward speeds. The gears and shafts are of 3.5 per cent. nickel steel operating on Hess-Bright ball bearings.

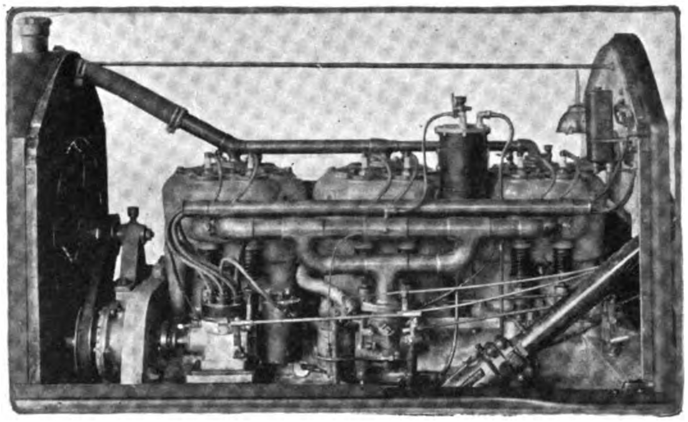
Hess-Bright Bearings Used

The driveshaft operates the bevel gear differential through a 3.5 per cent. nickel steel pinion. The axle is a floating design inclosed in a pressed steel housing and runs on Hess-Bright annular bearings. The shafts are vanadium steel and the gears are chrome vanadium. The front axle is a drop-forged I-beam and the running parts are carried on Hess-Bright ball bearings.

The chassis frame is of pressed steel channel, 5 inches in depth, and made up of 3-16 inch material with integral gusset plates to meet the strains of the rear spring suspension. It is narrowed at the front end to shorten the turning radius and has a dropped construction over the rear axle.

Left Drive and Center Control

The tread of the car is standard, and the wheels are 36 inches in diameter, taking 4.5-inch tires. The front springs are chrome vanadium, 2 by 38 inches. The rear springs are three-quarter elliptical 2.25 inches wide and 50 inches long. They are fitted with rebound straps. The brakes operate on drums bolted to the rear wheels and are 2.5 inches wide by 16 inches diameter. Left drive and center control is used. The steering wheel is 18 inches diameter.



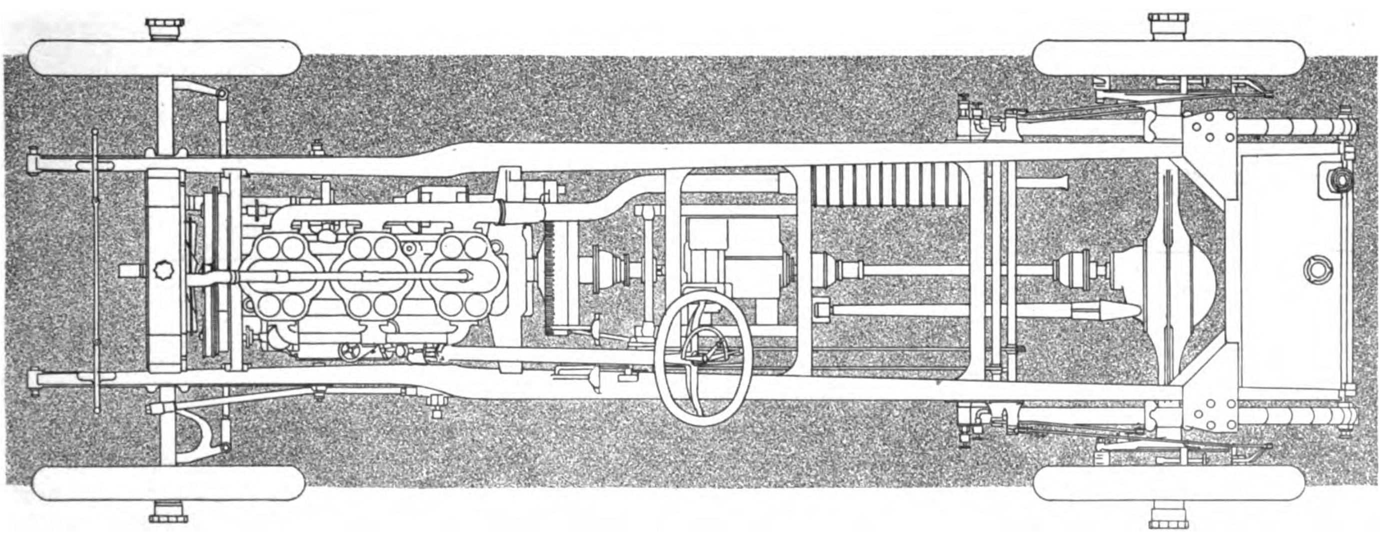
Left side of six-cylinder motor used in 1915 Republic, showing mounting of Rayfield carbureter, intake manifold and hot air intake for carbureter brought between front pairs of cylinders. Also note mounting of Delco ignition system. This is a dual design, the running current being supplied by the generator and the battery supply for starting being taken from the storage battery

New Company To Build Light Car for $800

PONTIAC, MICH., July 31—Men well known in the automobile trade all formerly connected with the Oakland Motor Car Co., are now organizing a new company which is to have a capital of not less than $300,000 and which is to build a light, popular-priced automobile, which it is said will cost between $800 and $900. The promoters are, former vice-president George E. Daniels; former assistant sales manager Howard Bauer; J. H. Newmark, former advertising manager; W. R. Williams and L. Eccleston. The concern will probably locate in Pontiac although this has not been definitely decided.

$825,394 in Packard Truck Sales in 4 Months

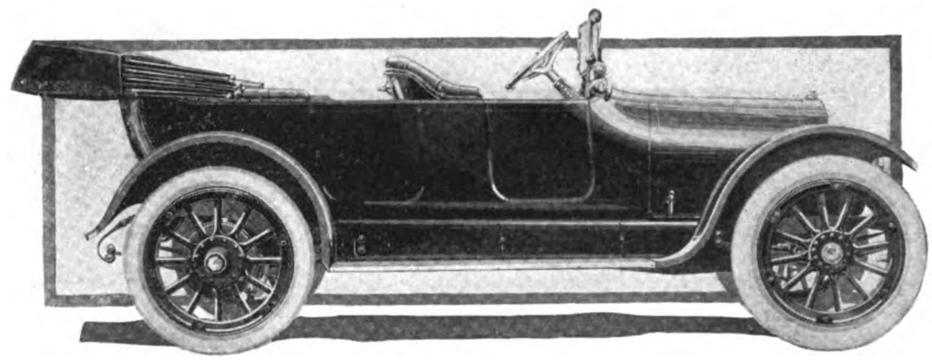
DETROIT, MICH., July 31—During the 4 months from March to June, 1914, the motor-truck business of the Packard Motor Car Co., Detroit, has been near 60 per cent. greater than during the corresponding period in 1913. During June the number of trucks sold represent a sum of $825,394, or $256,994 more than in June, 1913. "If the business continues that way," said one of the officials of the Packard company, "and we see no reason why there should be a slacking down, it will probably mean the biggest business year the Packard company has had in the sale of its trucks."



Plan view of Republic chassis, showing main gasoline tank at the rear from which fuel is led to the float tank attached to the dash of the car, whence it runs to the carbureter and motor by gravity. Note strong torsion rod from differential housing to cross-brace at rear of gearbox

New Streamline Overland Has Left Drive

Four Cylinder Chassis Continued Practically Unchanged—Reciprocating Parts Lighter—Many Minor Refinements



Overland four cylinder, five-passenger touring car for 1915. Note the streamline body with left drive. This car uses 34 by 4-inch tires and sells for $1,075

UNDER the name of Model 80, the 1915 Overland four-cylinder car is a continuation of the Model 79 introduced for 1914. The new car remains the same in all the elementary features and important dimensions as in 1914, but has been refined throughout to give a larger, roomier design of up-to-date appearance.

Graceful Streamline Body

The striking feature of the new model is the large, graceful streamline body with its left drive. This is the first year that the steering wheel has been mounted on the left in Overland cars. In shifting from right to left drive little change has been made in the chassis. In fact, the only alteration necessitated in the motor is the bending of the exhaust manifold closer to the cylinders.

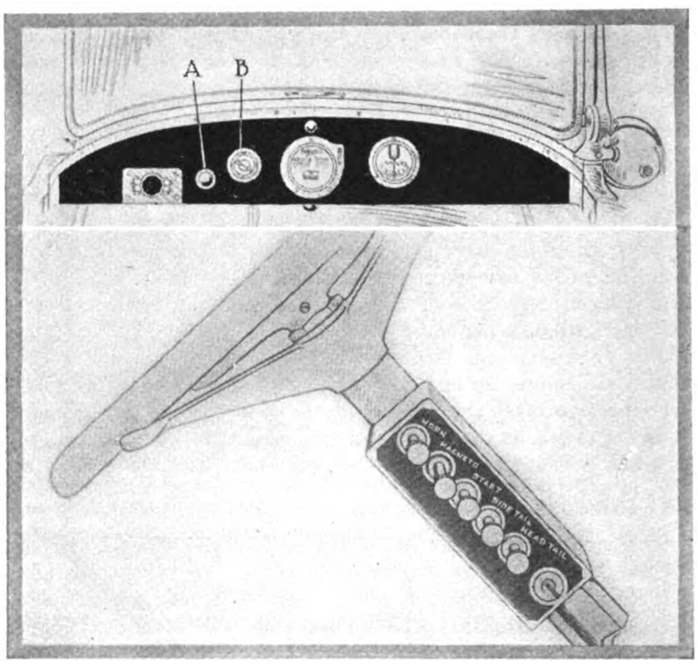
Improvement in Oiling System

The chassis remains practically the same as it was on the Model 79. The motor has not been altered, with the exception of a small improvement in the oiling system, which has been made to insure all cylinders securing an equal amount of oil on level roads and when ascending a steep grade. The change provided to accomplish this result is the moving of the oil feed to the forward end of the crankcase. The reciprocating parts have been lightened by making the webs in the pistons thinner than last year, and the piston rings are now balanced by having drilled holes which allow the gases to get behind the rings.

For easier assembly and to do away with metallic sounds, a union joint has been placed in the exhaust pipe just back of the motor. Ignition is now by Bosch high-tension magneto driven at crankshaft speed through a leather coupling. The carbureter is also improved by having a hot-air attachment for both the primary and auxiliary ports.

New Features of Control

In moving the steering gear to the left, the gear control is set farther forward from the front seat than it was in the previous model. Other features of the control have also been changed: A switch box is now attached to the right side of the steering column, 2 inches below the wheel. Through this keyboard the electric horn, lights and ignition are controlled without the effort of stooping forward to the instrument board. The starter button is also on this keyboard and must be pressed before the starter pedal. This arrangement has been made so that it is not possible for the driver to throw in the starter by accidentally stepping on the starting button. Pressing a button on the steering column operates a solenoid which unlocks the sliding gear. The current is connected when the armature shaft sliding gear meshes with the teeth of the flywheel gear.

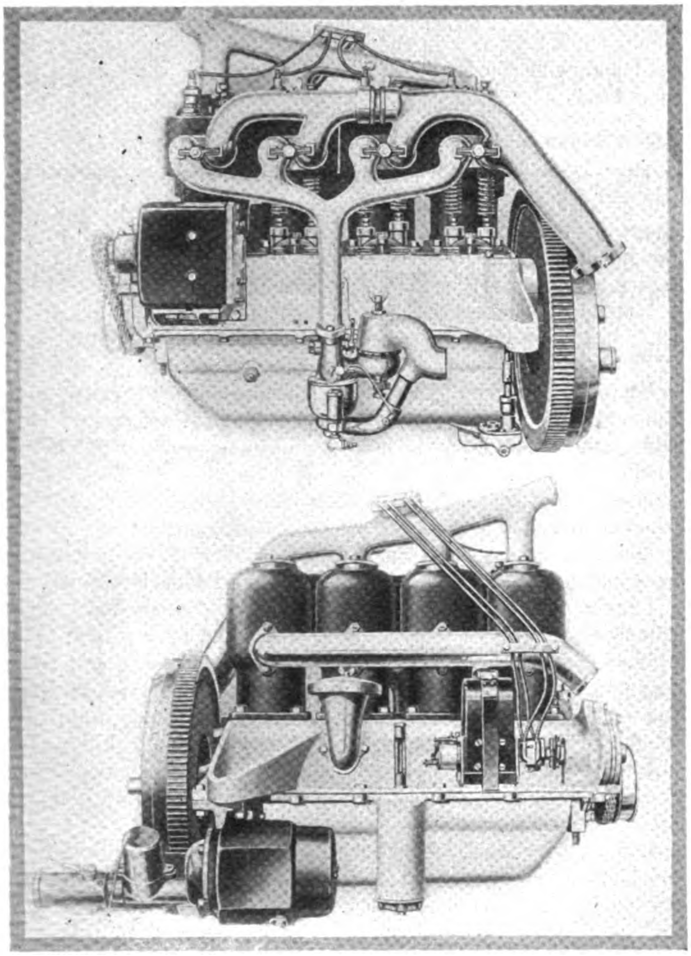


Above—Cowl board of 1915 Overland. A is the primer and B is the sight feed for the oil in which a small vertical wheel operated by the oil always shows how the oil is flowing when the motor is running. Below—Control switches mounted on steering column, forming a centralization of electrical control

There is a muffler cut-out on this model which can be operated by kicking a small lever. The accelerator is of new design and a side rest is provided for the foot to eliminate strain when driving for a long distance. The pedals on the coupé model are now adjustable. A new sight feed will be found in the layout of dash instruments. This is an ingenious device which has a small vertical wheel operated by the oil passing through the sight feed. When the oil clogs the feed so that the ordinary sight feed would not be visible, with this device it is still possible to see the revolving wheel and thereby follow the oil flow.

Body Has Been Greatly Enlarged

The body has been greatly enlarged and provides an exceptional amount of space both in the forward compartment and in the tonneau. Though the wheelbase remains at 114 inches, the space has been utilized better and larger seats and many other features of comfort included. The rear seat,



Above—Valve side of Overland four-cylinder motor for 1915. Note the unusually low mounting of new Schebler carbureter insuring proper feeding of fuel under all conditions. Lower—Exhaust side of 1915 Overland motor showing high-tension Bosch magneto driven through a flexible leather coupling, oil level indicator and location of starting motor. Note large water intake pipes for thermo-syphon cooling system, and also method of conducting wires from magneto to plugs.

for instance, is now 49 inches wide inside. The front seat is 40 inches wide, and the backs are 19.5 inches high in the rear and 17 inches in the front. The seats are 20 inches deep in the rear and 19 inches in front.

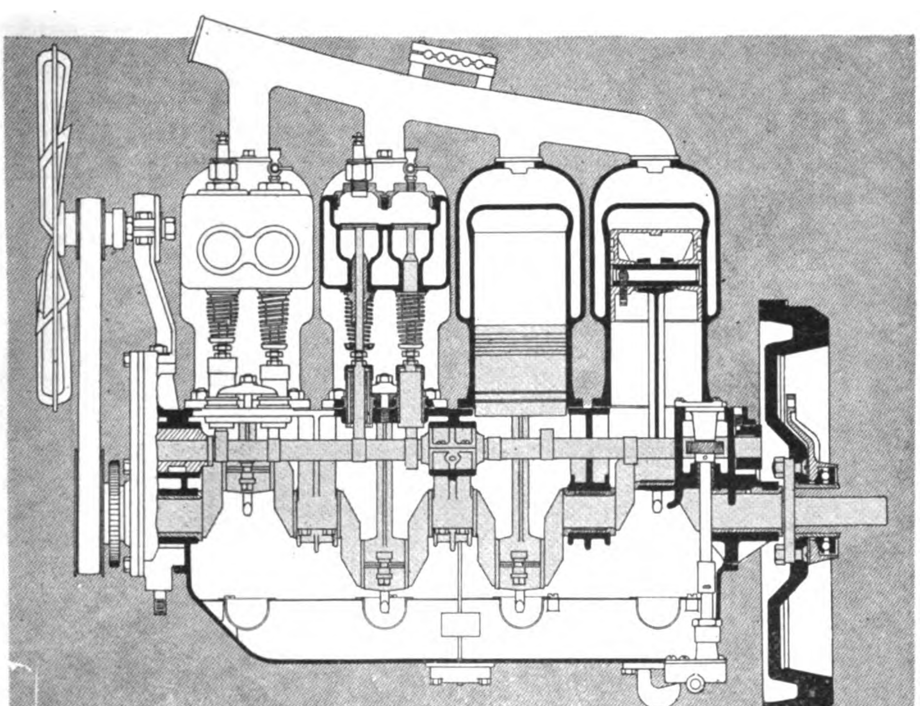
Curtains Stored in Front Seat Back

Many interior refinements are to be noted. There is a new top which has its storm curtains stored in a metal box directly behind the front seat, rendering it possible to put these curtains up without disturbing the passengers in the tonneau. Instead of the leather straps which ordinarily hold the folded-down top, the new Overland has a unique clamp which holds the top back securely and at the same time prevents all rattling. Leather pockets are now provided in all the doors and in addition these doors are hung on concealed hinges with inside-operated latches placed so as to make it impossible to catch in the clothes of a passenger leaving the car.

The front seat has a division between the driver and the front passenger, whereas in the Model 79 the front seat was all in one. The windshield is now built directly on the top of the cowl and provides rain vision and ventilating facilities, at the same time being waterproof. The fittings on this windshield are smaller than on the previous design. The folding windshield brackets are now vertical in place of the sloping brackets used before. These changes are in line with the development of the streamline form of car used this season. The radiator is molded into the body curve and the engine hood slopes gradually to the new form of cowl dash. The body line then sweeps without abruptness to the full curved tonneau back, giving a well-rounded design, which follows the modern trend in body design without offering anything of a radical departure from standard practice.

Body Is 3.25 Inches Lower

The floating axle is continued and the brakes are unchanged, but a new design of front axle is employed, which, together with the body frame, brings the body 3.25 inches closer to the ground. The rear springs are now underslung and both front and rear are the same shape as in the Model 79. The rear springs are longer than they were, being now 48 by 2 inches whereas they were formerly 42 by 1.75 inches. On the Model 80 the frame has been given a drop of 3.25 inches. It is much stronger, having a channel section 3-16 inch deeper, 1-4 inch wider and 1-64 inches thinner in the webb than the previous model. The wheel size of the car has also been increased and now 34 by 4-inch tires are used in place of the 33 by 4.

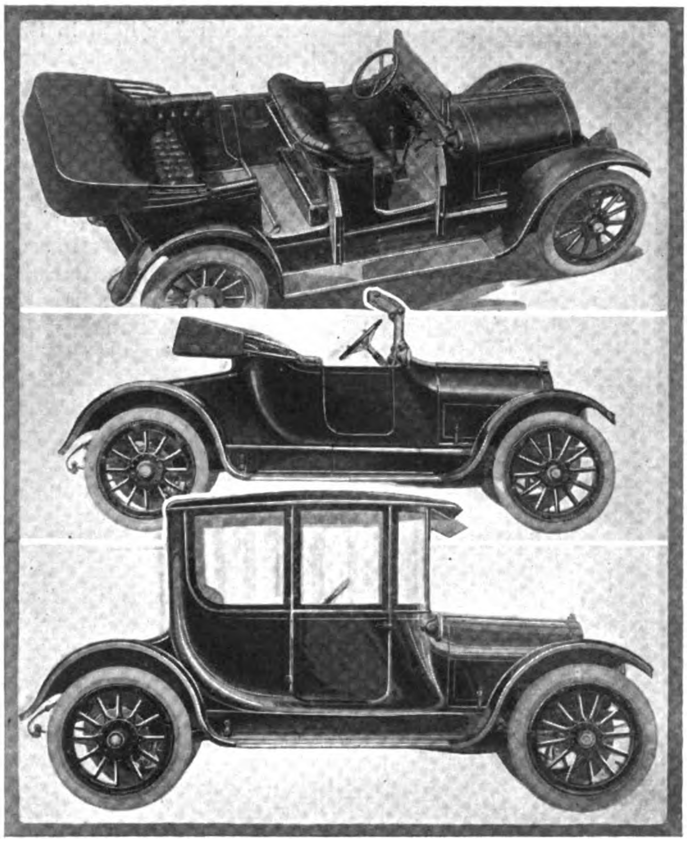


Part sectional view of 1915 Overland motor showing mounting of spark plugs directly over intake valves and priming cups directly over exhaust valves

Electrical System Slightly Changed

The starting and lighting system has been re-designed in many particulars: while in the previous model the starter shaft was connected with the crankshaft by silent chain, it now meshes directly with a gear wheel on the flywheel. With the new starting system the Overland engineers claim that the motor can be cranked under ordinary circumstances at from 190 to 200 revolutions per minute. The electric generator, which is a separate unit, is mounted on the left side of the motor and is driven by silent chain. The features of this system will be described later.

The price of the standard touring car model, seating five passengers, is $1,075. The two-passenger roadster



Top—Body view of 1915 Overland five-passenger touring car, showing arrangement of instruments on cowl board, centralizing control on steering column, left drive, hand control quadrant set forward for easy egress, pockets in doors and container for side curtains behind front seat. Middle—Two-passenger roadster design fitted on four-cylinder chassis. Bottom—Four-passenger coupé

is offered at $1,050, while the four-passenger coupé, which comes equipped with 35 by 4.5 non-skid tires, is listed at $1,600. These prices include full equipment, and are the same for the touring car, $25 less for the roadster and $50 more for the coupé than they were for the previous model.

Motor Develops 35 Horsepower

The Overland power plant has its four cylinders cast singly and set 9-16 inch off center. The cylinders are L head shape, carrying the valves and manifold all on the left side of the motor. The bore is 4.125 and the stroke 4 5 inches, developing, according to the Overland engineers, 35 horsepower on the brake at normal speed. The pistons have two rings, each of which is a double design providing compression and lightness in small space. There are two oil grooves below the wristpin. The wristpin is held solidly in the piston boss and is of hollow design. The wristpin bearing is lined with bronze. The connecting-rods are I-beam section and are connected to the crankshaft at the crank bearing by two bolts.

Five-Bearing Crankshaft

The crankshaft is a carbon steel drop forging having five main bearings. The length of the main bearings are respectively 3.5 inches and 2.125 inches. The rear bearing has the first mentioned length, having to carry the flywheel and to take the thrust of the starting motor. The other four bearings are all the same length.

The camshaft is also a carbon steel drop forging and is carried on three bearings. The length of the rear end bearing is 2 inches, the front bearing is 2.25 inches and the center bearing 2.75 inches. The diameter of the camshaft is .9375 inch. The cams are integral with the camshaft and act directly on the push-rods of the valves.

The tappets are held in long guides which are designed to prevent oil from leaking past the bushings. The valve springs are held in cup-shaped disks and the valves are also provided with bushings at the point where they enter the cylinder.

Spark Plugs Over Intake Valves

The spark plugs are placed directly over the intake valves and priming cups are placed over the exhaust valves. The shape of the ports and the method of extending the water jackets around them are shown in the sectional view of the motor. Valve opening diameter 1.625 inches, intake lift 11-32, exhaust 13-32 inches.

Cooling By Thermo-Syphon

Cooling is accomplished by a thermo-syphon system and the water jackets, together with the water intakes and outlets, have been kept large with a minimum amount of curvature to meet the requirements of this system. Cooling is further aided by a six-blade fan driven by a belt. The fan bracket is bolted to the crankcase. A change has been made here for this season in that the fan now runs on ball bearings in place of the plain bearings used in Model 79.

Lubrication of the motor is secured by the constant level splash system, in which the oil is circulated by a pump. The oil reservoir is in the bottom half of the crankcase and from this point the oil is taken by a gear pump and forced through the new sight feed on the dash. The oil lead runs along the length of the crankcase and keeps the splash troughs constantly full. The scoops on the bottoms of the connecting-rods keep the bottom of the motor filled with a thick oil mist.

Current for ignition is supplied by the Bosch magneto mounted on a bracket at the right front end of the motor. The drive is through a leather coupling and the leads are carried in fiber blocks which are held on the water intake and outlet pipes.

Bosch Single Ignition Used

At the speed at which the motor cranks the engine, there is no need of an auxiliary system for starting and hence the Bosch single ignition has been adopted. The generator which supplies the current for the storage battery is mounted on the left side of the motor at the front end and is driven by silent chain off the crankshaft. The generator cuts in at a car speed of 7 miles an hour and reaches its maximum output of 14 amperes at 18 miles per hour. Regulation of the current is effected by a compound shunt winding in the armature of the generator. The cranking motor is series wound, operating at 6 volts through a gear which meshes directly with the flywheel.

Double Heating of Carbureter Intake

The gasoline system is by gravity. On the touring cars the capacity of the tanks is 15 gallons and on the roadster 30 gallons. The carbureter is the latest design of Schebler Model R, provided with a double heated air intake which takes care of both the primary and auxiliary air supplies. This arrangement is shown in the side view of the motor. The carbureter primer has been moved from the steering column to the cowl board and by its use a rich mixture can be provided for starting. No amount of gradient which will ordinarily be found can affect the flow of gasoline to the carbureter, as it is hung exceptionally low. The straight part of the intake manifold extends vertically upward to some distance before it branches out in the balanced Y in passing to the cylinder ports.

New Gear Ratios Adopted

The clutch is a leather-faced cone provided with a brake to aid in gear shifting. This design has not been changed in any particular. The gearbox, while the same in nearly every particular, now has a different set of gear ratios and the countershaft has been made adjustable by the addition of two adjustment screws, one at either end. The gear ratios are now as follows: First—11 7-16 to 1; second—6 7-8 to 1; third—3 3-4 to 1; reverse—14 3-4 to 1.

With these ratios at 1,000 revolutions per minute of the motor, the car would be traveling 8.85 miles per hour on first speed; 14.65 miles per hour on second speed; 27.0 miles per hour on third speed and on reverse 6.86 miles per hour.

Rear Axle Gearbox Continued

As in the past, the Overland gearbox is mounted at the rear and bolts by means of a broad flange against the housing of the rear axle. The propeller shaft, which is of cold rolled steel, high forging stock, is 1.125 inches in diameter and is inclosed in a torque tube which is flanged at its rear end and is there connected to the gearbox, while at its forward end it terminates in a forked yoke which is connected flexibly to a cross member of the frame, thus permitting a rising and falling action of the rear axle. There is only one universal in the driving line and this is located at the front end of the driveshaft.

Three-Quarter Floating Rear Axle

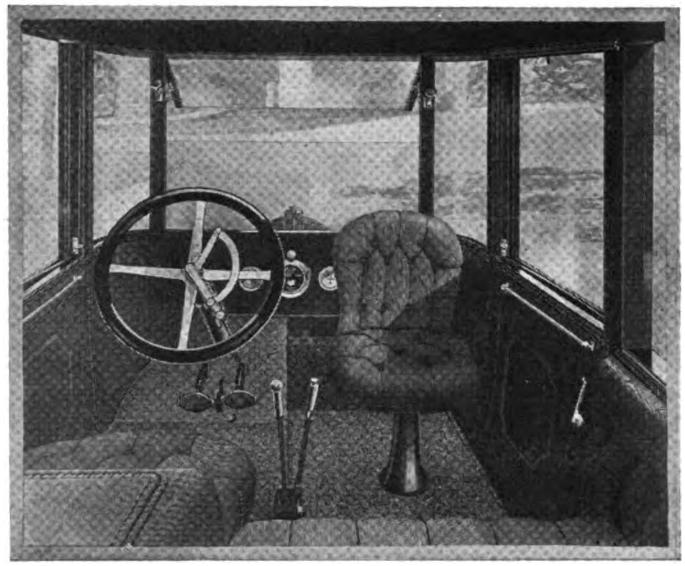
The floating rear axle is carried on Hyatt roller bearings. In this, the outer bearing is mounted on the outside of the axle housing. By this arrangement the shaft does not carry the weight of the car but merely transmits the driving stresses. There is a thrust bearing on the axle shaft at its inner end, which takes up any side thrust.

Longer Springs Are Used

Longer springs are now used to accommodate the larger body. The brakes are the same as on the Model 79, having a drum diameter of 13 inches inside. The front axle is new. It is a drop forged I-beam. The steering knuckle spindle is equipped with Timken taper roller bearings. While the steering gear has been moved over to the left side, it has not been changed in any other particular. It is an adjustable worm and full gear type with the housing bolted to the side frame. The steering wheel diameter is 18 inches and on this the spark and throttle levers are mounted as usual.

Touring, Roadster and Coupé Bodies

In body work the Overland car for 1915 provides either a five-passenger touring body or a two-passenger roadster. There is also the four-passenger coupé. The body is a streamline design and the frame, running-board brackets and battery box are concealed by mud shields, which add materially to the appearance of the car by giving it a long, low appearance. The swivel seat used in the coupé may be faced either forward or backward.



Interior view of Overland coupé. The entire interior is finished in Bedford cloth. Levers operate the windows, foot pedals are adjustable and all passengers face forward. This car sells for $1,600

Tires are carried at the rear on all models.

All cars come fully equipped with starting and lighting systems and carry side lamps, being one of the few 1915 designs which provide lamps in this position. The fenders are crowned and the latest ideas in top and upholstery work have been incorporated.

Chile Has Active Automobile Clubs

SANTIAGO DE CHILE, July 1—The Automobile Club of Chile has been organized with a membership of more than 135. The objects of the club are to establish clubhouses with all facilities for the members of the club, to report highway conditions and to study the possibilities of obtaining lower prices for imported fuel, tires and other necessities.

Another active Chilean Automobile Club is that of Valparaiso which is composed of some thirty members, all interested in the increase of the automobile industry.

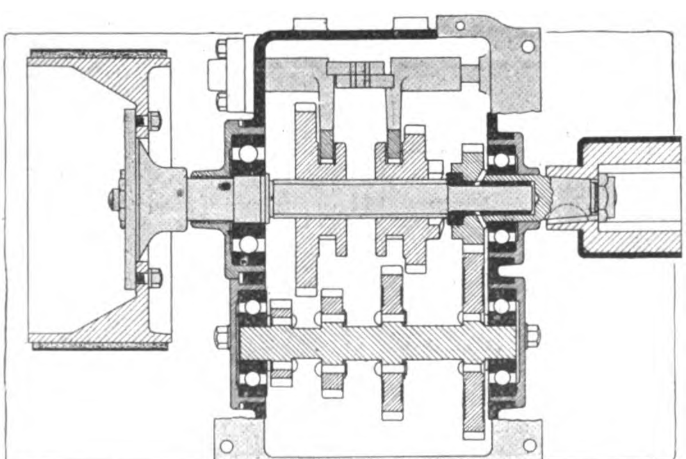
Franklin Uses Skew Bevel Drive

Many Detailed Body Refinements and Better Equipment—Prices $150 Lower on Series Six

IN bringing out the Series Six car which followed the Series Five without a break in production, the most important change that the Franklin company has made has been the reduction of $150 on the price of the touring cars and roadsters, while on the closed cars a still greater reduction has been made. The reason assigned for the reduction is that the factory has been able to reduce its costs by the concentration on one model, an occurrence of a year ago. By this concentration the use of special machinery and improved factory methods has practically doubled the factory output without increasing the building area.

The body lines of the Franklin are now more graceful than previous models. The body is larger, the seat sides higher and the upholstery finished off more luxuriously than ever before. The sloping hood has been continued, but has been given a more gradual slope, and this in connection with the use of a shutter effect on the front of the hood instead of the old-type grill has given a more sturdy and powerful appearance.



Sectional view of the gearbox showing shifter mechanism and bearing

In the motor only one slight change will be found and that is the fitting of the oil adjustment on the cowl board. The starter is lighter and more accessible than before, and, while it is still the Dyneto system, it has been improved so that it is now 40 pounds lighter than the model used last year. Both the commutator and brushes have been improved.

The only other change of importance on the chassis itself is in the rear axle. Now skew bevel gears are used, whereas previously the straight bevel type was employed. These gears are made by the Brown & Sharpe Mfg. Co., and had been adopted with a view to obtaining silent action. A number of little detail points such as the wing pivot bolts, front springs, magneto attachment, etc , have been improved. For instance, the magneto is now attached by means of two dowel pins and a divided metal strap over the top in place of the bolted-on brackets used last year. In the front springs the deflection was 1 inch to 180 pounds. It is now 1 inch to 200 pounds. No change whatever has been made in the rear springs. In the spring pivot bolts a new bushing has been employed which incorporates a felt washer intended to keep the dirt out and the oil in.

Cord Tires Standard Equipment

Better equipment will be found throughout the car. Most noticeable is the employment of either the Goodrich Silvertown cord or the Goodyear Power Saver tires as regular equipment. This is in line with the move made by makers of the highest priced cars for this season. Another provision this year which is an innovation for the Franklin company is the fitting of a power tire pump. This is a Hartford single-cylinder design and the pump itself, together with the bracket supporting it and the clutch for engaging it to the motor drive, only weighs 6.5 pounds. By the use of this power pump the Franklin company claims to have removed the only excuse for the heavier demountable rim in place of the Q.D. type which they employ. This light rim equipment is in line with the work throughout the car where everything has been done to make it as low in weight as possible. On the series six the Golde one-man top with curtains that can be operated from the inside will be found. On this top the side curtains fasten to the windshield, making a weather-tight joint. In adopting this top a new style of windshield had to be fitted and this is now the double-glass, rain vision, either half of which can be adjusted in any position.

Improvements in the Body Work

In the body work the front doors have been made wider and set back a little, permitting of easier passage in and out of the car. The mudguards are also wider to better protect the sides of the body from mud and water. They are made after the same pattern as the former mudguards, but the rivets are now invisible. The side lights have been eliminated and the headlights have been equipped with two bulbs. These are 12-volt types and are connected in parallel. The electric terminal connection has been moved under the cowl board and a trouble lamp with 12-foot cord is now supplied. The upper hinges of the door are concealed and the door handles are now on the inside. The battery location has been changed and while it was formerly invisible it is now both invisible and accessible, having been shifted from the chassis frame to a weather-tight box between the sill and the running board. The fuses are also located at this point so that it is easy to reach them for replacement.

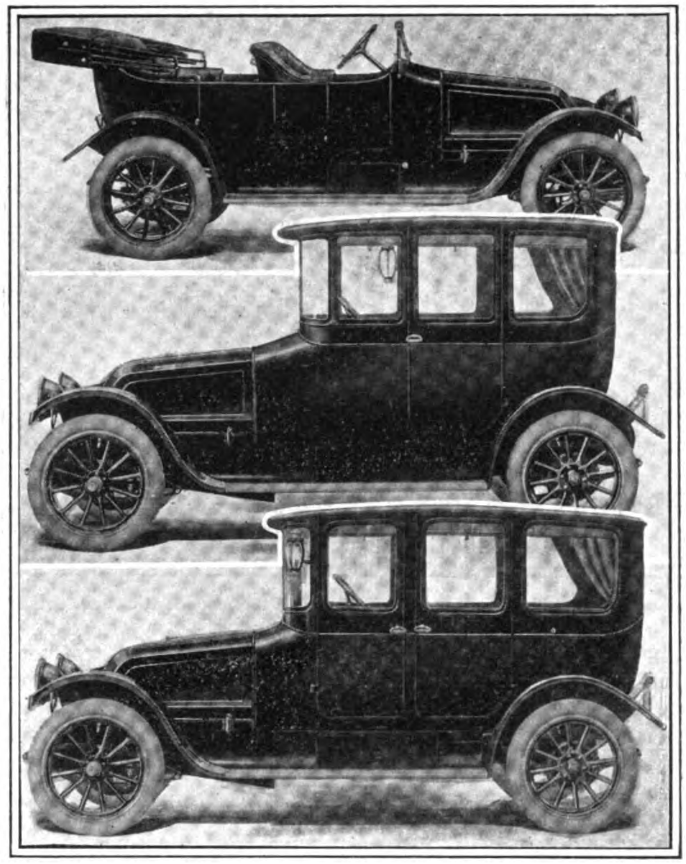
Luggage Carrier Regular Equipment

Franklin is one of the few cars which fit a luggage carrier as regular equipment. The design of this, however, has been improved still further, and now folds up closer to the body. Extra tire carriers are also provided on the rear of the car. The instruments for the control of the car are now mounted on a cowl control board directly below the windshield. This board carries a speedometer, horn button, hand-pressure pump, hot and cold air control, carbureter adjustment, oil control, starting and lighting switches. This gives a neater and more compact bank of switches than the previous design. The speedometer is also better, being a 60-mile Warner with a more accessible and more readily disconnected drive.

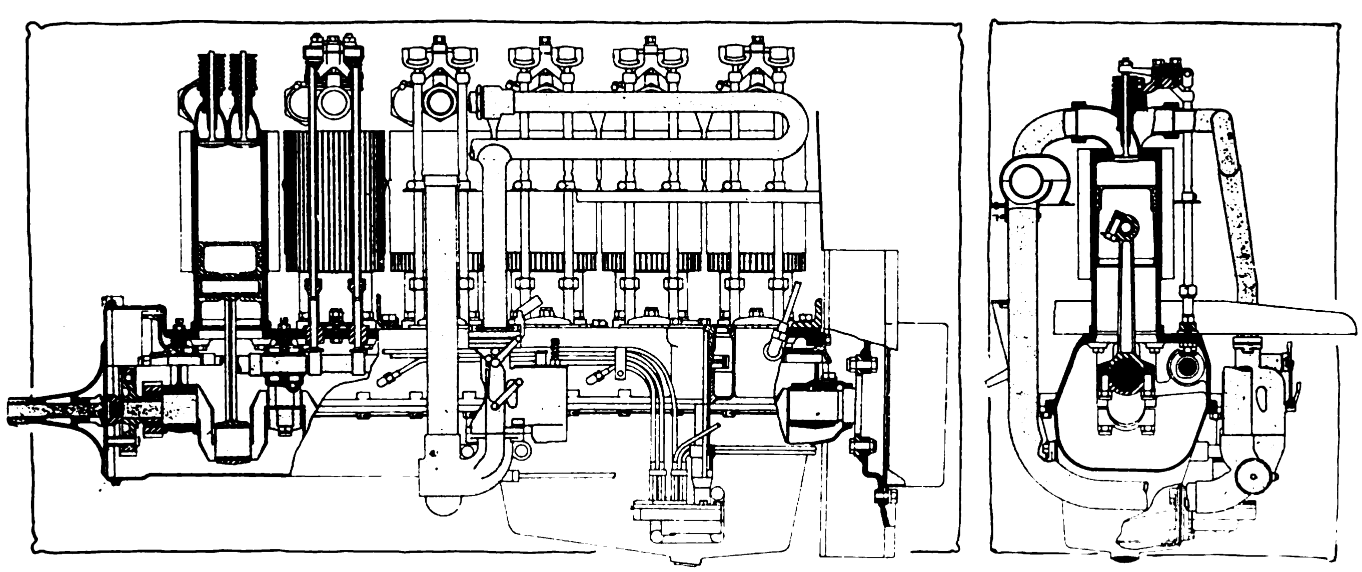
Air Cooling Is Continued

The air-cooling features of the Franklin car have not been changed. In fact, none of the typical features of Franklin design, such as the wood sills, elliptic springs and light-weight methods throughout the car are altered in any way. The six cylinders are cast independently and have a bore of 3.625 inches and a stroke of 4 inches. The valves are located in the head of the motor and their method of operation is shown in a longitudinal section of the motor given herewith. Each cylinder has an independent valve mechanism operated by an overhead rocker arm and each valve can be removed and reassembled without interfering with any other mechanism. The vertical air flanges surrounded by metal jackets are the main source of heat radiation in the direct cooling scheme used on the Franklin cars. The fan is a product of the Franklin company, having a series of blades which resemble the blades of a turbine.

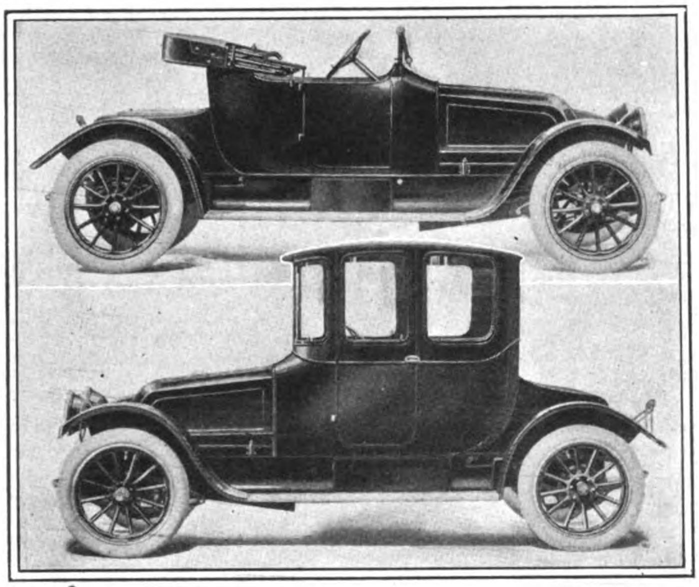
Seven main bearings of plain type are used to carry the



Three types of bodies which are standard on the Franklin chassis



Side view of motor showing a section through one of the cylinders and an end section taken transversely



Franklin roadster and coupé bodies. Note the gentle hood slope

crankshaft. These bearings are babbitt lined and are hand scraped. The bearing supports are bridges in the upper part of the crankcase which is cut through in the horizontal plane of the crankshaft axis. These bearings are lubricated directly by a circulating four-speed system. The oil is taken from the reservoir in the lower part of the crankcase, and forced by means of a gear pump driven off the camshaft through a series of individual leads, one of which passes to each main bearing. The oil sight feed on the dash is in the direct circulation line, and by its use the operator can at all times note the amount of oil passing through the system.

Dyneto Starting and Lighting System

For lighting and starting the 12-volt Dyneto outfit has been fitted. In mounting this electric system the primary object has been to make the motor generator as accessible as possible and at the same time to place it in such a position that it would be most apt to remain clean. The system consists of a motor generator connected to the crankshaft by a silent-chain drive. A storage battery floats on the line. The winding of the motor generator is such that it acts as a generator at speeds of above 12 miles per hour and at this time begins to charge the storage battery. At speeds below 12 miles per hour the motor generator acts as a starting motor and is drawing current from the battery which is utilized in cranking the engine. When the car is stopped there is a reverse current cutout which prevents the battery from discharging itself through the motor generator. For ignition an Eisemann magneto is used. This is mounted on the left and driven off the camshaft gear.

The Franklin company makes its own carbureter, and this season this will be found to be the same as in the previous model, except for the dash adjustment of the gasoline supply, which is a new feature. A rod operating on the needle valve and terminating on a ball-ended handle which is in easy reach of the driver secures immediate and perfect adjustment.

Emergency Fuel Arrangements

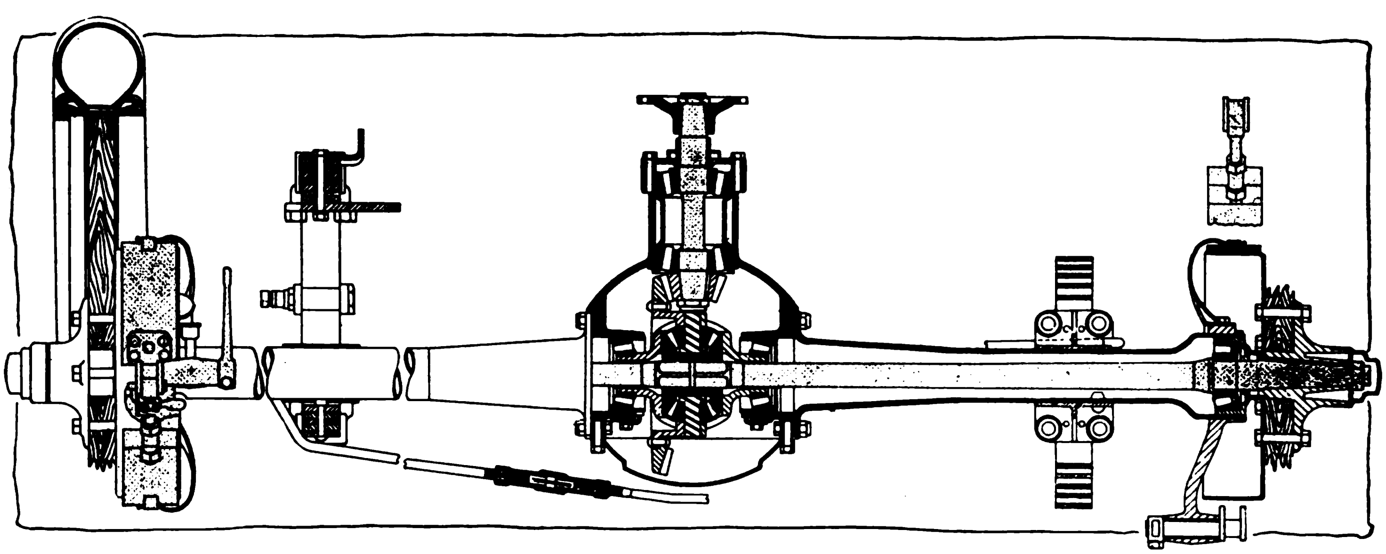
Gasoline is fed to the carbureter by gravity. The tank is located under the front seat and has a capacity of 14.5 gallons. There is a reserve tank of 2.5 gallons. There is a gasoline valve and separator in one fitting on the bottom of the gasoline tank and the handle for operating it is on the top of the tank, under the driver's cushion. The valve provides a main reserve and closed position and in this way the driver is always certain of sufficient fuel to reach the next supply station, should he be caught unaware.

No change will be found in the clutch. It is a multiple disk running in oil and is housed within the flywheel of the motor. A feature which is continued is the lubrication with graphite grease of the clutch trunnion by means of a cup carried on the sill of the car with a handle on the outside of the frame.

The amidship gearbox remains the same as in previous Franklin models. Three speeds are furnished and the gear-shifting mechanism is mounted in the center as before. On direct drive the reduction of the Franklin cars is 3.71 to 1. The rear axle is a semi-floating design which remains the same as in the series five except as the skew bevels replace the straight bevel. The differential and pinion shafts are carried on roller bearings. Taper roller bearings are used throughout the axle as will be noted in a reference to the sectional view of the axle given herewith. Aluminum is used throughout the car wherever possible, an example of this is the rear-axle gearcase which is a model of lightness.

Five Types of Bodies Fitted

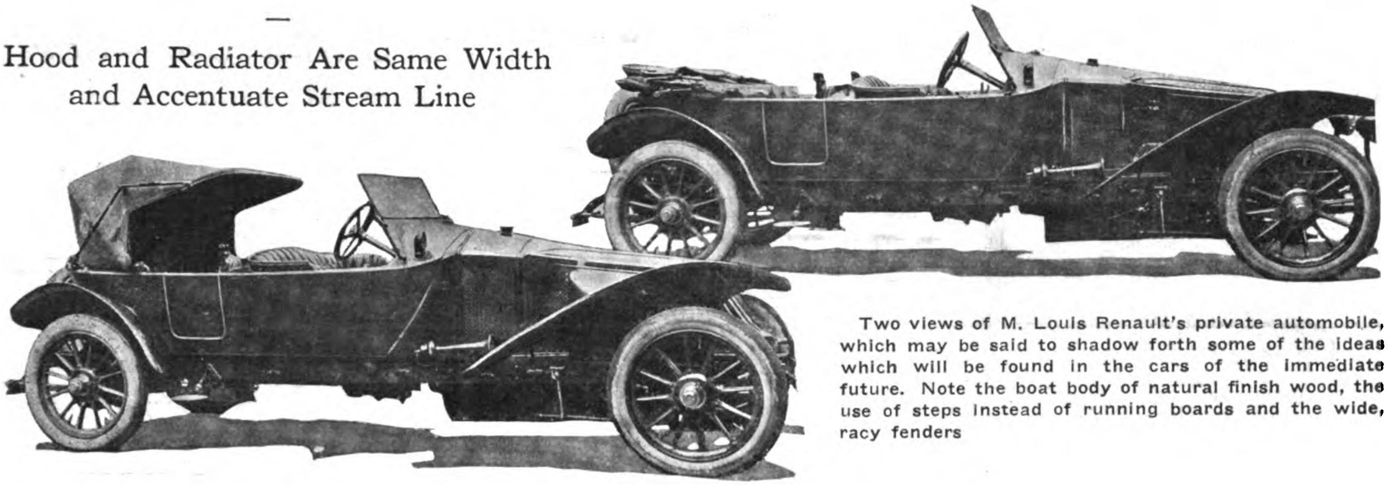
Five types of bodies are fitted to the one Franklin chassis. They are the touring car, roadster, coupé, sedan and berlin. The weights of these cars are respectively 2,750, 2,630, 2,788, 2,924 and 3,121 pounds, fully equipped. The standard color for all types is Brewster green with black trimmings. All the bodies are aluminum over a wood frame. The chassis frame is second-growth ash made in laminations. Full equipment is included in the selling price of the car.



Sectional view through the rear axle, which has not been changed except for the adoption of the skew bevel gear

Renault Has New Radiator Design

Hood and Radiator Are Same Width and Accentuate Stream Line



Two views of M. Louis Renault's private automobile, which may be said to shadow forth some of the ideas which will be found in the cars of the immediate future. Note the boat body of natural finish wood, the use of steps instead of running boards and the wide, racy fenders

PARIS, July 29—Interest attaches to Louis Renault's private automobile by reason of the fact that it is the forerunner of the cars which will be offered to the public for the 1915 season. No technical details regarding the car are available, but there are a number of features which can be observed by an external examination.

The most important of these is the new shape of radiator and hood. Instead of the radiator standing out wider than the hood, leaving a number of tubes exposed on each side of it, the rear of the hood is now the same width as the radiator and forms an unbroken line with it.

Radiator Is Lower

The radiator is also made considerably lower, so that the top of the hood, the top of the radiator and the scuttle dash form an unbroken line. In order to get the same cooling efficiency as when the tubes were directly exposed to the draft, the radiator is made considerably deeper than formerly and the rear portion of the hood is cut away and a metallic trellis fitted in each side. By this arrangement Renault maintains his sloping hood and yet secures the unbroken line which up to the present has only been attainable with the radiator in front design.

Boat Body of Wood

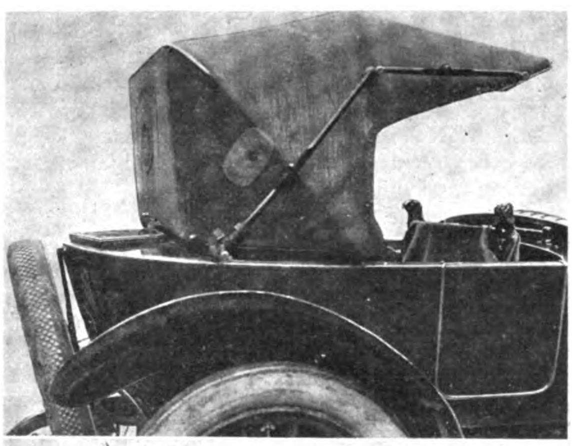
This chassis carries a special sporting type boat-built body polished in the natural wood. It is joined up to the radiator without any break in the continuity of the lines, and has a wind screen with the lower portion permanently tilted rearwards.

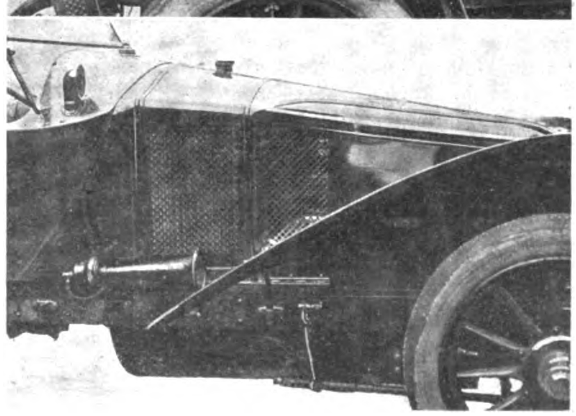
Steamship ventilator cowls are carried on the top of the scuttle dash in order to supply air to the fore compartment. Electric lighting is now a standard equipment, the generating motor being at the fore end of the motor under the hood. Batteries are carried within the frame member, alongside the driveshaft.

Detachable Wood Wheels

This car is equipped with Renault detachable wood wheels, which now form a part of the standard equipment.

The boat-built body has no running boards, but merely a step for each door. The top is of the Victoria type covering the rear seats only. Right in the stern of the boat body is a tool locker, with admission to it through a hinged locker in the boat deck. Rear suspension remains unchanged, being provided by long semi-elliptical underslung springs.





Above—Victoria type top and provision for carrying spare wood demountable wheel at rear. Note rear deck of boat body

Lower—How the radiator slopes into the hood on Renault car. Note steamship type ventilator in cowl

Smooth Body Lines

An inspection of the accompanying illustrations will give the reader an idea of the attractive qualities of the design, the smooth sweep of the body lines and the harmonious blending of the radiator and bonnet.

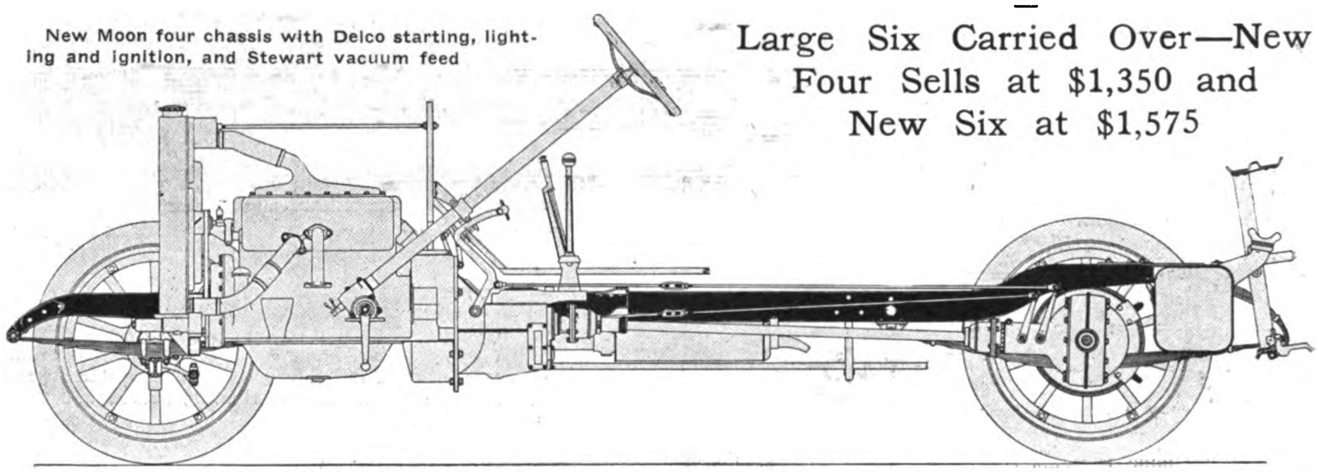
One somewhat discordant note is the mounting of the electric horn on the outside at the right of the radiator. This, however, could easily have been avoided. The sweeping lines of the fenders give the car a racy appearance, which is heightened by the absence of running boards.

In the illustrations at the left some of the detail features of this new car may be seen somewhat more clearly than in the illustrations of the entire car at the top of the page. For instance, the method of carrying the spare demountable wood wheel at the end of the rear deck may be seen in the upper illustration which also shows the tool compartment in the rear deck, the robe rail at the back of the front seat and the Victoria top.

Moon Has New Four and Small Six

Large Six Carried Over—New Four Sells at $1,350 and New Six at $1,575

New Moon four chassis with Delco starting, lighting and ignition, and Stewart vacuum feed



THE 1915 season of the Moon Motor Car Co. is being confined to three models, two sixes and a four, of which only one, which is known as the large six, being a carried-over model. The two models are a four and a six, the four selling at $1,350 and the six at $1,575.

All three models use Continental motors, 1915 marking the close of the Moon-made motor in any models. These motors all lean to the long-stroke classification. The small four has cylinders 3.75 by 5. In the small six the sizes are 3.5 by 5 and in the larger six the cylinders measure 3.75 by 5.25. The four and small six use L-head block types and the larger six has the cylinders in blocks of three.

Other features of the line are Delco starting, lighting and ignition; Stewart vacuum gasoline feed; Hotchkiss drive from the rear axle to the frame in which the torque rod is eliminated, and improved streamline bodies.

Although all three models give evidence of Moon practice of 1914, there have been a number of mechanical changes with a view to decreasing weight, improving the riding qualities and giving better service. The new four and new six are equipped with roadster and five-passenger touring bodies only, at the price mentioned, while the larger six comes through with roadster, four-, six- and seven-passenger bodies. It lists at $2,250.

The 4-38, the four-cylinder model, and the 6-40, the small six, entirely new cars for this season, are somewhat similar in construction and in the general outside appearance. The four has shown 21 miles to the gallon of gasoline according to the Moon company.

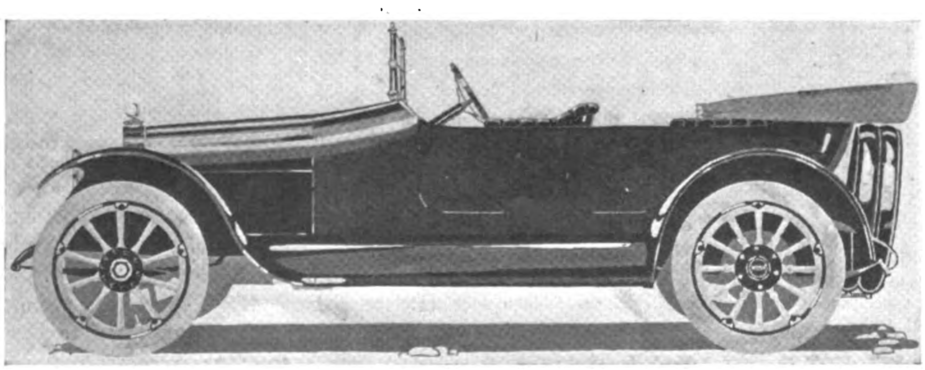
It is stated that this engine shows 44 horsepower at 2,200 revolutions per minute. An improved one-wire Delco starting, lighting and ignition system is used and an added feature this year is the Stewart-Warner vacuum feed by which the carbureter is fed by gravity even though the fuel tank is located in the rear of the chassis. The engine drive is taken by a dry disk clutch and then by a three-speed selective gearset, both of these members, with the motor, forming a unit power plant. Both clutch and gearset are products of the Warner Gear Co., Muncie, Ind.

The propulsion of this car as well as the new six is by the Hotchkiss drive which eliminates the torque rod, simplifies the chassis and makes the springs take the driving strains. A new type of braking system is used in all the 1915 cars, designed by engineer H. L. Goodspeed who has reduced the number of system parts from fifty to twenty-two. In the 1914 cars an equalizer system was in use which required a long equalizing beam at about the center of the chassis. In the new system a more direct action from pedal to brake bands is obtained with the equalizing beam in the rear almost above the rear axle housing. Brake adjustment is easier and danger of binding from lack of lubrication is eliminated.

Underslung Springs on Four

The 4-38 has a wheelbase of 120 inches and has underslung rear springs which so lower the body as to give it a decidedly smart appearance. This body, as well as those of the other Moon cars, is of the true streamline type with a graceful curve from the windshield base to the radiator. The latter is a new one with a slightly rounded front. The driver's compartment has 44 inches of leg room and the tonneau is also comparatively roomy. Concealed hinges and locks, clean running boards, crowned fenders and other features in demand are to be seen. Drive is on the left with control levers in the center with the instruments well grouped on the cowl board. The headlights have dimmer control.

The new six possesses many of the features of the new four but with its longer wheelbase, greater power and light weight, supplies the demand for a car midway between a four and a heavier six. The Continental motor is of L-head construction, with cylinders cast in block. All Continental features such as helical timing gears, splash-pressure oil-feed, large bearings, etc., are to be seen.

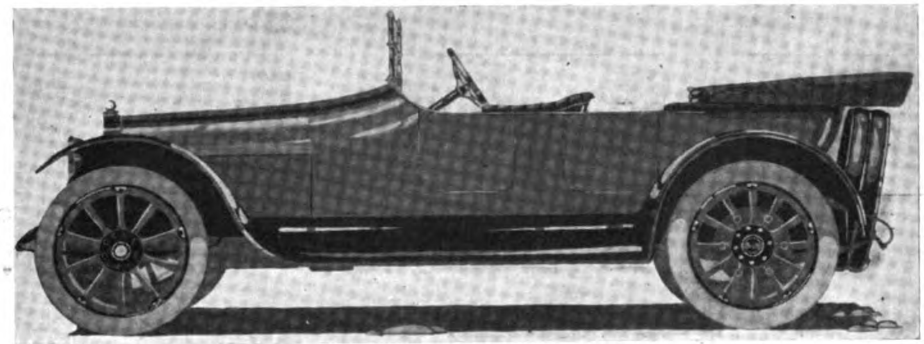


New Moon four-cylinder listing at $1,350

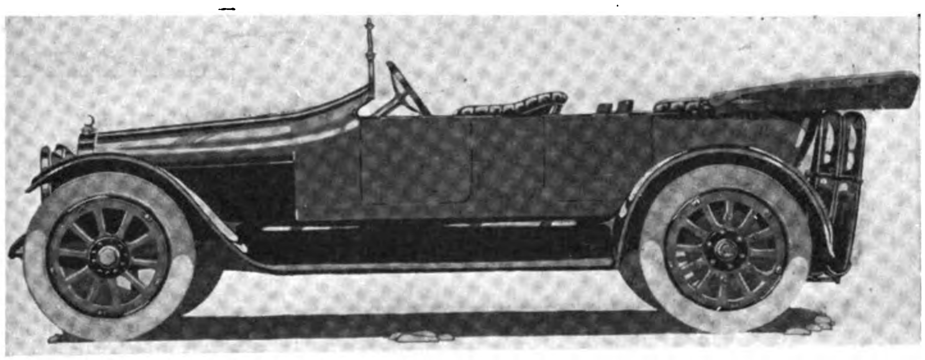
Clutch and Gearset in Unit

The clutch and gearset, in unit with the motor, are of similar general design as those used in the four, but the parts are slightly heavier to care for the greater strains. The drive from the three-speed gearset to the floating rear axle is by shaft and bevel gearing. The new brake equalizing system described in a previous paragraph is a feature of this car also. The springs are underslung and the drive is taken through them as in the four, eliminating all the usual driving members. In order to obtain a short turning radius the frame has been narrowed in front.

The streamline body is somewhat on the same order as that used on the four. Drive is left with control in the center and the cowl arrangement, carrying of the extra tires in the the rear and the general interior body arrangement is the same as in the four. The wheelbase is 120 inches and the tires 34 by 4 inches.



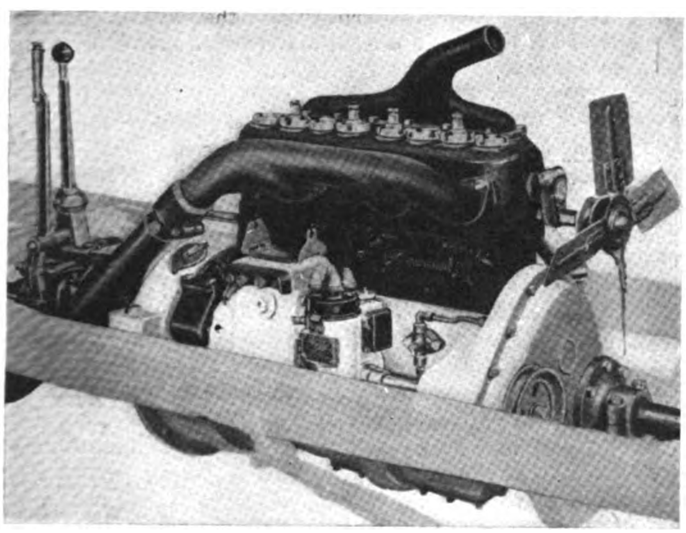
New Moon light six selling for $1,575. It has a block motor. The drive is taken through the underslung springs, as in the four-cylinder car



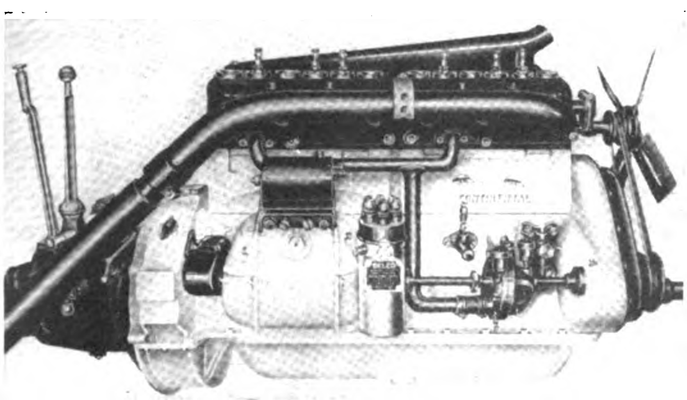
Moon large six with L-head motor 3.75 by 5.25 inches

Large Six Wheelbase Increased

The changes in the 6-50 or large six are important ones. The wheelbase has been increased from 129 to 130 inches, the doors widened from 21 to 22 inches, the rear seat upholstery has been made deeper, more leg room has been provided for the driver and the tonneau extra seats are improved. The disk clutch has been reconstructed and the method of holding the plates changed so that wear is reduced. It is stated by the company that 150 pounds has been cut from the rear axle, due principally to the adoption of a crucible steel housing instead of the malleable iron one used in 1914. The brake drums have been increased from 14 to 16 inches in diameter, the silent chain drive of the Delco distributor adopted and a new braking system installed.



Exhaust side of Moon 4-38 motor for 1915



Exhaust side of Moon 6-40 motor used in light six. Note mounting of Delco electrical system

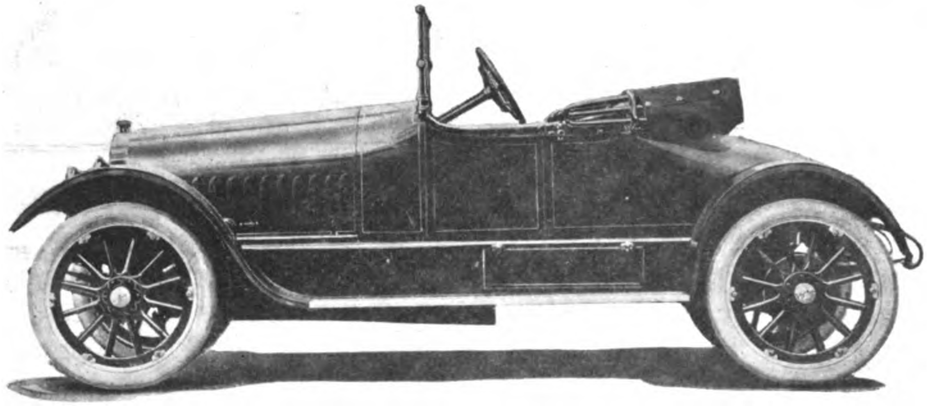
The body has very pleasing lines and the tonneau and driver's compartments are roomier. The tires used are 35 by 4 1-2 inches and the equipment includes Stewart-Warner vacuum fuel feed, headlight dimmers, top with boot which also covers the top bows, Delco system, clock speedometer and other instruments set flush in the cowl board and Collins curtains, as well as a Klaxon horn.

The carried over model, the 6-50, has the same engine as used in the 1914 model with improvements in detail and the equipment necessary to bring it up to date. The cylinders have a bore and stroke of 3 3-4 by 5 1-4 inches, and are cast in blocks of three. The Delco system of improved design has been installed and the circuit breaker feature of last year retained. With this breaker it is possible to tell whether there is an open or short circuit in the system. The battery for this system is an Exide and is placed behind the apron near the front right fender. Circulating splash oiling is used and cooling is by centrifugal pump driven by shaft from the timing gears.

The new type of disk clutch has been placed in this chassis but the gearset of last year, a four-speed affair, has been retained without changes. The floating rear axle and Moon one-piece axle housing are as before, with the exception that a reduction in weight has been made. The springs of this car are overhung and the drive is by torque members as in the 1914 model. The new type of brake equalizing system is used on this model. A rear axle feature is the centrifugal oil-draining device inside the hubs. This device gathers oil likely to make its way from the differential housing to the brake drums.

Unbroken Lines on 1915 Herff-Brooks

Price Unchanged on Four and Six —Steering Wheel Hinged—Extra Seat in Four



Smooth lines of 1915 Herff-Brooks six-cylinder roadster

TWO cars, a four and a six, are announced as the 1915 line of the Herff-Brooks Corp., Indianapolis, Ind., with unchanged prices at $1,100 and $1,375 respectively, but with a great number of mechanical and body changes which mark them as distinctive types of the coming season. A complete transformation has been effected by entirely new body lines, which give the cars a foreign look. The hood has no break, making a long sweep from the cowl to the newly shaped radiator, with generous curves from the cowl to the rear. But the fight for improvement has not stopped with the new bodies, for there are two other attractive features which stand out above the rest. The steering wheel of the 1915 Herff-Brooks four and six is of the folding down type. This wheel is hinged to the post on one side and when desired it may be folded back so that entrance and exit from either side of the car is easy. The five-passenger touring cars now contain an extra seat for a sixth passenger, this auxiliary chair folding into a tool box under the front seat. Right drive and center control have been abandoned on all models and left drive with center control adopted.

Wheelbase of Four Longer

Aside from the feature changes mentioned a number of mechanical improvements have been made in both four and six. The wheelbase of the four has been lengthened 2 inches, from 116 to 118 inches, and the bore increased from 4 1-8 to 4 1-2 inches. Bosch ignition supplants the magneto and dry cells of the 1914 four and six and a Stromberg carbureter is used instead of the one supplied previously. The old-style top gives way to an improved one-man top.

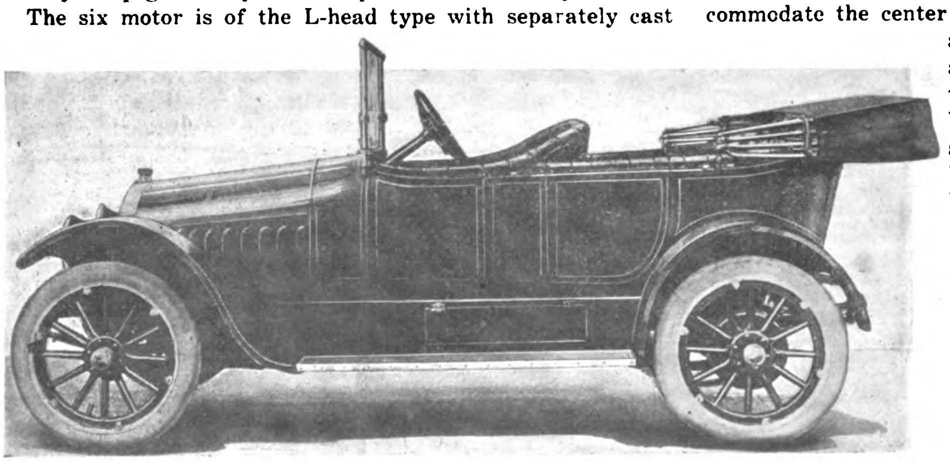
The six motor is of the L-head type with separately cast cylinders with individual valve inclosures to exclude dirt and house noise. The bore and stroke of this motor is 4 by 4 1-2 inches, the same dimensions having been used in 1914. Cooling is by pump circulation with the pump in front of the timing gear case, a rather unusual position for this member. Behind the pump is the new Bosch magneto and on the same side is the newly-adopted Stromberg carbureter. The right side of the engine is clean except for the crankcase breather and the water pipe. Lubrication is by splash-pressure in which oil is carried by a gear pump from a crankcase sump, sent through a strainer and then to a sight feed on the dash from which it makes its way to individual troughs under the connecting-rods.

Six Motor Has Seven Bearings

The motor having separately cast cylinders, calls for a crankshaft with more than the usual number of supports. Seven are used in this engine each 1 3-4 inches in diameter. The camshaft requires but three supports and this shaft operates push rods moving in square guides instead of round ones which are usually seen. The valves are 1 7-8 inches diameter and have a 5-16 inch lift. The timing gears are helically cut. A semi-steel mixture is used for crankcase metal and the case is supported by four arms cast with the crankcase. Every casting in this, as well as the four motor, comes from the Herff-Brooks foundry.

Clutch design has not been altered appreciably. The clutch is of the inverted cone type with spring inserts and incorporated with this clutch is a brake which prevents spinning when making gear changes. The gearset which is of the three-speed selective type has been redesigned to accommodate the center control feature, but the gears, shafts and general arrangement is the same as that used on the 1914 six. From the gearset to the rear axle no changes have been made. The inclosed drive shaft is equipped with one universal of large size and within this joint is a hollow brass compartment which holds sufficient grease to lubricate it for 5,000 miles. This is but one instance of removing the periodic greasing tour from the owner and in many instances oiling is taken care of automatically. The rear axle is of the semi-floating type and operates on ball bearings.

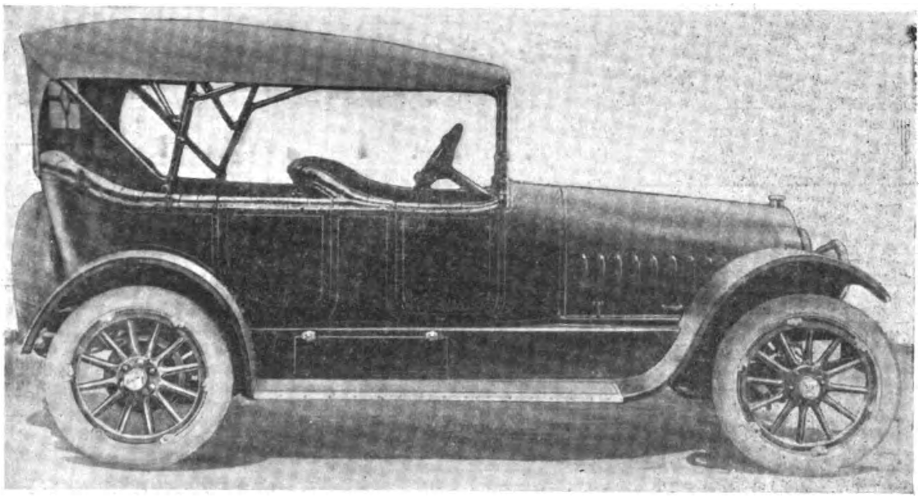
The new Aplco starting and lighting system is of the single-unit type, the motor-generator being driven by silent



Herff-Brooks four-cylinder car with extra seat for sixth passenger chain from the shaft extending from motor to gearset. The battery for this system is supported by steel hangers under the tonneau floorboards where it is accessible.

The new six body is much larger than the 1914 body and is an entirely new job throughout, as mentioned previously. All the instruments are finished in black and nickel and are mounted on a board where they can be reached easily by the driver.

The 1915 Herff-Brooks four has a larger motor, the new dimensions being 4 1-2 by 5 inches against 4 1-8 by 5 inches used in 1914. This engine is of the L-head type and has its cylinders cast in block. The oiling, cooling, carburetion, ignition, starting and lighting units are the same on the four as on the six and it differs only in general design. The crankshaft is supported by five bearings, the push rod guides are held in place by clamps, which practice is not used on the six. From the motor to the rear axle the four and six are similar in design, but the latter is smaller in proportion. All chassis receive a thorough test and are rigidly inspected before leaving the factory.



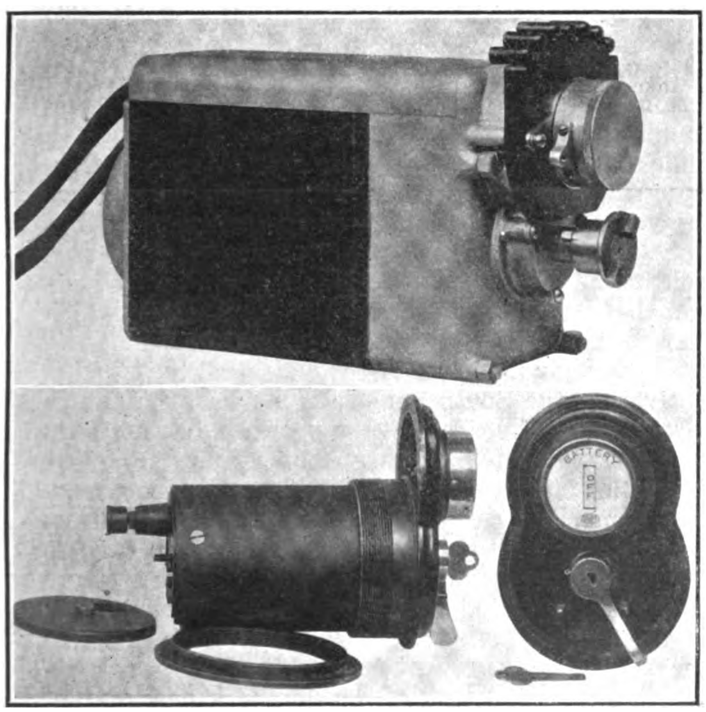
Herff-Brooks six-cylinder with one-man top, smooth lines and clean running boards

Samson Engineering Co. Brings Out Starter

THE Samson Engineering Co., recently incorporated under the laws of Kentucky, with a capitalization of $350,000, and with headquarters in Louisville, Ky., will shortly have on the market a starting, lighting and ignition system.

One unit performs all these functions, and it is arranged to be driven at crankshaft speed. All reducing gears are integral with the machine. The wiring is extremely simple, using a grounded return. No cutout or regulator is used in this system, as the ignition switch connects the armature to the battery, and provision is made for automatically tripping this switch if it is left on by oversight.

The same voltage is used for the lamps as for the starting; this can be either 6 or 12 volts, as specified.



Samson unit starting, lighting and ignition system. Upper view shows complete unit and, lower, the dash coil and switch

The motor-generator armature is arranged in four multiple circuits, which by means of the brush arrangement allows the starting current to produce maximum torque and the generating current is produced by connecting the multiple circuits in series to produce low-speed generating values.

The starting switch is built into the generator and connects directly to a push-rod or pedal, there being no gears to mesh. The gear reduction is of such construction that the engine is free at all times. Arrangement is provided that a back fire from pre-ignition will allow the engine to reverse its motion without exerting a strain upon the starter.

The voltage regulation is taken care of by having the shunt field connected across one multiple circuit so that its current is tapered off in proportion to the voltage drop, due to the current increase in the armature turns.

The current delivered by the armature curve obtains its maximum at 400 revolutions per minute, and has a tapering characteristic from this point, diminishing approximately 50 per cent. at 1,500 revolutions per minute.

The transformer and breaker design is such that the current through the primary circuit is of equal value at high and low engine speeds, it being impossible by this method to get full efficiency from the engine at extreme high speeds without consuming too much current for the ignition at low speed. The ignition current being of such low value does not disintegrate the breaker points.

The ignition is automatically advanced and arranged for hand-control if desired.

The dash coil carries upon its face an indicator showing the charging, provision also being made for emergency dry-cell ignition. A removable key is provided to lock the ignition lever.

The starter is designed so that it is easy to get to all points for cleaning and inspection. It is also dust and waterproof.

Two types of these starters will be put upon the market:

Type A, which is designed for the largest cars and weighs approximately 60 pounds complete. Type B, which is designed to crank a 3 1-2 by 5, six-cylinder motor, and weighs approximately 40 pounds.

The cranking speed on both these models is over 100 revolutions per minute, the current consumption being well within the range of a medium-sized battery.

Two Tire Blades

THE effects of the European war have been brought closer to the American automobile owner by the increase in tire prices than was deemed possible a month ago. In a week the price of crude rubber has jumped from 55 cents per pound to $1.10. Where the price limit is no one knows. The British ships, which bring the crude to our shores, are largely tied up by the war hostilities, and should a war of many months continue we would be confronted with a serious tire crisis by next spring.

"Making two blades of grass grow where one formerly grew" can perhaps to-day be applied in the tire field. If we can add 1000 miles to the life of a tire it should be done. Tire makers, in addition to boosting prices should start a country-wide campaign of education on greater tire care. Attention can be drawn to more careful watchfulness of the inflation pressures, to the more accurate alignment of the vehicle wheels and to the repairing of tread cuts to prevent water entering and rotting the fabric. There is ample room for missionary work of this nature. There is a big field in which to cultivate the second blade. A campaign for slightly slower speeds, cutting 5 miles per hour off, will accomplish much.

"I'll Find a Way or Make It"

WITH overcast skies and the smoke of battle filling Europe from corner to corner; with commerce on the high seas at a standstill with many companies to which American automobiles have been exporting; with some gates of motor car supplies from Europe locked by the armed hostilities, and with every country in the civilized world more or less directly or indirectly affected by the turmoils of war precipitated a week ago, the American automobile maker must view the situation calmly. Instead of weeping over what has already been lost and mooding over the gloom that the future may unfold, it is the better part to pin on the old Roman badge, "I'll find a way or make it."

But a short fortnight ago America was on the crest of its European export boom. Business was coming our way. The powerful cumulative force of years spent in developing export business seemed to be lending its impetus to increase future business. But just when the sun shone with brightest splendor the sullen boom of the distant guns was heard, and to-day the work of years seems temporarily suspended, and for how long no one but the gods can answer.

Already the dire results of the war are being experienced in America in spite of her neutrality. Sales of cars in those countries directly engaged in the war have practically ceased. Buyers are refusing to take deliveries in France, and the situation is still more acute in Germany. Before war was declared French factories had suspended all buying, some of them had partially closed down, and with the declaration of war it was expected that every factory would close its doors. For the time production in Europe has practically ceased, but still supply is not dropping behind demand because demand ceased at the same instant.

Our makers will have to turn to other fields. To our south lies another continent, South America, settled largely by those of Latin origin, with Anglo-Saxons in some parts. At present Europe commands the big business in Brazil, in Argentina, in Chile and the other countries in South America. Germany has had large trade with them; France has enjoyed a large percentage of the business, as has Italy. These countries of South America must now look to the United States for many of the products that they have been purchasing in Europe, but which they cannot obtain at present. Here lies the opportunity for our makers. Already several have begun cultivating the South American market, the efforts covering 6 or 7 years, but the progress has not been up to par. To-day offers an opportunity for more intensified cultivation of this field as an export market. American car builders who have received orders to cancel all shipments to Europe can turn to the South. Accessory makers, and there are many of them confronted with similar cancellations, will have to follow the same policy, and where 12 or 20 per cent. of their product reached the European market, it will be the task of developing a new market for this in South America.

Rubber Shipments Affected by War —Tire Prices Climb

Values of Crude Product of Plantation Quality Rise from 55 Cents a Pound on August 1 to $1.10—Eastern Sailings Cancelled—Brazil Season Off

NEW YORK CITY, Aug. 10—Crude rubber has reached the remarkable market price of $1.10 a pound for plantation quality and $1.12 for Para, climbing since August 1 from respective prices of 55 and 70 cents.

This doubling of values of the important commodity is due to the effect of the European war on shipments of rubber from the great plantations of Ceylon and the Malay states that produce two-thirds of the world's supply. All Far Eastern rubber cargoes are cleared out of Singapore for London, the primary rubber market. Sailings from both of these ports have been cancelled.

The establishment of an American merchant marine or a decisive battle at sea or peace are the only vistas of hope that importers hold up to the automobile industry.

Stores of free—non-contracted—crude rubber in New York City, it is said, do not exceed 500 tons. London has about 1,000 tons collected on shipping docks. Perhaps 1,000 tons are now en route for and about 1,000 tons actually being unloaded in this country.

Altogether the supply in sight appears slim when it is realized that the consumption in America is about 65,000 tons a year.

And there is no hope from Brazil or Mexico at this time, say the importers.

"A small stock probably has accumulated in Brazil and Para that wouldn't last one of our factories a few days," said Francis R. Henderson, of the rubber importing firm of Henderson and Korn today.

"This small stock will reach us easily as shipments from Brazil have not yet been affected—and they probably won't be. The Booth line, English, controls the Brazilian shipping, of course, but there is talk of turning over all of the business to the Lloyd Braziliero, the Brazilian line that sold out to Booth. Under the neutral Brazilian flag, cargoes will come safely and regularly.

"But this doesn't help the rubber situation a trifle. At this time of the year nearly all of the world's supply of rubber comes from Singapore. As a matter of fact, most of the world's supply of rubber at any time of the year clears out of Singapore, coming from Ceylon and the Malay states, largely the latter.

"The Brazilian crop moves from October 1 to April 30. Rubber is not gathered during other times of the year, as the country is flooded with torrential rains and the plantations have to be abandoned. During the harvest season there is a steady market, so that no stores are permitted to accumulate. Therefore, we can not depend on Brazil until after the first of October and then only for normal quantities.

"The normal Brazilian rubber crop is now about 40,000 tons. American industries consume between 65,000 and 70,000 tons a year.

"The great rubber fields of the Far East, however, produced 70,000 tons in the last year and that is why all eyes in the rubber world turn East. The crop is an all-year-'round one. Incidentally, the rubber harvest is now in Ceylon and Malay, the yield being very small until about 10 years ago when it suddenly began to pick up and outstripped all others.

"Mexico offers no hope. The little crop there of past years probably is zero this year because of the revolution. Mexico couldn't keep one factory busy a week.

"We have no idea what factory stocks may be. Factories buy from us.

"There is nothing that we can do to relieve the situation. It seems to be up to the United States just now. No banking relief is needed. What we need is ships, ships that won't be interfered with on the high seas, and plenty of ships."

Most Tire Companies Advance Prices 10 to 20 Per Cent.

NEW YORK CITY, Aug. 10—The price of tires has been raised by nearly all the larger tire companies from 10 to 20 per cent. The action is due to the effect of the European war upon the crude rubber situation, the price of the crude product having advanced 100 per cent. in the eight days ending last Friday, August 7.

Crude rubber is just as plentiful as ever, but the war has tied up the London rubber market, through which most of the rubber used in the United States is bought, and English ships, which carry most of the rubber from East India and Brazil, are wary about navigating when hostile battleships are likely to molest them.

After affairs adjust themselves it may be possible for neutral vessels to supply the demand by transporting Para rubber from South America; also the war may not last long, all of which may relieve the situation; but as it is the majority of American tire builders have no more than enough to last them from six weeks to three months.

The tire-buying season, however, is about over, July and August are the two big tire months of the year and in September the demand falls off as touring declines. For this reason tire manufacturers generally carry a low stock of crude rubber at this time of year and work the made-up stock down low in cleaning out for the following season.

Also since manufacturers with long-time contracts were badly "stung" a couple of years ago when the price dropped they have bought more or less from month to month ever since and none of them carry very heavy stocks. Whatever contracts exist are for a certain quantity to be delivered every month and at this time the rubber traders are unable to fulfill their contracts.

Price Movement in Principal Makes of Tires

34 x 4 Size

Make of Tire	Per cent of Increase	Plain		Non-skid		Tube		Date in Effect
		Was	Is	Was	Is	Was	Is	
Empire	12.5	$24.35	$27.40	$30.50	$33.85	$5.45	$6.25	Aug. 11
Federal	12.5							
Firestone	12.5-15	26.20	29.45	30.50	33.85	Gray 4.90 Red 5.45	5.65 6.25	Aug. 7
Fisk—Bolted-on	15	30.30	34.85	36.35	41.80	5.60	6.45	Aug. 8
All others	15	26.25	30.30	31.60	36.35	5.60	6.45	Aug. 8

Kelly-Springfield	None will be made.							
Lee	None as yet.							
McGraw	Probably will advance.							
Michelin	None expected to be made.							
Overman	None to be made for the present.							
Pennsylvania	12.5 Prices being adjusted.							
Racine	None as yet.							
Republic	About 12.5 to 15.							
Swinehart	No raise. 10 per cent cut from dealers' and consumers' discounts.							
United States	12.5	24.35	27.40	33.55	37.75	Red 5.42 Gray 4.90	6.15 5.50	Aug. 8

The price of tires, beginning nearly a year ago, dropped a total of 28 per cent. This was due to competition and a low price for crude rubber. The present increase has sent it about half-way back and whether other increases are contemplated would not be stated by the tire men.

Should the war end in a short time, one tire man stated, the price of crude rubber would probably go lower in this country than it had been. This, he said, would be caused by the inability of European factories to recover their normal condition and take the rubber offered by the world's markets, all of which rubber would be sent to this country and glut the market.

Present Advance Based on Apprehension

The tires which are being sold at the present time and on which the price has been raised are not being made from the crude stock on which the price jumped. The increase in tire prices is based more upon a feeling of apprehension as to future conditions and it will be several weeks in most cases before any of the high-priced crude is made into tires

Because of this some of the manufacturers have declined to raise until the cost of production increases. The Kelly-Springfield, Ajax-Grieb and Michelin companies are standing pat on their former prices, and the attitude of those who state that they will not raise is indicated in the statement of Van H. Cartmell, president of the Kelly-Springfield Tire Co.:

"We always base our selling price on our manufacturing cost," he stated, "and while we are able to manufacture at former and present prices we shall not raise the retail price of our tires. If the war should continue and it becomes necessary for us to make future purchases of crude rubber at advanced prices we would increase the selling price in proportion to the advance in the manufacturing cost."

Horace De Lisser, chairman of the Board of Directors of the Ajax-Grieb Rubber Co., expressed a like sentiment. Mr. De Lisser urged manufacturers to maintain an attitude of calm and said no increase would be made in Ajax tires until the cost of making them was increased by the necessity for purchasing crude rubber at advanced prices. This company is not heavily stocked with crude or tires, but is selling at former prices.

The increases made range from 10 to 20 per cent., the average being from 12.5 to 15 per cent. The highest increase was made by the Goodyear Tire & Rubber Co., Akron, O., which advanced 20 per cent. The Fisk Rubber Co., Chicopee Falls, Mass., was next in line with 15 per cent.

Goodrich and Diamond tires went up 12.5 per cent., as did Empire, Pennsylvania, Federal and United States. Republic's increase, like that of Firestone, ranges between 12.5 and 15 per cent.

Racine, Lee, McGraw and many others, many of them lesser manufacturers, have not made advances and state that they have not yet made decision. In many cases, however, the "little fellows" plan to imitate the big ones.

Instead Cuts Discounts

Swinehart did not raise its list price, but instead cut the discounts given to the dealer and the consumer. Where the dealer got, for instance, 10 and 10, he now gets 10 only, and where the consumer got 10 and 5 for cash, he now gets 5 for cash. The dealer is credited with having cut from the list under the previous arrangement, so that in order to make his former profit he will have to sell at list without a cut.

The dealers' discounts remain unaltered in other cases. They range from about 15 to 25 per cent. In some cases there will be a slight adjustment, but it will not be radical.

The movement in solid tires is erratic. United States boosted the price 15 per cent., while others state that they will not raise or have not made decision. It was stated by one tire man that the price of solids would not necessarily follow pneumatics inasmuch as solids may be built of less costly material and still be highly satisfactory. Para and a cheaper rubber—sometimes reclaimed—is used in solid tires. Firestone made a move in solids like that of Swinehart in pneumatics and cut the discount by 10 per cent. of the list.

Tire importers have supplies on hand for about six months and hope their European factories will be running again by the first of the year. In New York there are several imported tires; Prowodnik, made in Riga, Russia; Englebert, made in Liege, Belgium; Gaulois, made in Clermont-Ferrand, France.

The Gaulois Tire Corp. luckily got in three separate cargoes early this week and is well fixed. The Columb Tyres Import Co. has a good stock of Prowodniks. The Englebert Tyre Co. received cable advices that the factory, which is on the battle line of the Belgian and German armies, is at present practically at a standstill, Belgians being busy at other things than tire building. Prowodnik plans to raise its prices about 10 per cent.

United States Has 1,548,350 Cars

(*Continued from page* 297.)

cars are licensed once every 3 years instead of every year. Louisiana, Mississippi and South Carolina continue to have their automobilsts register with the local authorities, there being no state registration.

Lack of Uniformity

It is to be deeply regretted that there is so little uniformity about the automobile laws in the various states as this aspect of the situation is not only very inconvenient to tourists, but it also renders it very difficult to obtain statistics and especially so in regard to the various classes of vehicles, comparatively few of the states segregating these.

Many Delinquent Licenses

Referring to the table of registrations on page 297, it will be seen that there is apparently a decrease in registration in Georgia, Kentucky, Louisiana, Mississippi, Montana, Oklahoma and Washington. Telegrams to the respective Secretaries of State of Georgia, Montana, Oklahoma and Washington brought out the fact that the apparent decrease is due to delinquent licenses, while in Kentucky the new law is responsible for the lower registration and in Mississippi and Louisiana lower and more accurate estimates have been secured.

Owing to the incomplete registration figures, only twenty-five of the states were able to give information in regard to the number of chauffeurs in the state. Four of these stated that no chauffeurs were registered and the total number of the chauffeurs registered in the other twenty-one states was 271,858.

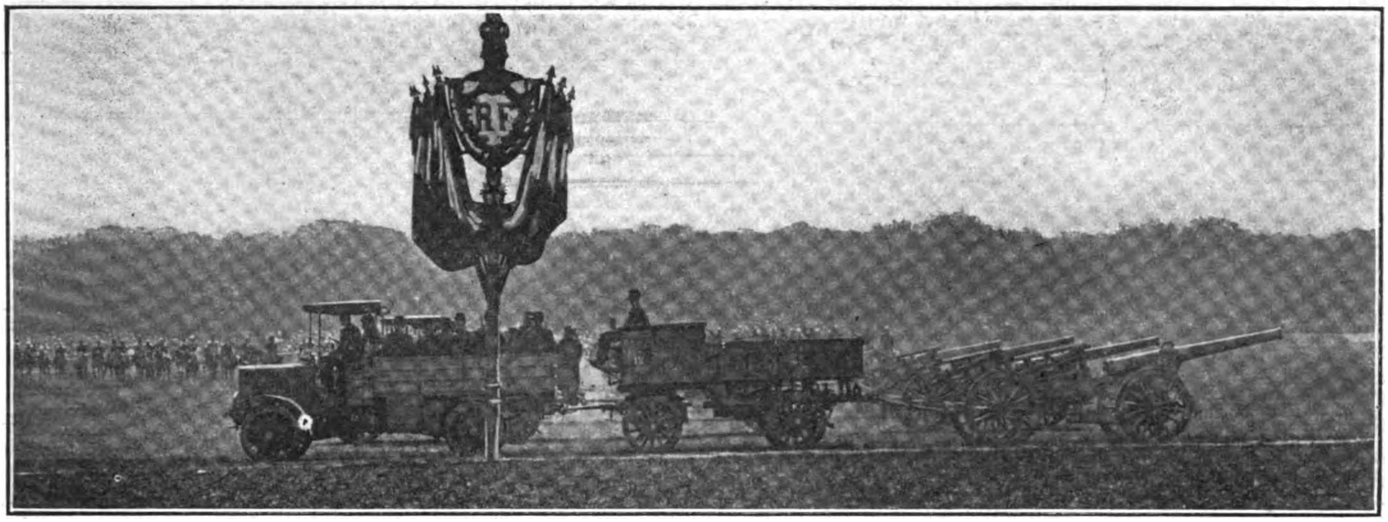
Thirty-four states were able to give the total in fees received, which amounted to $7,812,907, two states having over $1,000,000 income from this source, New York with $1,351,826 and Pennsylvania with $1,067,295.

Of course, the totals in the table on page 297 are very inadequate for the number of gasoline passenger cars and trucks and electric passenger cars and trucks, figures being available in comparatively few of the states. Such as are given, however, are significant.

Pierce Offers 54 Body Types

(*Continued from page* 303.)

ever before. Wire wheels may be secured at an extra cost but the standard cars are fitted with wood wheels having the Johnson patent demountable rims. The extra tires and rims are carried on the running board and this year the Silvertown cord tires will be found as standard equipment. In addition to the actual constructional features of the car all models will be regularly equipped with hand inspection lamps, and a full instrument board which includes the clock, speedometer, odometer, oil and gasoline pressure gauges, voltmeter, ignition and light switches and starter button. Magnetic gasoline tank gauges are now fitted on the tanks. In addition there is the power-driven air pump for inflating tires, a bulb and electric horn, collision bumper, trunk rack, shock absorbers, a supply of oils and grease, extra valve and spring, storm curtains, mud aprons, ventilators, tonneau lamp and in inclosed cars there is an adjustable foot rest, Waltham clock, umbrella holders and everything else that makes for luxury.



Four-wheel drive tractors hauling heavy guns in annual military display at Longchamps

War Injures Only European Trade

Will Not Hurt Commerce with British Oceania or U. S. Territories

WASHINGTON, D. C., Aug. 8—While the European war is sure to cut deep into the foreign motor car trade of this country, government officials here believe that markets in South America, Asia, Oceania, Africa, to say nothing of the noncontiguous territories of the United States, will be productive of much business within the next few months. That the war, if continued for any length of time, will be a serious blow to American motor car makers is conceded by all acquainted with conditions abroad, but government officials charged with the duty of advancing export trade assert that many markets now practically untouched can be made productive if proper means are taken to exploit American cars. Canada, of course, will continue to take many cars and is likely to prove the one best bet in the sale of cars abroad.

At the present time, leaving out Canada, British Oceania is our best customer for motor cars. During 1913 Australia and Tasmania took 2,083 pleasure cars, valued at $1,896,990, and seventeen commercial cars, valued at $23,027; New Zealand took 958 pleasure cars, valued at $990,837, and one commercial car, valued at $1,201. Minor shipments were made to other parts of Oceania, together with more than $200,000 worth of parts.

In South America our best customer is Argentina, which in 1913 took 1,062 pleasure cars, valued at $1,181,735, and thirty-five commercial cars, valued at $78,000. Shipments of parts, not including engines and tires, were valued at $74,138.

Brazil is the second best customer in South America, that country taking last year from this country 987 pleasure cars, valued at $1,035,247, and thirty-six commercial cars, valued at $75,073, and parts to the value of $108,859. Colombia followed with the importation of 110 pleasure cars, valued at $113,334, together with three commercial cars, valued at $6,112, and parts to the value of $18,676.

The Central American states are small buyers, Costa Rica, Guatemala, Honduras, Panama and Salvador, buying only eighty cars in 1913.

Just to show what a ripe field is awaiting American motor car manufacturers in foreign lands, the following quotation from a report sent by Consul General Sammons, at Shanghai, China, is interesting: "The interest in motoring, among both the native and foreign populations, is steadily increasing in Shanghai and other parts of China. The increase in the importation of American cars continues. As far as can be ascertained the total net importation of motor cars for China during 1913 amounted to $359,862, being an increase of $180,676 over the previous year."

In this connection is it also interesting to note that the salary of a Chinese chauffeur, according to Consul General Sammons, is from $15 to $20 a month.

Figures compiled from official records show that during 1913 Europe took 233 commercial cars, valued at $198,277, and 7,555 pleasure cars, valued at $6,044,229. To offset this North America took 554 commercial cars, valued at $1,147,622, and 7,460 pleasure cars, valued at $9,164,078; South America purchased 105 commercial cars, valued at $214,773, and 2,715 pleasure cars, valued at $2,950,432; Asia, 26 commercial cars, valued at $46,698, and 1,631 pleasure cars, valued at $1,418,090; Oceania, 63 commercial cars, valued at $119,437, and 3,573 pleasure cars, valued at $3,481,618; Africa, 12 commercial cars, valued at $10,334, and 1,359 pleasure cars, valued at $1,217,346. Exports of parts to these five grand divisions of the globe aggregated in value $5,240,599 in 1913, of which $1,272,881 went to Europe, $3,259,830 to North America, $275,295 to South America, $105,132 to Asia; $260,779 to Oceania and $66,682 to Africa. In addition more than half a million dollars worth of motor cars and parts were shipped to the noncontiguous territories of the United States during 1913.

A Rim and Tire Standard in Europe

PARIS, July 29—Official announcement will shortly be made by the general secretary of the International Union of Automobile Manufacturers of the general adoption by all European countries of the S. M. M. A. standard for rims and tires. The British standardized millimeter rim was decided upon in June of last year and tolerances adopted in September, 1913. The Society has purchased a complete set of rim-checking templates and printed specifications covering its standard. This British standard was brought before the International Union of Automobile Manufacturers, which comprises the makers in every European country, and after a certain amount of discussion was adopted by them in its entirety. The official notice may go out in a few days, and the result will be to standardize the whole of the pleasure car rims in European countries.

Big Competitions Off in France; War Stops Army Trials

Racing and Touring Calendar Annulled —International Cyclecar Trials Abandoned but Grand Prix de France May Be Run

PARIS, FRANCE, Aug. 1—With threats of a general war in Europe, all automobile demonstrations in France have been cancelled.

The International 6-day trials for cyclecars and motorcycles, which should have been held in the Alps next week, have been indefinitely postponed. President Poincare's official automobile tour through the Alps has been abandoned. The annual trials for army automobile trucks, which has been in progress around Versailles for the past 3 weeks, has been ordered to be stopped, the vehicles still in the competition being accepted as suitable for the government subsidies, and all being ordered to remain at the disposition of the government.

The three races at Le Mans on August 15 and 16 have been kept on the program and will be run if the political situation improves, while the date for receiving entries has been deferred. There are three distinct events: the Grand Prix de France for 4 1-2 liter cars, the motor cycle and cyclecar Grand Prix, and a light car race. It is now certain that neither Delage nor Mercedes will run in the Grand Prix de France; this practically leaves the race in the hands of Peugeot, for their only serious rival is Schneider.

No Curtailment by Continental Motor Co.

DETROIT, MICH., Aug. 10—The Continental Motor Manufacturing Co. denies absolutely that there will be any let up in the activities of the concern pending the European war because of difficulty in obtaining certain alloys and high-grade metals, of which the concern is one of the most extensive users in the world. In fact, the outlook for the business is such that the extensive additions to the plant started some time ago will be pushed along as much as possible. These additions consist in wings to the testing and machine shops, and a large amount of new machinery is being added to the general equipment. From now on the Continental company will also make all the metal stampings used in its various models of motors.

De Palma Arrives with Grand Prix Mercedes

NEW YORK CITY, Aug. 7—Ralph De Palma arrived to-day with one of the Grand Prix Mercedes after an exciting getaway from Germany, because a few hours' delay would probably have prevented him obtaining the machine.

De Palma will drive his new mount at Elgin and possibly at the Vanderbilt and Grand Prize races at the Panama-Pacific international exposition next winter.

If De Palma can win another Vanderbilt cup race, the Vanderbilt trophy will become his permanent property. Should De Palma decide not to drive the Mercedes he may be seen at the wheel of the Vauxhall, which he drove in the Grand Prix on July 4. While he had transmission trouble then, he believes the car's motor to be the most phenomenal he has seen.

British Engineers Just Back from Liege

NEW YORK CITY, Aug. 10—It is of interest to note that on the recent trip of the British Institution of Automobile Engineers to Belgium, Liege was one of the places visited. The Minerva and F N works were inspected, the former concern is a well-known manufacturer of Knight-motored automobiles, while the latter produces automobiles, motorcycles and firearms. It is only known in the United States as the producer of one of the first four-cylinder motorcycles, a large number of these machines having been imported several years ago.

Kelly-Springfield Sells 1,000 Trucks

SPRINGFIELD, O., Aug. 10—One thousand Kelly-Springfield 1-ton trucks have been purchased by the National Pure Water Co., Kansas City, Mo. This tremendous order will be delivered at the rate of 100 per month during 1915.

The National Pure Water Company has the exclusive rights and patents on a new hydro-electric water purifying machine. It is the intention of the company to lease these machines to agents in all sections of the country. When the agency is taken over, a complete outfit, including motor truck, settling tanks, cooling stands, bottles, etc., is sold by the National Pure Water Company. In this way the equipment of every agent will be uniform and the parent company will know that they are properly equipped to handle all business in the right way.

The contract signed by the National Pure Water Company provides not only for delivery of one thousand trucks but they further agree to allow The Kelly-Springfield Motor Truck Company, Springfield, O., to furnish all gasoline driven motor truck equipment which may be purchased.

The trucks are to be uniformly equipped. Each is to have a platform body to carry 54 five-gallon bottles of the pure water.

The chassis will be the standard Kelly-Springfield K-30 with 120-inch wheelbase and 9-foot loading space back of driver's seat.

Rudge Whitworth To Send Manager Here

NEW YORK, Aug. 10—John Pugh, manager of Rudge Whitworth, Ltd., will sail for New York August 19 to visit several factories in the automobile industry. Mr. Pugh has been one of the leading exponents of the wire wheel in Europe.

Ford Price Reductions Rule in Canada

FORD, ONT., Aug. 8—Buyers of Ford cars in Canada are to share in profits from August 1 of this year to August 1 of next year. Prices have been reduced as follows: Touring car now $590, formerly $650; runabout now $540, formerly $600; town car now $840, formerly $900.

Should the Ford company be able to obtain the maximum efficiency in factory production and the minimum cost in the purchasing and sales departments and can reach an output of 300,000 cars between the above dates, and should they reach this production they agree to pay, as the buyer's share, from $40 to $60 per car on or about August 1, 1915, to every retail buyer who purchases a new Ford car between August 1, 1914, and August 1, 1915.

300 Dealers at Jeffery Convention

KENOSHA, WIS., Aug. 6.—Discussions, tests and entertainment occupied the time of 300 dealers attending the annual Jeffery convention this week.

The Jeffery Chesterfield Six was explained in all its details and the dealers were enthusiastic in approving the new model.

Talks were made by L. H. Bill, assistant general manager, and E. S. Jordan, secretary and sales manager. It was emphasized that the Jeffery policy is to share with dealers all fruits of its sales experience as well as engineering practice.

Truck Club To Hold Detroit Convention

NEW YORK CITY, Aug. 12—In response to the general feeling that motor truck interests should get together, the Motor Truck Club of America has plans on foot for a motor truck convention to be held in Detroit on October 7, 8, 9 and 10. Other associations have been invited to join the convention. Yesterday Mr. George H. Duck, president of the club, completed arrangements with the Detroit Bureau of Commerce to hold the meetings in the convention hall of the Cadillac Hotel, which seats 1,000 persons. The Motor Truck Club will have its representative in the office of the Detroit Convention and Tourists' Bureau of the Detroit Bureau of Commerce.

J. Lee Barrett, secretary of the bureau, has been placed in charge of arrangements, accommodations, etc. At a meeting of the trade held yesterday afternoon, the convention was given hearty endorsement and local committees appointed.

S. V. Norton, of the Packard Motor Car Co., was appointed chairman of the general committee; M. L. Pulcher, of the Federal Motor Truck Co., chairman of the finance committee: John H. Thompson, of the Thompson Auto Co., chairman of the dealers' committee; W. D. Anderson, of the Anderson Electric Car Co., chairman of the electric vehicle committee, and R. B. Spencer, of the Denby Motor Truck Co., chairman of the publicity committee. The program is to be arranged by the regular committees of the Motor Truck Club of America.

The tentative program divides the junta into three sections, the first day being manufacturers' day, the second, dealers' day and the third and fourth get-together days.

Wilson Co., Top Makers, To Build Trucks

DETROIT, MICH., Aug. 8—A 1 1-2-ton truck will be placed on the market early in September by the C. J. Wilson Co., automobile tops and trimming manufacturers, located at Warren avenue and Fifteenth street, Detroit. The company, of which C. J. Wilson is president and general manager and Stanley C. Wilson, secretary-treasurer, has no connections with the C. R. Wilson Body Co., also of this city. G. Earl Porter, formerly with the Admiral Motor Truck Co., is the designer of the new truck, and G. A. Freeman, formerly with the Warren Motor Co., has become purchasing agent.

Winton Motor Car Co. Is New Name

CLEVELAND, O., Aug. 10—Papers have been filed with the Secretary of State changing the name of the Winton Motor Carriage Co., of Cleveland, O., to the Winton Motor Car Co.

New Moon Uses 1 Gallon Fuel Each 21 Miles

ST. LOUIS, MO., Aug. 7—A trip of 678 miles in a Moon Four-38, in which one-half gallon of oil was used, was made this week by Chief Engineer Goodspeed of the Moon Motor Car Co., who made a trial run in the new model to Moline, Ill., from St. Louis and return. Goodspeed drove the car 172 miles in two days he was in Moline, showing its paces.

On the trip to Moline an average speed of 20 miles per hour was maintained and the gasoline mileage was 21 miles to the gallon of fuel.

Sparton Claims Horn Patent

JACKSON, MICH., Aug. 11—Editor THE AUTOMOBILE—A case that has been pending in the patent office at Washington for some months in which the Lovell-McConnell Mfg. Co. has been trying to prove that it was the inventor of certain improvements in adjustability of motor-driven horns, has been decided against them. The patent was issued some time since to Wm. Sparks of the Sparks-Withington Co., and in passing on the matter the patent examiner stated that the Klaxon representatives were unable to prove that said Sparks was not the inventor.—Wm. Sparks, general manager Sparks-Withington Co.

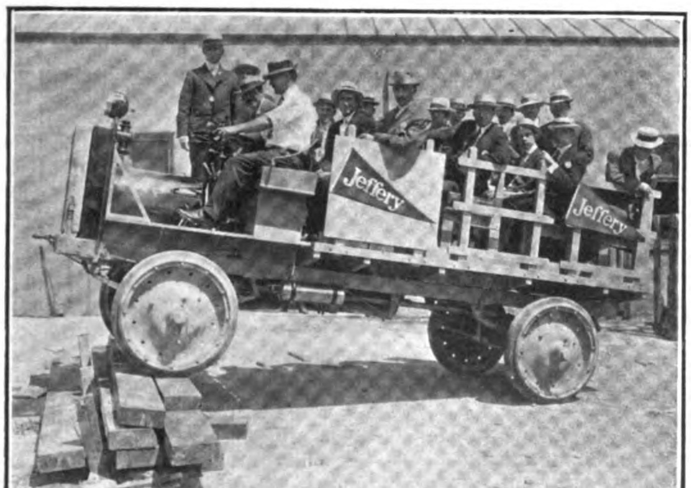
Savage Promoters Under Arrest for Fraud

DETROIT, MICH., Aug. 11—The three chief promoters and officers of the Savage Motor Car Co., which was organized in Detroit last June, to manufacture a four-cylinder light car costing $650, have been arrested by federal officers upon the charge of having used the U. S. mails to defraud. The three officers under arrest are president Delbert H. Cummings, secretary-treasurer-general manager R. W. Fishback and vice-president E. E. Taylor.

According to Detroit and Cincinnati post office inspectors, a large quantity of literature concerning the new Savage 20 car to be, was mailed out from Cincinnati and Chicago to every section of the country, for the purpose of inducing those who might become interested to secure the agency for the car. In order to get the Savage company's agency the customer was required to sign a contract for at least eight cars and make a deposit of $25 per car as an advance payment and a guarantee of the good faith of the depositor. It is further claimed that the agency for certain counties was secured by the payment of $100.

All told, it is claimed by post office inspectors E. E. Fraser of Detroit and Morgan Griswold and H. S. Smith, Cincinnati, that $50,000 cash was thus received by the Savage Motor Car Co., and the arrested officials told the authorities that it was with the money thus received from the prospective dealers that they intended to start the manufacturing of their cars.

The local post office authorities will ask their superior officers in Washington to issue a fraud order against the Savage Motor Car Co., and have the offices on Lafayette avenue placed in charge of government officials.



Two stunts performed by Jeffery four-wheel drive Quad in test last week before a crowd of newspaper men

Storage, Up—Gasoline, Down —New Plan of N. Y. Garagemen

Rents To Be Raised So That Abnormal Profit on Fuel Will Not Have To Be Made

NEW YORK CITY, Aug. 10—If the work of the storage committee which has been working among the garages on New York's West Side is successful prices of storage in that section of the city will be generally advanced September 1. Also, gasoline will be lowered to a point where the price gives the garage a five-cent profit and no more.

The committee is made up of West Side members of the New York Garage Association, and it has been the hope of the whole organization that sometime storage throughout the city might be placed on a paying basis and the profit on gasoline made normal. Up to the present there has been little if any profit in storage, the profit of the business being derived from gasoline, which has been sold at an abnormal profit.

Many independent gasoline stations have recently sprung up in and about the city selling at a small margin, and this has cut into the garage gasoline trade. Garages which insist that patrons buy gasoline in the garage have met opposition. All recognize the advisability of putting storage on a paying basis and making the retail price of gasoline follow the wholesale figure. The agitation is not new but has not been successful up to now.

The present movement was inaugurated on the West Side by Morris Segall, of the Apthorp Garage, who is being aided by William M. Haradon, Royal Garage; H. M. Gibson, Lincoln Square Garage; A. Debblee, Long Acre Garage, and James S. Griffin, International Garage. They have canvassed the West Side and report that sentiment is in favor of the move. A meeting of the West Side garagemen will be held before September 1.

The Royal Garage has informed its patrons that its rates will be adjusted September 1. The proprietor states that he will make this move regardless of whether the others raise or not. August 1 he dropped gasoline from 25 to 20 cents and under the new storage rates will drop it to 18, allowing a five-cent profit.

The proposed rates are in Grades A and B, depending somewhat on the locality and more on the style of building, whether old or modern. Grade A rates would be $40 for open cars and $45 for closed cars; Grade B rates would be $5 lower, $35 and $40.

Walpole Tire Sale Again Postponed

BOSTON, MASS., Aug. 6—Judge Dodge, in the United States District Court, to-day postponed the sale of the Walpole Tire & Rubber Co., which was set for Aug. 12. This action was taken on agreement of all parties concerned as a precautionary measure in view of the existing financial conditions arising out of the war in Europe.

The court has set Aug. 31 for a hearing on the question of fixing another date for the sale.

Market Reports for the Week

Tin and rubber are the only two commodities that were appreciably affected by the war during the week. Rubber is now 8 cents higher. It jumped from $1.07 to $1.15 last Friday and has remained at the latter figure ever since.

Tin is 5 cents higher per hundred pounds, the market price now being 65 cents. No transactions in cottonseed oil or silk are recorded, while all the other products have not changed price to any extent.

Newtone Co. Wins Right To Defend Its Dealers

NEW YORK CITY, Aug. 8—Editor THE AUTOMOBILE—To correct an erroneous impression given by an article in your issue of August 6, where you referred to recent Lovell-McConnell litigation, with the implication that the Lovell-McConnell Co. had succeeded in winning a preliminary skirmish by making the Automobile Supply Manufacturing Co. a defendant, we would advise you that the facts in this matter are just the other way about.

On July 6, the Lovell-McConnell Co. filed a suit against Julius Bindrim, a Brooklyn automobile supply dealer, and by the next day the Automobile Supply Manufacturing Co. had placed the subpoena in the hands of their own patent counsel who succeeded in obtaining a copy of the papers on July 9. The Automobile Supply Manufacturing Co. at once sought to intervene and defend this suit against its dealer, but the Lovell-McConnell Co. refused to consent to the request, and the matter had to be argued in court where the Lovell-McConnell Co.'s counsel again opposed it. Nevertheless, and in spite of the Lovell-McConnell Co.'s opposition, the Automobile Supply Manufacturing Co. succeeded in obtaining from Judge Veeder an order permitting them to intervene and defend the suit.

As correctly set forth by your issue of July 16, page 140, the Hutchison patent in suit is for the "*non*-rigid elastic connection between driver [or cam] and the diaphragm." The Newtones and Newtone Superiors have a *rigid non*-elastic connection and of course are not infringements.—The Automobile Supply Manufacturing Co.

Prosecute Doctors for Using Red Cross Emblem

MILWAUKEE, WIS., Aug. 8—A crusade against the illegal use of the Red Cross emblem on motor cars of physicians, ambulances and other vehicles has been put under way by the United States district attorney at Milwaukee. About 50 prominent physicians and officials of the municipal government are waiting with fear and trembling the result of federal court indictments.

All have pleaded not guilty upon suggestion of the federal judge, although in most every case the defendant was prepared to plead guilty. There being no precedent, Judge F. A. Geiger suggested a not guilty plea to afford time to look up the constitutionality of the act and to decide in what manner fines should be imposed. It is likely that all defendants will finally plead *nolle contendre* and be subjected to nominal fines.

Compromise in McDuffee Contract Suit

DAYTON, O., Aug. 8—Robert Walker and W. E. Strong, receivers for defendant companies in the case of Brown & Sharp Manufacturing Co. *vs.* Dayton Motor Car Co., *et al.*, have filed a petition with the U. S. District Court in Cincinnati, O., authorizing a compromise of the $75,000 breach of contract suit started by the McDuffee Automobile Co. against the Dayton Motor Car Co. in the local common pleas court.

Indianapolis Injunction for Chain Infringement

INDIANAPOLIS, IND., Aug. 7—George F. Kreitlein, doing business under the name of the Guarantee Tire & Rubber Co., Indianapolis, has been permanently enjoined by Judge Francis E. Baker of the United States District Court from infringing patents on a tire grip of which the Weed Chain Tire Grip Co. is the licensee and the Parsons Non-Skid Co., Ltd., a British company, is the holder of the patents.

U. S. L. Receivership Hurts Rubber Works

BUFFALO, N. Y., Aug. 11—Claiming that the recent appointment of receivers for the United States Light & Heating Co. crippled the business of his concern, Elias L. Toy, of Philadelphia, Pa., last Thursday afternoon filed action here in United States district court against the Buffalo Rubber Mfg. Co., asking that a receiver be appointed for that company. Judge Hazel immediately granted the request and John A. Lynch, of Buffalo, was appointed receiver, bond being placed at $2,500. Saturday an answer by the directors of the Buffalo Rubber Mfg. Co. was filed in federal court admitting the allegations charged against them by Elias Toy, of Philadelphia. They replied that the company is insolvent and they approved of the receivership.

The petitioner, president of the rubber company who filed the affadavit accompanying the petition, states that when the United States Light & Heating Co., of Niagara Falls, N. Y., recently went into hands of receivers, the Buffalo Rubber Mfg. Co. was unable to continue the manufacture of rubber because the receivers for the heating company cancelled a large quantity of orders. The complainant claims that the rubber company will be unable to manufacture and market its goods until the heating company again begins operations as usual.

Mr. Toy alleges that the company has numerous creditors in different states and cities. The petitioner's claim consists of $350 for money loaned on a note. He alleges that the company has a floating debt of about $9,000 and many individual claims and notes aggregating $2,000, which are due and unpaid. In urging that a receiver be appointed Mr. Toy alleged that several suits had been brought against the company for collection of obligations and that other proceedings are threatened. The petition also maintains that the property of the defendant in this state is subject to judgment, execution and other proceedings, with the result that unless a receiver were appointed there would be a multiplicity of suits and complicated litigation. The assets of the company, Mr. Toy states, are greatly in excess of the liabilities and with proper care can be conserved and the business again placed on a firm basis.

Overland To Retire 250,000 Preferred Stock

TOLEDO, O., Aug. 10—The Willys-Overland Co., through its New York agent, the Bankers' Trust Co., has sent letters to all holders of Overland $5,000,000 preferred, asking them to set prices on their stock. During the present month $250,000 of preferred stock will be retired, in accordance with a provision of the company's charter.

"The redemption price of our preferred stock is $110 a share," said Royal Scott of the Overland general offices. "The Bankers Trust Co. has been authorized to go into the market and procure the $250,000 of stock that is to be retired. Stockholders will be given a chance to offer their stock at redemption price, or less. If a sufficient amount is not offered voluntarily, redemption of the required amount will be forced. The letters from stockholders will be opened August 25 or thereabout."

Half Rates for 1914 Licenses in California

TACOMA, WASH., Aug. 8—W. R. Ormsby, of the state motor vehicle department of California, has issued the following bulletin, effective Aug. 1:

"The attention of the public is called by the motor vehicle division to the fact that, beginning August 1 and terminating December 31, the fees for the registration of automobiles are one-half the regular fee. Also the fees for the registration as dealers in automobiles are one-half the regular fees.

"For the registration of motor vehicles, owned by or under the control of a manufacturer or dealer in motor vehicles, if such persons operate upon the public highways not more than five automobiles the revised fee is $25, and $5 for each automobile in excess of the five so operated."

Cleveland-Galion Wants To Declare Dividend

CLEVELAND, O., Aug. 10—The Cleveland-Galion Motor Truck Co. has asked authority to pay a second dividend of 15 per cent. to its creditors in a report filed in the Cuyahoga county court. This report also shows receipts and disbursements from April 23 to July 21. A hearing is scheduled for August 19.

Interstate Commission Allows Freight Raise

NEW YORK CITY, Aug. 10—Freight rates for the shipment of automobiles in the Great Lakes district are affected by the final publication of the decision of the Interstate Commerce Commission, allowing "a horizontal 5 per cent. increase in rates."

The increases apply only in the Central Freight Association territory, which lies between Buffalo and Chicago. Shipments to points east of Buffalo will not share in the advance, or through shipments to the Pacific. Part of the 5 per cent. will be allowed on freight for the South, however.

Taking the case of a freight rate which is 50 cents per 100 pounds, the net increase amounts to 5 per cent. which on first-class merchandise brings the figure to 52½ cents. Motor cars, however, are classed at 110 per cent. of first class rates, which brings the figure to 57¾ cents per 100 pounds.

Fifty Miles of Wider Roads Built in Massachusetts in 1914

Whole Mileage of State Is Now 980.37, the Additions Having Lower Crown and Bituminous Binder

BOSTON, MASS, Aug. 8—The annual report of the Massachusetts Highway Commission has been issued containing the facts relative to roads and motor vehicles which interest road builders and motorists. According to it the total length of state highways now completed is 980.37 miles, of which a mileage of about 49.5 was done last year.

There has been expended on these roads since the work was first undertaken just $9,288,143.35. This does not include the money spent by towns and cities.

The report states that for the past 3 years there has been a constant increasing interest on the part of city and town officials to secure good roads, and the commission has extended a great deal of aid to such officials. County officers also have done their share to increase the state mileage.

About $2,690,000 was available for maintenance and constructive work last year and out of this much was accomplished in the way of resurfacing highways, strengthening bridges, etc.

The commission feels that it needs more men for its engineering department for it states, "To increase from $650,000 to more than $3,000,000 for road expenditures in five years, without a corresponding increase in the working force, and to secure good results are certainly worthy achievements for any office or any force."

Building Wider Roads

The commission has continued its policy of making the main roads wider, usually building 18 feet of stone surface instead of 15 feet, which was formerly the standard width. It has also continued to use on such roads some bituminous binder and has been reducing the crown of the road 1 inch to the yard in width, not only to make the road less slippery, but also in order that the traffic will distribute itself over the whole width of the highway. This additional width and bituminous binder which is now necessary increase the cost of construction from 50 to 75 per cent. The 8-hour law and the workingmen's compensation law have also largely increased the cost. The increase in traffic, particularly of motor trucks, is responsible for the increased width and cost of the highways now.

The commission has started experimental work on a sand and clay road in Gay Head under the direction of an engineer from Washington, and if it is found that it will stand up in Winter many more miles will be constructed on the South Shore where there is an abundance of material, and because of the low cost of such highways.

The commission has done work in 222 cities and towns and $287,000 was available for this work. The report states that what were formerly country roads have now become main highways because of the adoption of motor vehicles for business and pleasure and this has been the cause of a big expense for maintenance. Some of the state highways are 20 years old but the average of all is about 10 years. While adequate for some years after they were constructed they are too narrow now in some places, and are wearing out badly in others. It will cost from $8,000 to $10,000 a mile for reconstruction, but the work must be planned far ahead, and be done gradually or in a few years many miles of state highway on the heavily traveled routes will give out and go to pieces. The work should be planned and at least 100 miles a year done from now on so that at the end of 5 years at least 500 miles will be widened and reconstructed. The engineers estimate that at least $3,000,000 is needed for the immediate widening and reconstruction of the through routes.

Some system of uniform traffic counts should be adopted from a formula that would give the weight or damage done by the different kinds of traffic, based on the weight per yard width per year, or per day, so that results may be compared, according to the report.

Some of the facts connected with the automobile department are very interesting. It shows that out of 5,847 persons examined to drive motor vehicles 671 failed. In 1912 of 5,936 examined 347 failed showing that the examiners are more strict apparently, for almost all the failures were on the road test in handling vehicles.

Mulford at Elgin with Peugeot—Entries Now 19

Next Week's Big Road Race Will See the First Constellation of American Stars in Competition—De Palma Arrives from Europe with Grand Prix Mercedes

CHICAGO, Aug. 10—Ralph Mulford with a third Peugeot, the one in which he cleaned up at Galveston and which also was Boillot's mount in the last 500-mile race at Indianapolis, is the nineteenth entrant in the Elgin road races which are booked for August 21-22. The entry is made by the Peugeot Import Co. of New York. Prior to the recording of the Mulford entry Frank Fox nominated the Gray Fox with Howard Wilcox as pilot.

Entries to Elgin close next Saturday but even if no more come in before then, the Chicago Automobile Club already has a field that surpasses anything ever before secured for the Kane county classics. In the way of drivers it has such celebrities as Ralph de Palma, Bob Burman, Barney Oldfield, Spencer Wishart, Ed Pullen, Gil Anderson, Ralph Mulford, Ed Rickenbacher, Harry Grant and Howard Wilcox, while in the way of cars there are three Peugeots, three Stutzes, three Mercers, two Marmons, two Duesenbergs, two Sunbeams, a Mercedes, a Braender Bulldog, Pahys and the Gray Fox. When Moross names the Maxwells with Tetzlaff, Hughes and Carlson, then the list will round out well. It looks as if twenty-five cars would start each day.

Already the drivers are hurrying to Elgin and informal practice now is going on. The Sunbeams, Duesenbergs, This, Marmons and the Dearborn Stutz already are there.

Poor Track, Slow Races at Worcester

WORCESTER, MASS., Aug. 8—The International Racing Club came to the Greendale track to-day and staged a series of races that brought out about 300 people, an attendance that was very disappointing to the promotors of the meet. As no arrangements had been made to put the track in shape, and it was so dusty that even with two cars going at once it was dangerous, the big event of the day, the 25-mile event, was called off because the drivers were afraid to risk their lives. So instead the program was lengthened out into one, two and three-mile events with the same cars. When the races were all over Jack Laviolette had captured five events, Pete Bourque three, Burlingame two and Weldon and Reynolds one each. The summary:

Two miles—Won by Laviolette, Mercer; Weldon, Lozier, second. Time 2:44.

Two miles—Won by Bourque, National; Reynolds, Knox, second. Time 2:40.

Two miles—Won by Weldon, Lozier; Burlingame, Knox, second. Time 2:39.

One mile speed trial—Laviolette, Mercer, 1:17¼; Bourque, National, 1:17½; Reynolds, Knox, 1:32.

Three miles—Won by Burlingame, Knox; Reynolds, Knox, second. Time 4:31.

Two miles—Won by Laviolette, Mercer; Bourque, National, second. Time 2:38.

One mile—Won by Laviolette, Mercer; Bourque, National, second; Weldon, Lozier, third. Time 1:15.

One mile—Won by Bourque, National; Reynolds, Knox, second. Time 1:28.

Two miles—Won by Bourque, National; Weldon, Lozier, second. Time 3:00.

One mile handicap—Won by Laviolette, Mercer; Reynolds, Knox, second. Time 1:18.

Two miles—Won by Burlingame, Knox; Reynolds, Knox, second. Time 2:55.

Three miles—Won by Reynolds, Knox. No time taken.

Lorraine-Dietrich Wins Touring Car Race

PARIS, July 29—Angers has held a 231-mile road race for touring cars only, in which the winner was François Sisz, who drove a Lorraine-Dietrich at an average of 65.6 miles an hour. Although the winning machine carried four passengers and had the touring equipment required under the rules, it is only fair to state that it began life as a pure racer and even took part in one of the French Grand Prix races.

In contrast to the winner, which was a racer disguised as a touring car, there were about a score of others which had genuine touring car chassis equipped as much like racers as the rules would allow.

The Lorraine-Dietrich, which has a piston displacement of about 670 cubic inches, was followed home by a Hispano-Suiza of only 183 cubic inches at an average speed of 58 miles an hour, this being maintained over a course of a difficult, winding nature. Arthur Duray, on a Turcat-Mery, came third a little more than a minute behind the Hispano-Suiza. Fourth place went to a Cottin-Desgouttes, and fifth and sixth places to Chenard-Walcker cars of 3.5 by 5.9 inches bore and stroke. The faster of these two cars averaged a little more than 57 miles an hour.

An interesting performance was that of a little Gregoire of only 2.7 by 5.5 inches bore and stroke which won tenth place at an average of nearly 52 miles an hour. This was a stock car driven by Bignan, the designer of the motor, and was put in at the last moment when the car originally entered had to be withdrawn owing to an accident.

The following is the summary of the race:

CAR	DRIVER	TIME
Lorraine-Dietrich	Sisz	3 31 06
Hispano-Suiza	Antoine	3 58 57
Turcat-Mery	Duray	3 59 39
Cottin-Desgouttes	De Franck	4 00 19
Chenard-Walcker	Glaszmann	4 04 41
Chenard-Walcker	Dauvergne	4 10 51
Aquila-Italiana	Leduc	4 10 52
Nazzaro	Baratteau	4 26 01
Hispano-Suiza	Bara	4 27 06
Gregoire	Bignan	4 37 49
Rolland-Pilain	Sire	4 56 15
Scap	Molet	4 59 54

Brighton Beach Preparing for Labor Day Races

NEW YORK CITY, Aug. 10—Rapid progress is being made with the preparations for the race meet at Brighton Beach on Labor Day. This will be the first speed carnival offered to New Yorkers this year.

It is expected that many of the contenders at Galveston beach and Elgin will be among the starters.

The star event will be a 100-mile race for a $1,000 purse, $500 to the first, $300 to the second, $150 to the third and $50 to the fourth.

Columbus Race Sanction To Sloan Protested

COLUMBUS, O., Aug. 10—The Columbus Automobile Club and the Columbus Auto Trades Association, which combine both the owners and dealers of the city, have protested to the A. A. A. against the granting of a sanction to J. Alex. Sloan, of St. Paul, to hold a two days' race meeting on the track of the Columbus Driving Association August 15 and 16. The sanction had been granted previous to the energetic protest of the local organizations.

Strong pressure is being brought to bear on the A. A. A. to withdraw the sanction. If it is not withdrawn the Columbus Automobile Club and probably the Ohio Automobile Association will withdraw from the A. A. A.

It is claimed that the Columbus track is unsafe for fast racing, which is shown by the records of the 200-mile race in 1913 when two men lost their lives.

Race Celebrities for Minnesota State Fair

MINNEAPOLIS, MINN., Aug. 10—Several well-known race track stars have been retained for automobile days at the Minnesota State Fair, September 7-14. The races will be on the Hamline one-mile dirt track September 12. Prizes aggregate $1,500. Among the entries are Louis Disbrow, Barney Oldfield, Eddie Rickenbacher, Bill Knipper, Johnnie Raimey, Eddie Hearne, Fred Horey and Joe Cleary.

NEW YORK CITY, Aug. 7—In the recent races at Galveston, in which Mulford took ten out of the sixteen events, Rajah spark plugs, made by the Rajah Auto Supply Co., Bloomfield, N. J., were used. One set of plugs lasted the whole meet. It is stated that no attention whatever was given to this part of the equipment.

Durant Vice-President of Monroe Co.

FLINT, MICH., Aug. 7—The election of officers of the Monroe Motor Co., which was organized last week, has taken place. R. F. Monroe is president and general manager; W. C. Durant, vice-president; A. G. Bishop, treasurer; Curtis R. Hathaway, secretary; W. C. Rowles, R. F. Armstrong and A. B. C. Hardy, together with the officers, make up the board of directors.

Factory Miscellany

FORD Enlarges in Canada—A $300,000 addition to the Ford Motor Co.'s plant at Ford City, Ont., will be erected at once, the new section to replace the only remaining old buildings now known as the "old wagon works." The new building will be six stories high and 200 feet square. It will be of reinforced concrete, of the same design as the main building of the plant.

Between 400 and 500 new men will be employed when it is completed, and the floor space of the plant will be increased nearly 50 per cent. The company is at present building assembling factories in Toronto and this city and will start another in London, Ont., before the fall. These plants will have a capacity of 25 cars a day each, and the Ford City plant will supply them with finished parts.

Michigan Brass Plant Moved—The Michigan Brass & Foundry Co., which was purchased recently by capitalists of Battle Creek, Mich., is being moved to the latter city.

1,000 Engers Next Year—President F. C. Enger of the Enger Carriage Co., Cincinnati, O., has been in Detroit for some time for the purpose of getting the necessary material for the building of 1,000 Enger cars for next year.

Equipping Billings & Spencer Plant—The plant of the Columbia Motor Car Co., recently acquired by the Billings & Spencer Co., Hartford, Conn., is being put in order. The first lot of equipment was moved into the building about the first of August.

Argo Executive Offices in Jackson—The New York City office of the Argo Motor Co., Inc., at 7 East Forty-second street will be discontinued August 1. On and after that date the executive offices of the company will be at Jackson, Mich., where the factory is located.

A. O. Smith Co. Has Outing—The 3,000 employees of the A. O. Smith Co., Milwaukee, pressed steel frames and parts, participated in a monster outing with their families at Waukesha Beach on Saturday, August 8. More than 11,000 persons were on the grounds.

Gramm - Bernstein Expanding — The Gramm-Bernstein Manufacturing Co., of Lima, O., maker of motor trucks, will soon start the erection of a large addition to its factory. B. A. Gramm, general manager, says the work will be rushed to completion some time in September.

Ford Building in Cleveland—The contract for the branch factory building for the Ford Motor Co., Detroit, which is located on East 117th street, Cleveland, has been awarded to Morrow Bros., Baltimore, Md. The structure will be 157 by 296 feet and four stories in height. It will be of brick, steel and concrete construction.

Fisher Body to Enlarge—To provide for increasing business, the Fisher Body Company, Detroit, has acquired a five-story building with 100,000 sq. ft. of floor space at Forest and Grandy avenues, for use as an additional unit to its present plants. It is being equipped for automobile body production.

Patent Farm Tractor—Curry and Richmond Dort, two young men living at Westerville, O., have secured patents on a motor driven tractor which they claim will revolutionize farm work. The machine is in the form of a light motor-driven farm tractor embodying different devices which will adapt it to pumping water, grinding feed, cutting wood, churning and other farm work.

Packard Patrols Go 80,188 Miles—The nine Packard automobile patrols which the police department of the city of Detroit is using covered a total of 80,188 miles during the year ending June 24, 1914. The average mileage per patrol was 8,909 miles, while the average daily mileage per vehicle was 24.4 miles. A total of 50,613 runs were made during the year, or an average of 5,623 per car, or over fifteen per day per car.

Ford Increases Minneapolis Plant—The Ford Motor Co. has bought two lots for an addition to its ten-story building at Fifth avenue, N. and Fifth street, which is not yet completed. The additional space gives the company an entire square of land and will enable it to double the size of its $750,000 assembling plant. The lots cost $37,950. For the present the land will be utilized for a side track and to run cars upon.

Mitchell Six Fire Fighter — The Mitchell-Lewis Motor Co., Racine, Wis., last week made delivery of a new type of fire chief's car to the city of El Paso, Tex. The car is built on the Mitchell De Luxe Six chassis as a roadster, and has room for three passengers. Chemical extinguishers, lanterns, ropes and other pieces of small equipment for fire-fighting are ingeniously arranged in and around the car, which is a small fire department in itself and capable of 70 miles per hour with its 4¼ by 7 inch six-cylinder motor.

Automobile Works for New Orleans—Capitalized at $1,000,000, the Southern Automobile & Supply Co. has been organized to establish automobile works at New Orleans. It plans the construction of seven buildings to cover five acres and the installation of machinery to manufacture every part of an automobile, for constructing motor-boats and gasoline engines, etc. The buildings are to be fireproof, and construction bids will be opened about November 15, while the machinery proposals will be opened about December 1.

The Automobile Calendar

Aug. 2-9	Grenoble, Automobile Club of France's 6-Day Motorcycle and Cyclecar Reliability Contest in French Alps.
Aug. 16	Le Mans, France, Automobile Club de la Sarthe's Coupé International Light-Car Race, 1 liter, 400 maximum cylinder area, 350-500 kilos weight.
Aug. 17	Le Mans, France, Auto Club de la Sarthe's Grand Prize de France for 4½ liter cars.
Aug. 21-22	Chicago, Ill., Elgin Road Races, Chicago Automobile Club.
Aug. 23	Auvergne, France, Coupé de l'Auto Race.
Aug. 27	Brooklands Track, England; Annual Automobile Race.
Aug.	Denver, Colo., 650-mile Run, Colorado Springs to Salt Lake City.
Aug.	Russia, Road Race, Coupe de l'Empereur, 2,500 miles.
Sept. 6-7	Brescia, Italy, Auto Club of Italy's 4½-liter Grand Prize.
Sept. 6-7-8	Newark, N. J., Cyclecar Reliability Tour to Atlantic City.
Sept. 7-14	Indianapolis, Ind., Automobile Show, Indianapolis Automobile Trade Assn.
Sept. 9	Corona, Cal., Road Race, Corona Auto Assn.
Sept. 9-11	Convention Paving Brick Mfrs. Assn., Cleveland, O.
Sept. 10	Portsmouth, Eng., Autumn Conference, Institute of Metals.
Sept. 10-15	Berlin, Germany, German 4½-liter race.
Sept. 15-Oct. 11	New York City, Commercial Tercentenary Celebration.
Sept. 26	Brooklands Track, England, Annual Automobile Race.
Sept. 26-Oct. 6	Berlin, Germany, Automobile Show.
Oct.	Philadelphia, Pa., E. V. A. A. Annual Convention.
Oct. 4	St. Louis, Mo., Automobile Show, Auto Manufacturers' and Dealers' Assn.
Oct. 7-17	New York City Electric Vehicle Show, Grand Central Palace.
Oct. 9-Nov. 2	S. A. E. European Trip.
Oct. 16-26	Paris, France, Automobile Salon.
Oct. 17-24	Pittsburgh, Pa., Automobile Show, Auto Dealers Assn., Inc.
Oct. 19, 20, 21	Philadelphia, Pa., Elec. Veh. Assn.'s Convention.
Oct. 19-26	Atlanta, Ga., American Road Congress of the American Highway Assn. and the A. A. A.
Oct. 28-31	Milwaukee, Wis., Convention, Northwestern Road Congress, Auditorium.
Nov.	El Paso, Tex., Phoenix Road Race, El Paso Auto Club.
Nov. 6-14	London, England; Olympia Show.
Nov. 8-9	El Paso to Phoenix, Ariz., Automobile Race.
Nov. 8-11	Shreveport, La., Track Meet, Shreveport Auto Club.
Nov. 15	Paris, France, Kerosene Motor Competition.
Jan. 2-9	New York City, Annual Automobile Show, Grand Central Palace.
Jan. 9-16	Philadelphia Automobile Show.
Jan. 23-30	Chicago, Ill., Automobile Show, First Regiment Armory.

The Week in  the Industry

Motor Men in New Roles

Hogle Leaves Alma—W. M. Hogle has resigned as general sales manager of the Alma Motor Truck Co., Alma, Mich.

Stanley Takes Lewis in Milwaukee—The Stanley Steamer Co., 321 Fourth street, has taken the agency for Lewis cars.

Winter Wizard Electric Representative—The Wizard Electric Lamp Co., San Francisco, Cal., has appointed H. L. Winter its Detroit sales representative.

Overland Has Boston Outing—The annual outing of the men handling Overland cars under the direction of Connell & McKone, of Boston, was held recently near Boston.

Fields Chalmers Assistant Sales Manager—The Chalmers Motor Co. has appointed Jos. Fields, formerly of Fargo, N. D., assistant sales manager, of its Detroit plant.

Gaither Takes Wahl Agency—The Gaither Auto Company, 241 North Fourth street, Columbus, O., has taken the distributing agency for the Wahl in the entire state of Ohio for 1915.

Die Shop in Milwaukee—Edward A. Kickhaefer, of Milwaukee, has organized the Kickhaefer Mfg. Co. and established a shop for the production of dies and stampings at 199-201 Clinton street.

La Fournier Changes—Jack La Fournier, formerly connected with the Vulcan Mfg. Co., will manage a new garage and repair shop, being erected at the corner of State and Erie streets, Painesville, O.

A. T. Mosher Goes to Chalmers—A. T. Mosher, formerly head of the wholesale department of the Nordyke & Marmon Co., has become state representative for the Chalmers Auto Co., distributors in Indiana for the Chalmers and Peerless.

Paige-Detroit Agency in Nyack—The Rockland County Sales Co. has been organized in Nyack, N. Y., to act as Rockland county distributors of the Paige-Detroit. W. C. Beattie, formerly with the Sprague Electric Works, will assume active charge.

Horne Transferred—Charles W. Horne, who traveled in the middle western states for the Gibson Auto Co., has been transferred to Birmingham, Ala. R. M. Beck, who traveled for the same company in Southern territory, has been transferred to southern Illinois.

Girard Wins Promotion—Frank J. Girard, who has been in charge of the Peerless branch at Columbus, Ohio, located at 168 North Fourth street, has been appointed district manager for the Peerless and will make his headquarters in Columbus. He will have all of central and southern Ohio in his territory. A service station with all parts will be maintained at 111 East Lynn street, with R. L. Gardner in charge.

Morse on World Trip—A business trip around the world to investigate the automobile business and its requirements from the American point of view and to look after the business done by its various agents and representatives in foreign countries, is the program mapped out by E. C. Morse, sales manager of the Hudson Motor Car Co., Detroit, who sails this week for South America, and then will go to the other big countries in Asia, Australia, Africa and Europe.

—

Garage and Dealers' Field

M. & F. Sales Absorbs Consumers—The Consumers Tire Co. has been bought out by the M. & F. Sales Co., which has removed from 422 Jefferson street to 701 Wells street. E. N. Ircink, formerly with the Aermore Mfg. Co., Chicago, has become sales manager.

Goodrich Has Toronto Store—The B. F. Goodrich Co., of Akron, O., will be represented in Canada henceforth, for the Diamond Tire brand, by the J. F. Holden Rubber Co., 699 Yonge street, Toronto, which has handled Morgan & Wright and Dominion tires for years.

Electric Tool Co. in Milwaukee—The International Electric Tool Co. has been organized here, Wm. R. Sorgel being president; Wm. H. Gaulke, vice-president and secretary, and E. K. Rundle, treasurer. The concern will make a line of electrical tools for garages, machine shops, foundries.

Brillion Garage Transferred—The Calumet Garage Co., Brillion, Wis., has been purchased by Edward Colvar, of Manitowoc, Wis., and Adolph Valesky, of Collins, Wis., who will continue the business under the style of Brillion Garage. The concern will distribute the Overland in this territory.

Ohio Making Roads—The Ohio Highway Commission on August 4 awarded road improvement contracts in the Buckeye State amounting to $2,629.000, which call for the construction of 178 miles of highways in almost every county of the state. A large part of the work is to be done during the present season.

Modern Garage in Menominee—The Dugas Motor Co., of Menominee, Mich., has purchased a site and will proceed immediately with the erection of a $20,000 garage building at 315 Ogden avenue. It will be a two-story, of liberal dimensions and contain a large repair shop, equipment for which is now being purchased.

Dodge Agent in Connecticut—The Hartford Motor Car Co. is in the process of organization for the purpose of representing the Dodge Bros. car in Hartford, Tolland and Middlesex counties. Charles E. Walker, F. M. Ridler and Ralph A. Barkman, who have been connected with the Pope Mfg. Co., are prime movers in the project.

Big Accessory Store in Superior—The Motorcraft Store, 1716 Broadway, Superior, Wis., is the name of a new establishment opened Aug. 1 by A. C. Eveland & Co. The store carries the largest stock of motor car and cycle accessories, tires, etc., in the northwest. Mr. Eveland formerly was associated with the Kelly Hardware Co., of Duluth, Minn.

Remy Increases Service Stations—The Remy Electric Company, of Anderson, Ind., recently opened new service stations with D. F. Holliday & Co., 344 N. Delaware street, Indianapolis, Ind.; Perry-Mann Electric Co., Columbia, S. C., and Washington Auto Supply Co., Seattle, Wash. In each of these service stations a skilled mechanic is stationed with a full line of parts for Remy equipment.

To Auction Used Cars—Monthly auction sales of used cars are to be held by the Claypool Hotel Garage Co., Indianapolis, the first sale having begun August 8. The monthly sales will continue two or three days. The company is buying used cars throughout Indiana and adjacent states and announces that it will buy only cars that are in good running order. The company plans to provide an outlet for dealers and manufacturers for used cars.

Minneapolis Overland Dealer Building—Bowman & Libby, Inc., distributor for the Overland cars, are in possession of a block of ground on Great Northern trackage which will become the site of a huge warehouse to carry at least 1,500 cars. The building will be three stories, mill construction, with sprinklers. With a double-deck arrangement it will be practically a six-story building. Three hundred feet of railroad trackage will enable the firm to unload seven freight cars at a time. The building will cost $75,000 and will be ready Dec. 1. The firm will concentrate its storage, now in three warehouses, for winter distribution of machines. The building is to be of brick and terra cotta exterior, 100 by 300 feet.

Canadian Cyclecar Ready—The first Canadian company to make an announcement of a completed vehicle is the Welker-Doerr Company, of Berlin, Ont. The machine is a true cyclecar termed the Wel Doer and seats its two passengers side by side with the driver at the right. The wheel base is 100 inches, the tread 36 inches and the weight 500 pounds. The motor is a two-cylinder, air-cooled unit, rated at 9-13 horsepower. Ignition is by Berling dual magneto. Transmission is by friction, with final drive by belt. The frame is of reinforced white ash, on quarter-elliptics.

Baby Rex Made in Edmonton—The first to be manufactured in Edmonton will be the Baby Rex. A company, the directors of which are P. S. Osser, managing director; Charles J. MacMillan, manager, and A. A. Howard, director and secretary-treasurer, has secured incorporation under the name of Rex Motors of Canada, Limited. It is the intention of the company to establish their plant in Norwood. The car they will build is designed on decidedly unique lines, and it has many points of distinction for a light weight car. The engine is of the aeroplane type. It has sixteen horsepower and will develop a speed of from six to sixty miles an hour and in ordinary running will make 45 miles on a gallon of gasoline. There is nothing in the car to freeze, the engine being air-cooled. Its weight is 750 pounds. It is equipped with self starter and wire wheels.

Recent Incorporations in the Automobile Field

AUTOMOBILES AND PARTS

Delaware

DOVER—The Lighthouse Tire Co.; capital, $1,000,000; to manufacture, sell and buy motor cars, tires and accessories.

WILMINGTON—Pittsburgh Motor Car Co.; capital $100,000; to manufacture motor cars and all kinds of motors. Incorporators: J. M. Frere, H. J. Davis and G. Shearer.

Illinois

CHICAGO—Lincoln Motor League; capital, $2,500; to manufacture, repair and deal in motor cars. Incorporators: A. H. Maurer, C. E. Hall and W. A. McGivern.

Indiana

FT. WAYNE—Ft. Wayne Overland Auto Co.; capital, $5,000; to deal in motor cars. Incorporators: James S. Walsh, Thomas F. Gaskins and George H. Zehender.

Massachusetts

BOSTON—Chalmers Motor Co. of Massachusetts; capital, $100,000; to deal in motor cars. Incorporators: J. J. Murray, Boston; J. L. Hermanson, Brookline; and others.

BOSTON—Mohawk Motor Car Co.; capital, $40,000; to deal in motor cars. Incorporators: C. E. Bosworth, Whitman; H. E. Fullam, Lynn; and others.

Michigan

DETROIT—The Western Gear Mfg. Co.; capital, $5,000; to manufacture gears and other motor car parts. Incorporators: John Saunson, Oscar Palm and Victor Palm.

KALAMAZOO—Safety Fire Motor Car Co.; capital, $10,000.

Minnesota

DULUTH—East Wheel Auto Co.; capital, $100,000. Incorporators: N. J. Upham, T. F. Upham and others.

New York

BROOKLYN—Fred S. Phinney,; capital, $5,000; to manufacture cars and accessories, etc. Incorporators: F. S. Phinney, 100 Madison St., Brooklyn; A. N. Phinney, Brooklyn; A. S. Phinney, New York.

BUFFALO—Hudson-Oliver Motor Co.; capital, $15,000; to deal in motor cars and car supplies. Incorporators: E. G. Oliver, George B. Wesley and Charles W. Pooley, all of Buffalo.

BROOKLYN—Classon Garage, Inc.; capital, $3,000. Incorporators: Patrick H. Mulrear, 28 Kosciusko St.; Edw. H. Mulrear and Albert W. Mulrear, both of 862 Bedford Ave., all of Brooklyn, N. Y.

BROOKLYN—Cooper Flexible Transmission Co., Inc.; capital, $160,000; to manufacture transmission appliances for cars, etc. Incorporators: Ben C. Holt, 50 Church St., New York, N. Y.; Minnie Howe and Sidney C. Yeemans, both of 221 Borden Ave., Long Island City, N. Y.

BROOKLYN—Fred S. Phinney, Inc.; capital, $5,000; motor car accessories, etc. Incorporators; Arthur S. Phinney, 108 West 45th St., New York, N. Y.; Fred S. Phinney and A. N. Phinney, both of 190 Madison St., Brooklyn, N. Y.

BROOKLYN—Kruger Bros. & Co., Inc.; capital, $4,000; to repair cars, etc. Incorporators: John Kruger, 209 12th St.; Jas. C. Kruger, 365 56th St., and Jos. Kruger, 254 Prospect Ave., all of Brooklyn, N. Y.

BUFFALO—Meinhard Auto Service Specialties Sundries Supply Co. Incorporators: C. J. Staples, C. H. and T. P. Meinhard, all of Buffalo.

BUFFALO—W. & L. Mfg. Co.; capital, $30,000; to repair motor cars. Incorporators: H. Z. White, 183 West Tupper St.; B. O. Lee and P. W. Lee, all of Buffalo.

HEMPSTEAD—Baker Rim & Auto Supply Co.; capital, $5,000; to conduct a sales agency. Incorporators: H. L. and G. H. Bankney and O. J. Ipsen, both of Garden City, and others.

NEW YORK—Garrett Auto Service Co.; capital, $10,000. Incorporators; H. G. Commons, 210 West 78th St.; R. D. Whiting and W. G. Stahlnecker, all of New York City.

NEW YORK—J. Dolton & Co., Inc.; capital, $900; to repair and store cars. Incorporators: Jack Dolton, Jos. C. Dolton and Wm. N. Plein, all of 354 West 50th St., New York, N. Y.

NEW YORK—Lighthouse Tire Co., Inc.; capital, $5,000; to manufacture and deal in rubber tires for motor cars etc. Incorporators: John McLaren, F. B. Knowlton and S. V. Dowling, all of 154 Nassau St., New York N. Y.

NEW YORK—Otto Gutzmann, Inc.; capital, $12,000. Incorporators: Otto R. Gutzmann and Paula Gutzmann, both of 911 Amsterdam Ave., New York, N. Y., and Martin Beickert, 1876 Broadway, New York, N. Y.

NEW YORK—Riebe Ball Bearing Co., Inc.; capital, $20,000; to manufacture ball bearings and car accessories. Incorporators: Jos. Hever, 77 Essex St., Hackensack, N. J.; Emil M. Lowy and Leo. L. Lowy, both of 920 Prospect Ave., New York, N. Y.

NEW YORK—S. S. Garage Co., Inc.; capital, $5,000. Incorporators: Chas. G. Evans, 233 Broadway; John F. Staiber and Harry B. Stowell, both of 153 West 54th St., all of New York, N. Y.

NEW YORK—Uneeda Tire Filler Co.; capital, $100,000; to manufacture and deal in motor car accessories. Incorporators: M. E. Rosenthal, New York; J. Golden, Brooklyn; T. Bilgn, New York.

SARANAC LAKE—Shelley Tool Co.; capital, $10,000; to deal in motor cars, motorcycles, machinery, etc. Incorporators: Nathan M. John H. and Hattie B. Shelley, all of Saranac Lake.

Ohio

CINCINNATI—Cincinnati Speedway Co.; capital $10,000; to build and operate a motor speedway. Incorporators: W. T. Foley, F. D. Hirst, T. A. Tauwold, Jr., G. A. Ginter and A. H. Morrill.

CLEVELAND—Windemere-Euclid Garage Co.; capital, $10,000. Incorporators: Carl R. Baker, C. F. Taplin, Earl H. Wells, V. M. Harris and E. M. Golding.

CLEVELAND—Fenfar Co.; capital, $10,000; motor car parts. Incorporators: E. W. Farr, C. W. Fenner, F. J. Breeler, Otto Gutzmann, W. E. Ward and C. A. Ebert.

CLEVELAND—The Hudson-Stuyvesant Motor Co.; capital, $25,000; to manufacture motor cars and supplies. Incorporators: F. E. Stuyvesant, Richard L. Kreesen, B. J. Guthery, R. E. Williams and H. M. Hodet.

CLEVELAND—Simplex Distributing Co.; capital, $10,000; to sell motor cars. Incorporators: F. S. McGowan, E. A. Foote, A. R. Manning, Jr., S. Chestnutt and M. N. Job.

PORTSMOUTH—Motor Fuel & Lubricating Co.; capital, $5,000; to deal in motor cars, accessories and supplies.

Washington

SEATTLE—Auto Specialty Co.; capital, $10,000. Incorporators: J. F. Hill, H. M. Kerr and L. Frank Brown.

Wisconsin

MADISON—Star Tire & Rubber Co.; capital, $5,000; to manufacture and deal in tires and rubber goods. Incorporators: J. W. Mort, C. E. Mort and M. M. Mort.

NEW YORK—Whitefield Motor Car Co., Inc.; capital, $175,000. Incorporators: Morgan J. O'Brien, 2 Rector St.; Alan J. Corey, 91 William St., and Dewees Dilworth, 140 Broadway, all of New York, N. Y.

Virginia

RICHMOND—Overland Motor Co.; capital, $5,000 to $20,000; to deal in motor cars. Incorporators: D. P. Browder, O. C. Granger and others, all of Richmond.

GARAGES AND ACCESSORIES

California

LOS ANGELES—The Over-All Roller-Bearing Co.; capital, $500,000. Incorporators: T. W. Starr and others.

Delaware

WILMINGTON—Day Tire Protector Co.; capital, $100,000; to manufacture motor car tires. Incorporators: F. K. Hansell, Philadelphia, Pa.; G. H. B. Martin and E. T. Vennel, both of Camden, N. J.

WILMINGTON—Mogul Starter Co.; capital, $100,000; to manufacture and deal in starting devices for internal combustion engines, etc. Incorporators: W. H. Harris, E. J. Enlers and J. F. Southard, all of Chicago, Ill.

Illinois

CHICAGO—Chicago Gear Co.; from $10,000 to $30,000.

ST. LOUIS, MO—George C. Brinkman Motor Car Co.; from $15,000 to $50,000.

Michigan

DETROIT—Central Oil Co.; capital, $200,000; to deal in gasoline. Incorporators: Roy F. Francis, Otto C. Zoller, Robert J. Morrison and Edward C. Hoffman.

DETROIT—Detroit Starter Co.; capital, $20,000; to manufacture motor car starters and other devices. Incorporators: Alonzo B. Porter, John W. Fitzgerald and F. Joseph Lamb.

DETROIT—General Garage Co.; capital, $5,000. Incorporators: J. Frank and Florence D. Boydell, John C. and Bessie N. B. Wood.

DETROIT—Home Service Co.; capital, $1,200; to deal in motor car supplies. Incorporators: Roland C. Simon, Lorenz Diebel and James E. Dale.

DETROIT—Spranger Rim & Wheel Co.; capital $100,000; to manufacture motor car wheels and rims. Incorporators: N. M. Spranger, Frank Spranger and Clara B. Dettmer.

DETROIT—Western Gear Mfg. Co.; capital, $5,000; to manufacture gears and other motor car parts. Incorporators: John Saunson, Oscar Palm and Victor Palm.

Missouri

KANSAS CITY—Auto Jack & Storage Co.; capital, $25,000. Incorporators: Robert Parker, L. H. Parish and R. E. Stucker.

New Jersey

NEWARK—New Jersey Motor Utilities Co.; capital, $50,000. Incorporators: John McLean, F. B. Knowlton, I. O. Dowling, all of New York, N. Y.

Accessories for the Automobilist

HELICAL Shock Absorber — The Helical Shock Absorber Co., Louisville, Ky., is marketing a device that operates on an entirely new principle and which is very simple and effective. It is shown in Fig. 1.

A steel helical screw passes through and meshes with an internally threaded bronze nut, which is pivotally mounted in a steel ball. This ball in turn forms a universal joint and is attached by an arm which is rigidly fixed under the lower spring clip.

The top of the helical screw is attached to a leather universal joint; and is also rigidly fixed to an arm set under the top spring clips.

These universal joints keep constant alignment and provide for pitching and side lashing of the car. Projecting from the bottom of the ball is a steel tube containing the lubricant; and the up and down movement of the screw automatically feeds the oil needed.

A fluted leather dust cover protects the screw between the two universal joints. This shock absorber offers little or no resistance to the normal up and down movement of the springs; and does not come into positive action until the spring is compressed to the farthest point in either direction, and tends to return suddenly. At the point of sudden reversal of the spring action, the helical screw must also reverse, but it reverses with sufficient attrition to break the shock or the rebound, and the spring again returns normally and without the usual resultant shock. It takes care of these shocks regardless of their rapidity of repetition.

An advantage of the principle used in this shock absorber is its effectiveness under any load. No adjustments are necessary for the load and it is quick and automatic under all conditions. A set of four weighs only 34 pounds.

The device has had an experimental experience of 2 years, and has proven most satisfactory to all users, it is said.

The list price for a set of four Helical Shock Absorbers is $75.00.

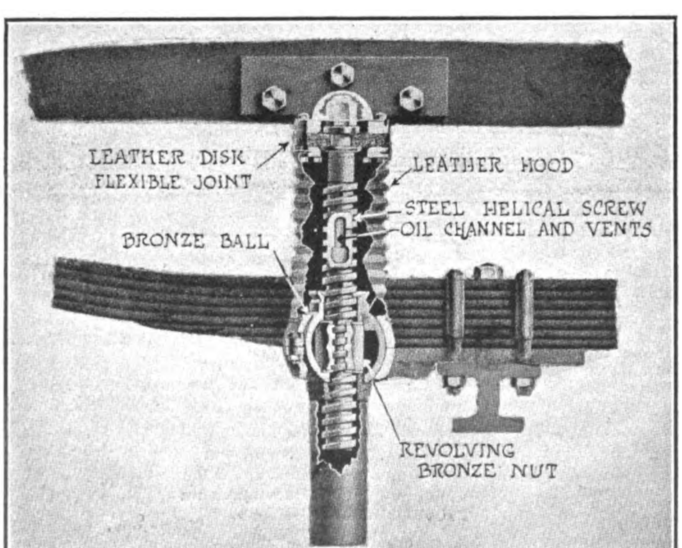

Fig. 1—New shock absorber in which a helical screw is employed

Ajax Electric Headlight Dimmer—A new type of headlight dimmer for electric headlamps has been introduced by the Wanner Mfg. Co., Chicago, called the Ajax and consists of a fluted aluminum cup as shown in Fig. 2, which fits around the base of the bulb. A small brass spring is used to prevent the cup from rattling. The Ajax, which has successfully passed the Chicago inspectors of headlight dimmers, spreads the light over a large area and still gives a good driving light. A pair sells for $1.

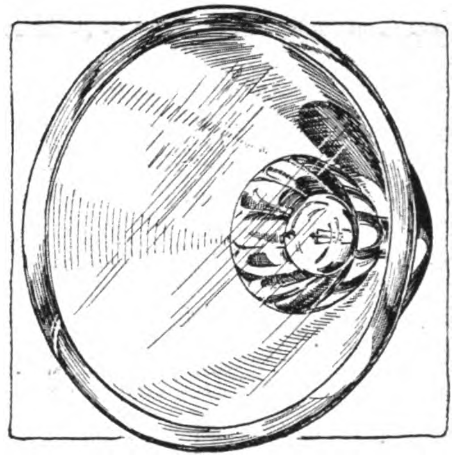

Fig. 2—Ajax headlight dimmer

Gittatit Pliers with Offset Jaws—Instead of making the jaws straight, the H. D. Smith & Co., Plantsville, Conn., has brought out a new design of slip joint pliers, Fig. 3, that are offset so that a pin or nut can be gripped when in a recess or depression.

In pulling cotter pins the heel of the offset often can be used as a lever to draw out the pin.

The tool is well-finished with polished jaws and is 7 inches long over all. The list price is $5.50 per dozen.

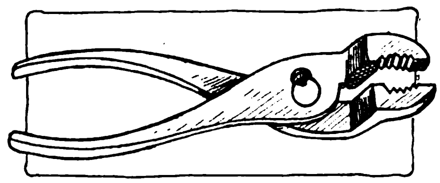

Fig. 3—Gittatit pliers wtih offset jaws

Goodrich Rubber Bucket—A collapsible bucket, Fig. 4, that will stand alone has been brought out by the B. F. Goodrich Co., Akron, O. It holds 2.5 gallons and should be popular with motorists as it folds up into a small space, yet when water is needed for the radiator or when camping along the road it can easily be obtained. The price is $1.50. A feature is the strainer spout. No valves or springs are used in the construction, the water pressure on the rubber being sufficient to hold the bucket in place.

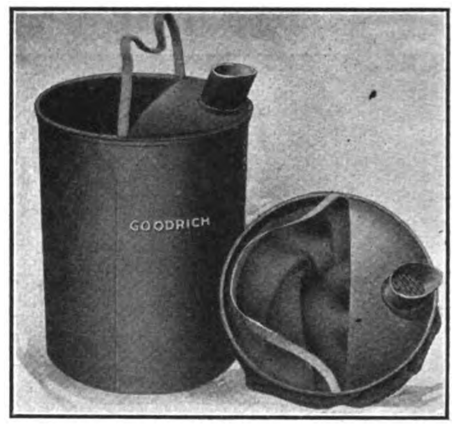

Fig. 4—Goodrich rubber bucket open and closed

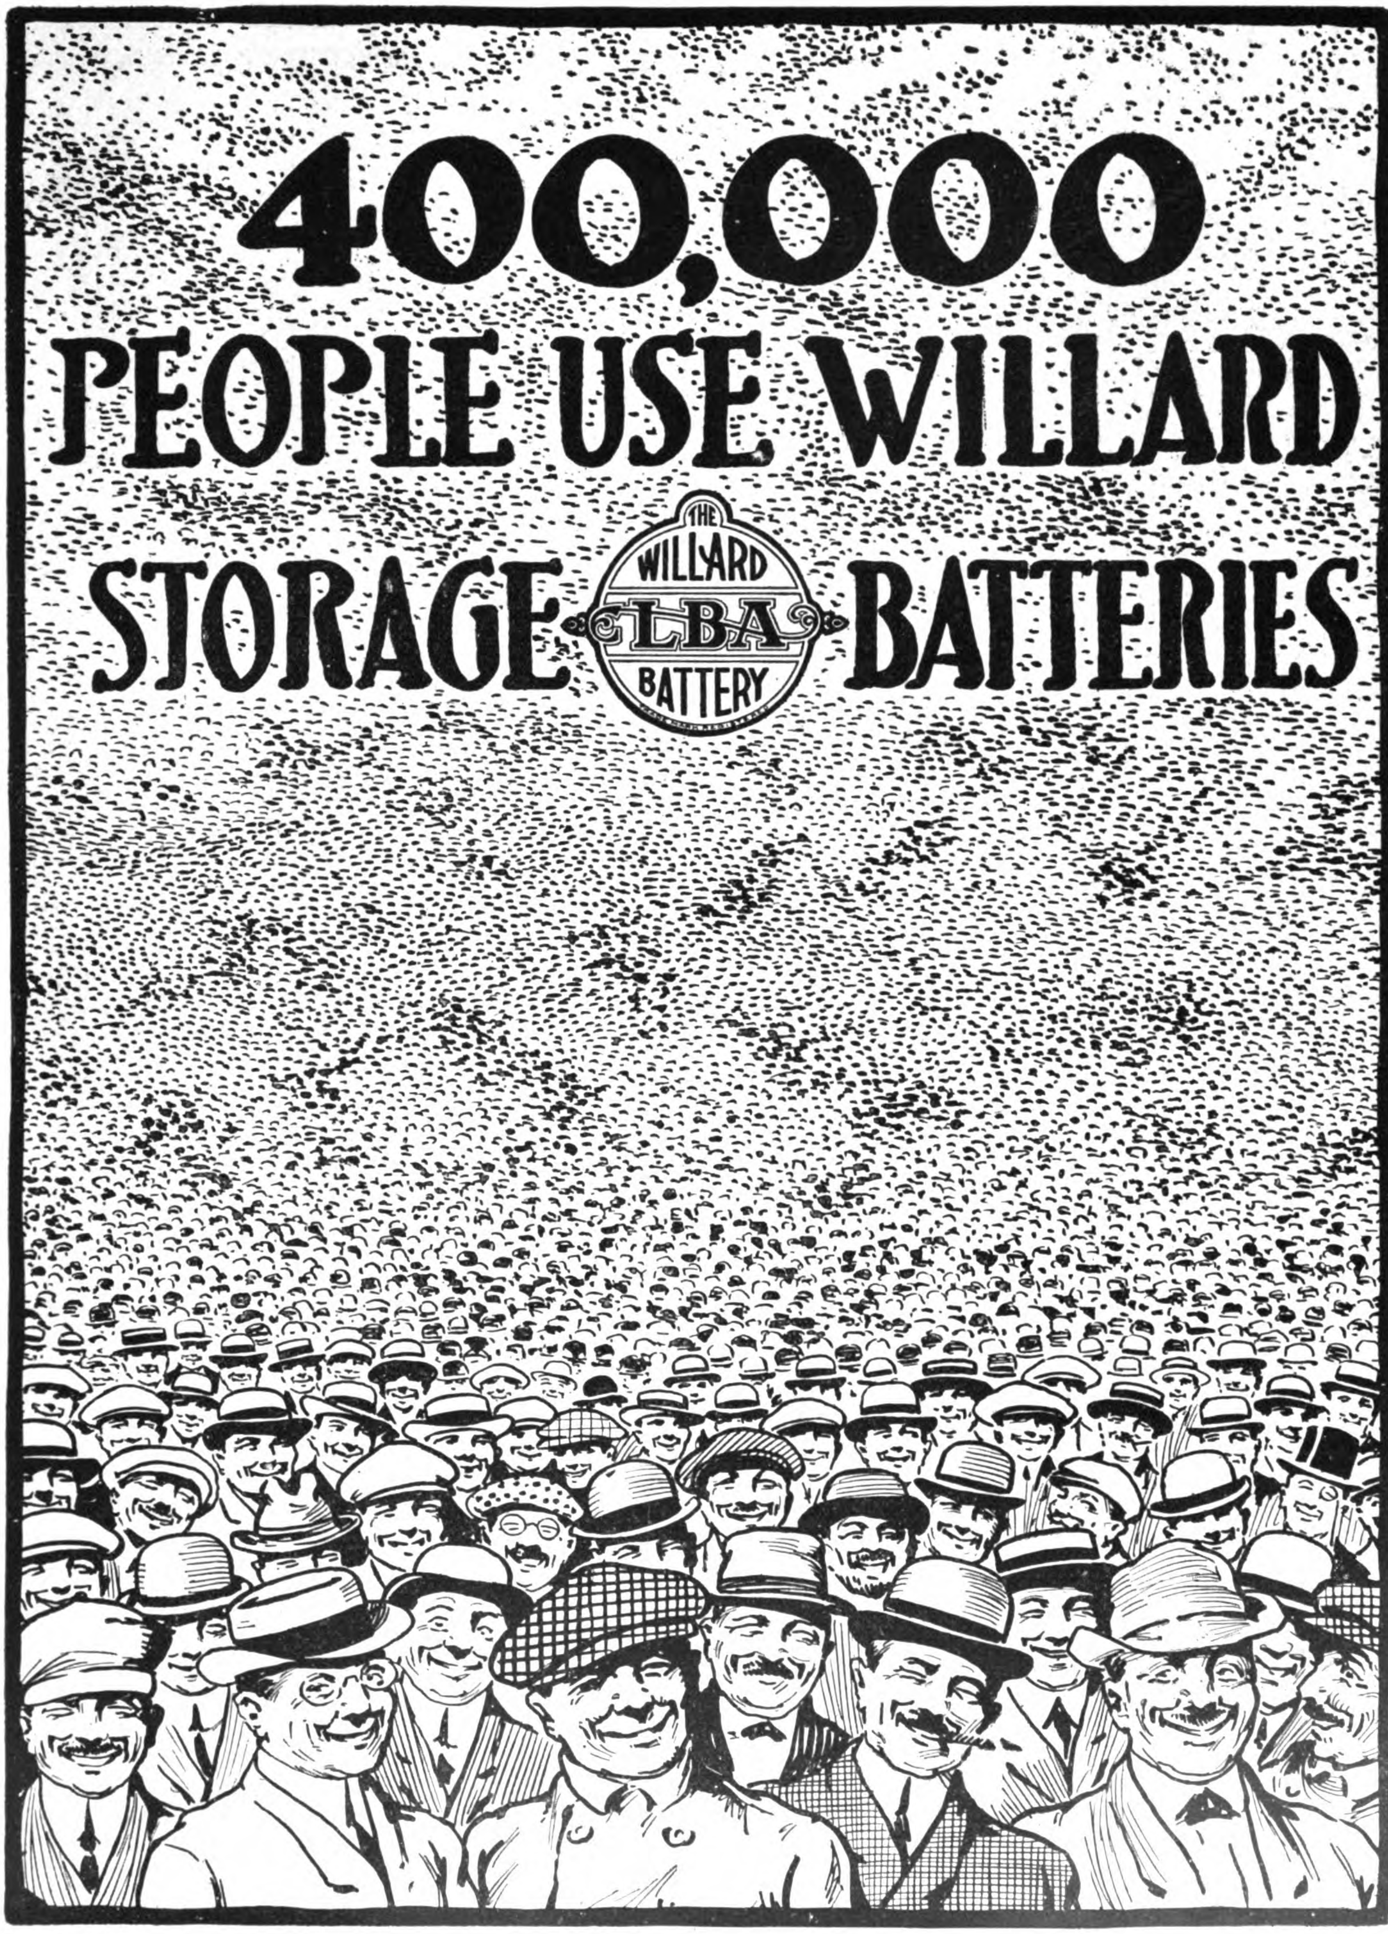
Amco Frictionless Bronze — By means of a new process of combining a large percentage of lead with copper and tin, the American Metal Co., Pittsburgh, Pa., claims to have a bearing metal that is especially adapted for high speed machinery or where the pressures are heavy. It requires no babbitt surface and because of its toughness will wear infinitely longer than the best babbitt metal, it is stated. The composition consists of 30 per cent. lead, 65 per cent. copper and 5 per cent. tin. It is claimed that the large percentage of lead renders this metal as frictionless as any babbitt metal.

Joy-Ride Tire Compound—The Fiber Manufacturing Co., 1649 Court place, Denver, Col., is making a tire compound called Joy-Ride, which is a non-adherent, non-soluble compound, mixed with water, and a small percentage of denatured alcohol to prevent freezing. The selling plan adopted by this firm assures the unqualified satisfaction of the user. The liquid is sold only through its own representatives, at a permanent filling station; a written guarantee is given by the firm to every user that money is refunded if there is loss of air by a puncture to the size of a 20 penny spike.

Generating and Decarbonizing Outfit—Fig. 5 shows a complete generating and decarbonizing outfit, made by the Oxygen Generator Co., Inc., 304 River St., Troy, N. Y. Its operating cost per cylinder is but 14 cents. As the usual charge for cleaning is $1 per cylinder the profit



400,000
PEOPLE USE WILLARD
STORAGE BATTERIES
THE
WILLARD
LBA
BATTERY

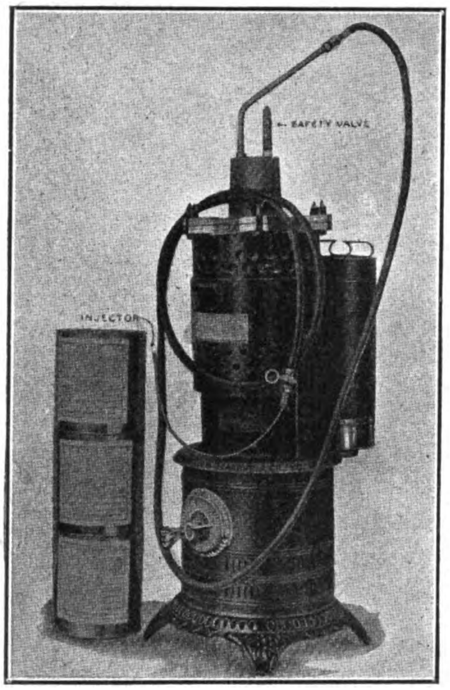


Fig. 5—Oxygen generating and decarbonizing outfit

is large. Therefore, while especially for the garage its low cost puts it within the reach of the individual owner. The complete outfit with enough chemicals to clean 18 cylinders costs but fifteen dollars. The recharge, called Oxygas, is sold in 4 ounce tin containers when bought in lots of six. Each can furnishes enough oxygen to clean 6 cylinders.

Shock Absorbing Cantilever Spring—A new method of springing has been introduced by the Garden City Spring Works, Chicago, under the name of the Shock Absorbing Cantilever spring, Fig. 6, which consists of a cantilever spring and a double coil spring. The rear end of the cantilever is attached in the usual manner as is the fulcrum point, but the front rests upon double coil springs inserted in a bracket. The bracket thrusts downward and this is met with a counter thrust upward and in this way, it is said, frame rail twist is eliminated. The saving in weight due to this construction is another point in its favor and tests by the maker have shown it gives excellent results in checking rebound. When installed on a Ford car the system is slightly changed. In this a steel casting is made to fit the cross member of the frame. The casting has attached to it, at two of its projections, coils spring as shown. The other projections take the cantilever springs. It is said the weight of car bears upon the two coil springs, and the results claimed are easier riding with the elimination of recoil and greater safety in turning. The Ford installation sells for $10.

J. & B. Fuel Saver—The J. & B. Fuel Saver, Fig. 7, is a device designed to automatically control a supplementary air supply with a view to effecting gasoline economy with which other benefits are entailed. It is tubular in shape and is threaded to an angle cock which fits into the intake manifold above the carbureter. At the other end is a hexagon screened nut through which the air is drawn. The operation of the two controlling valves visible through the glass tube is as follows: With the motor running slowly the vacuum in the intake manifold is very high, or, in other words, the suction, because of the throttle being almost closed, is then more intense, and, this being so, the valve with the flat top is drawn to its seat, thus entirely cutting off the supplementary air supply. The closure of this valve is to a degree aided by the pointed valve, which is opposed to it. As the throttle is opened and the motor speed increases so the vacuum in the intake manifold becomes lower and thereby the spring tension which is always being exerted overcomes the suction in the manifold and opens the flat valve wider as the decreasing vacuum allows it to overcome the resistance of the pointed valve, thus allowing a variable supply of air to pass relative to the motor speed. The spring tension exerted in the flat valve is much greater than in the pointed one, and it is because of this and the varying suction in the intake manifold that they open and close in a graduated and practical manner—that is, to be full open at high speed and gradually coming to a positive closure as speed decreases or while coasting along or waiting in traffic. The travel of the flat valve can be restricted and consequently the air supply also by threading the valve with a screw driver in against the short pin which is visible in the center on the right, so making the device standard and adaptable to all motors. The device is nickel plated and sells for $7.

Gemmer Portable Air Compressor—A handy air compressor for garages is the portable model A manufactured by the Gemmer-Detroit Starter Co., Detroit, Mich. It consists of a two-cylinder pump mounted on a 14 by 20-inch steel tank which in turn is placed on 4-inch rubber-tired, swiveled wheels. The pump is driven by a 1-3-horsepower electric motor which is equipped with the necessary cord and socket. A pressure gauge and 14 feet of hose complete the outfit. It takes 25 minutes to fill the tank with air at 175 pounds pressure.

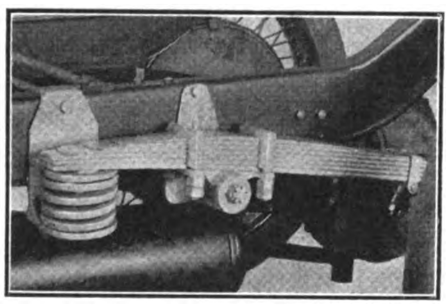

Fig. 6—Shock absorbing cantilever spring

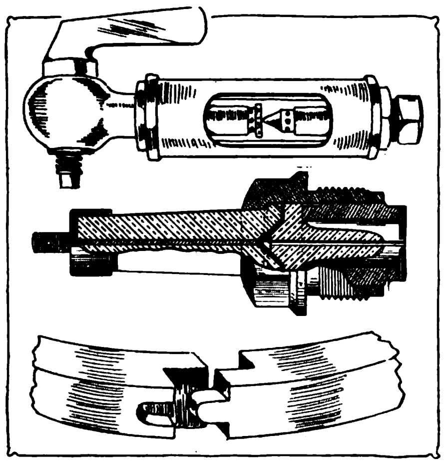

Fig. 7—Top—J. & B. fuel saver
Fig. 8—Middle—Sprung patent spark plug
Fig. 9—Lower—Leektite piston ring

Fig. 10—Everlastingly good terminals

Another type especially designed for sale to the private car owner and for emergency use in garages comprises a two-cylinder pump, connected to a 1-4-horsepower electric motor.

Sprung Patent Spark Plug—A spark plug, Fig. 8, is about to be put on the market which is notable for the reason that the lower half of insulating material and the central electrode are readily detachable from the rest of the plug, so that when the plug becomes fouled or the points burned out, a new unit may be substituted and the plug made as good as new. Another feature is that the plug can be provided with any number of sparking points to suit it for different types of engines. The inventor is A. Sprung, 126 W. 118th street, New York City.

Leektite Piston Ring—By the use of a special joint and a careful process of manufacture the End-Oxy Appliance Co., claims to have a superior piston ring, which is called the Leektite, Fig. 9. The joint is a combination type which is clearly shown in the illustration. The Leektite ring is made of a special grade of gray cast iron, which, after a rough machining, is laid aside for a period to allow thorough seasoning or equalization of the strains set up in the metal during the casting. The ring blanks are then put trough a series of careful machining operations that produces a ring of exact size and shape.

It is stated that the special form of joint used presents a perfectly sealed opening when placed in a cylinder 3-64 inch oversize. The list price for motors of 3.5 to 5-inch bore is $1.50.

Everlastingly Good Terminals—The Emil Grossman Mfg. Co., Brooklyn, N. Y., is offering an assortment of battery terminals, Fig. 10, in a box 10 inches square, that is intended to simplify and facilitate the sale of these articles. There are separate compartments for the various types of terminals and there is a place for everything. The result is a display that looks much neater than an assortment of odd sized boxes. The price is $5.

THE AUTOMOBILE

Russia — An Opportunity

Czar's Empire Is Immense Market for American Cars —Government Favors Imports—Few Russian Cars

By the Late E. P. Batzell

EDITOR'S NOTE.—*Owing to the fact that this article was prepared some time ago by Mr. Batzell, it must be taken as a description of conditions in Russia at the outbreak of the great European war. This war, however, has probably not greatly altered the complexion of affairs in this respect.*

RUSSIA has immense opportunity in store for the general automobile business and other business lines more or less connected with it. The selling and maintenance of cars have the better outlook with them, from the view of profits, than the other activities in this field, notably that of manufacturing whole cars.

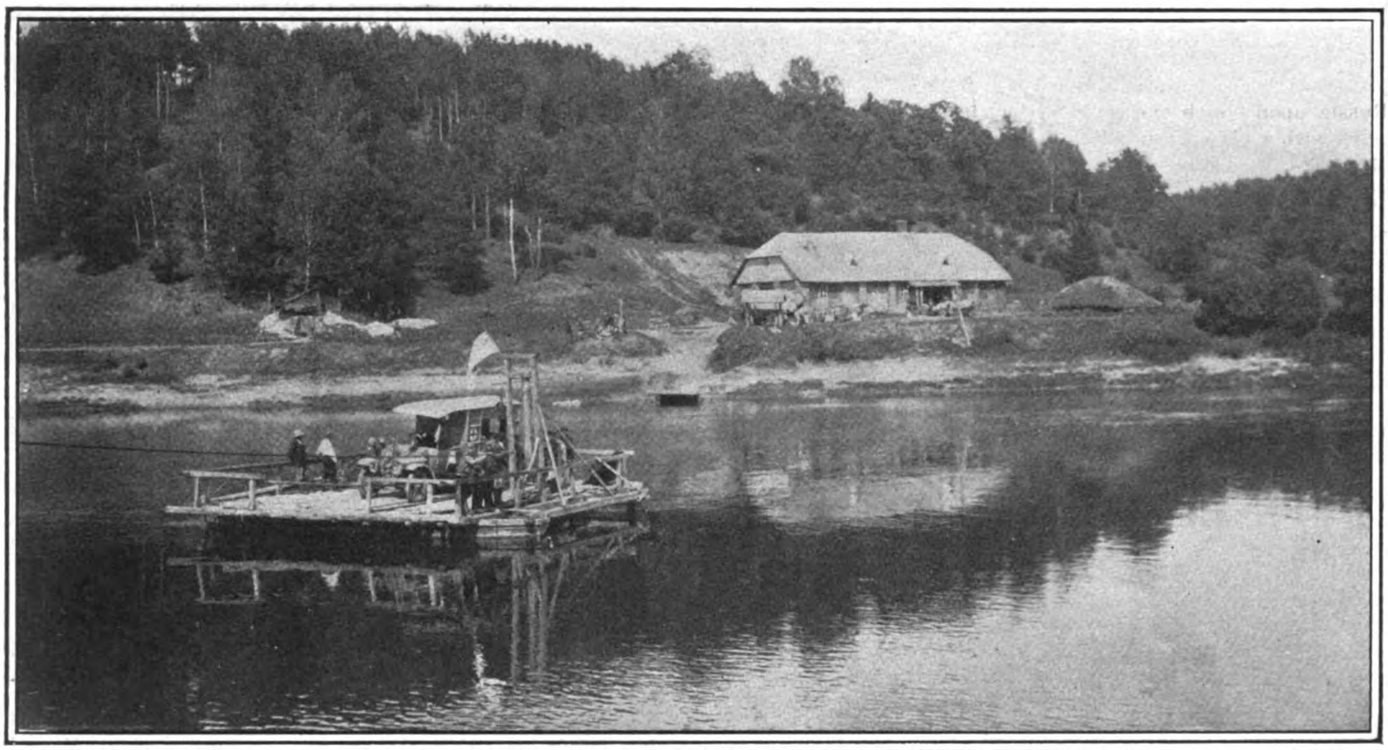
In Russia manufacture is far behind in ability to create strong competition for the imported product on account of the small quantity of cars which can be built with the available facilities. Although the number of establishments actively engaged in building cars is gradually increasing, certain European companies are beginning to open branch plants. Nevertheless it remains very doubtful that the home-built cars ever could form a large proportion of the number of automobiles annually absorbed.

Some very good cars have been and are being built, but only in small numbers of any specific type, each establishment in this line putting out so many different types that this in proportion to the total early output eliminates the possibility of economical quantity production.

The facilities of the factories apparently are directed to satisfy the varying requirements of prospective buyers by building cars for all tastes, almost on the to-order basis. Such a situation is characteristic of all Europe, but it becomes more apparent in Russia because the individual output of the Russian factories is very small, even in proportion to other European countries.

The condition of the general automobile market is to blame for this, because the parties at the head of the concerns fully realize the station occupied and are making efforts to change from their methods of building automobiles to suit the orders which they are apt to get regardless of the requirements in the latter. Instead of hunting buyers with every possible taste, they are endeavoring to concentrate their efforts upon a few models manufactured as economically as possible, for which they may have only certain classes of buyers.

The biggest automobile factory in Russia is the Russo-Baltic. Reducing its number of models and increasing production on a manufacturing principle, this factory expects

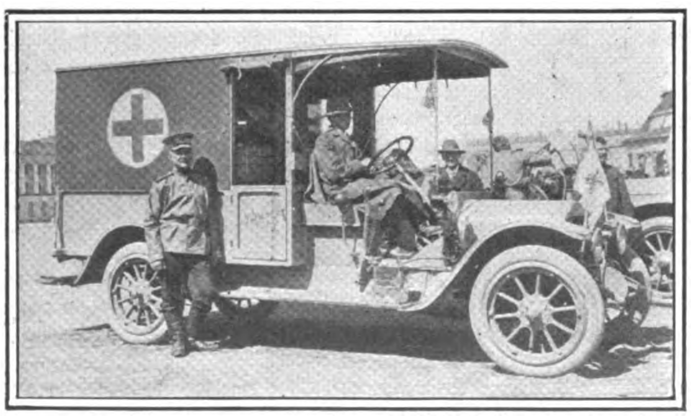


Ferrying one of the White Red Cross ambulances across a river in the Russian army trials

to bring its output from 300 to 1,000 cars per annum. It is well provided to enable it to put through its intentions, as it increases and betters its equipment constantly. It produces good cars, not inferior to the European standard of quality, and has a good reputation. It needs a real sales organization, however. This factory stands on a good road to economical, strictly quantity production, but the influence of the Russian government on a concern so well specialized in this line as the Russo-Baltic is will never allow that. Government orders and subsidies cannot be refused and, on the contrary, they must be solicited, which generally means that the factory must do a large amount of special work in its various departments, thus interfering with the correctly planned production of the regular articles. The situation increases the cost of these regular models, but there are many profits connected with it which more than offset that, really leaving the manufacturer to look upon a government order as a highly profitable business.

Government a Big Buyer

The Russian government is to be considered the biggest individual buyer of automobiles in prospect for the near future and for a long time to come. It is gradually acquiring passenger and commercial vehicles for all kinds of service, and it is also a large prospect for such allied products to the automobile industry as motors for aeronautics, for marine purposes, etc. No doubt so well equipped an automobile factory as the Russo-Baltic will enter similar branch fields sooner or later. The government might offer assistance and subsidies for this purpose, as an inducement for the factory to take up allied lines, the need of which is in view. Naturally, subsidies will be offered on the production of vehicles of special character, for military or civil purposes, together with a high purchase price for them.



White ambulance of the hospital corps as it started in the trials

Those are reasons why a big factory generally in Europe, and particularly in Russia, cannot develop strictly by its own tendency, but falls under the influence of certain factors foreign to it, chiefly in the form of the country's government.

Cars Are Well Built

Such outside influence interferes with the regular manufacturing of articles in quantity, but, on the other hand, the interconnected considerations of business character make one accept it. As mentioned, notwithstanding the harm done in some particulars, there are large profits attached to such orders, both in a direct and indirect way. Executing orders for the government has a big all-around trade value, not merely as an advertisement assisting sales to private parties. At the same time it interferes with the proper development of the regular automobile specialty in the factory, making it more difficult for the latter to catch up with its competitors, especially as long as there is but a slight duty on the imported product.

The Russian-built car was said to be the equal of the up-to-date European, or, rather, of the German-French types. This refers to the construction, the luxury, appearance, etc., whereas they are somewhat cheaper in price and at the same time they are better adapted to the prevailing road conditions in Russia.

They are not so fast as the European cars in general, perhaps on account of their greater weight or lower gear ratio, which is the more probable, as they leave nothing to be desired in regard to pulling ability. It is notable how some duly-recorded performances have been made with cars weighing a great deal more in proportion to the average for that type and motor power. Taking into consideration that at the present there is no road in Russia upon which one could drive with a very large factor of safety at over 50 miles per hour, higher speed being possible only on streets or on special tracks, the present Russian car can give complete satisfaction with all the service reasonably to be expected from it.

White tank wagon as it arrived at Koona in the Russian army trials

Referring to the materials entering into the construction of cars, all the better grades of steel used for the more important parts can be obtained only by importing them.

There is hardly a foundry in Russia which would commercially produce complicated castings like those for the cylinders. But in this respect it is not difficult to catch up with the rest of the world, because there are some very good foundries which thus far have specialized on large parts only, but which could be doing good work for automobile purposes after devoting some little effort to it. Apparently this was unnecessary, as the limited number of cars built could be furnished with many imported rough or finished parts, the available quantity being too small for warranting the creation of a special home industry. This covers merely iron or steel castings, as brass and aluminum are readily obtained there.

Good pressed steel parts and drop forgings are imported, principally on account of the material employed for them, but minor parts of the same kind and inferior material are made at home, sometimes using foreign material.

All the finer accessories are naturally obtained in France and partly in Germany. The motor car bodies are very well executed in Russia, equally to the high-grade European standards of quality and style, better than the European work of minor grade. The coach building art generally is well advanced in Russia, but lack of facilities and initiative have interfered with its taking a merited standing in the world's market.

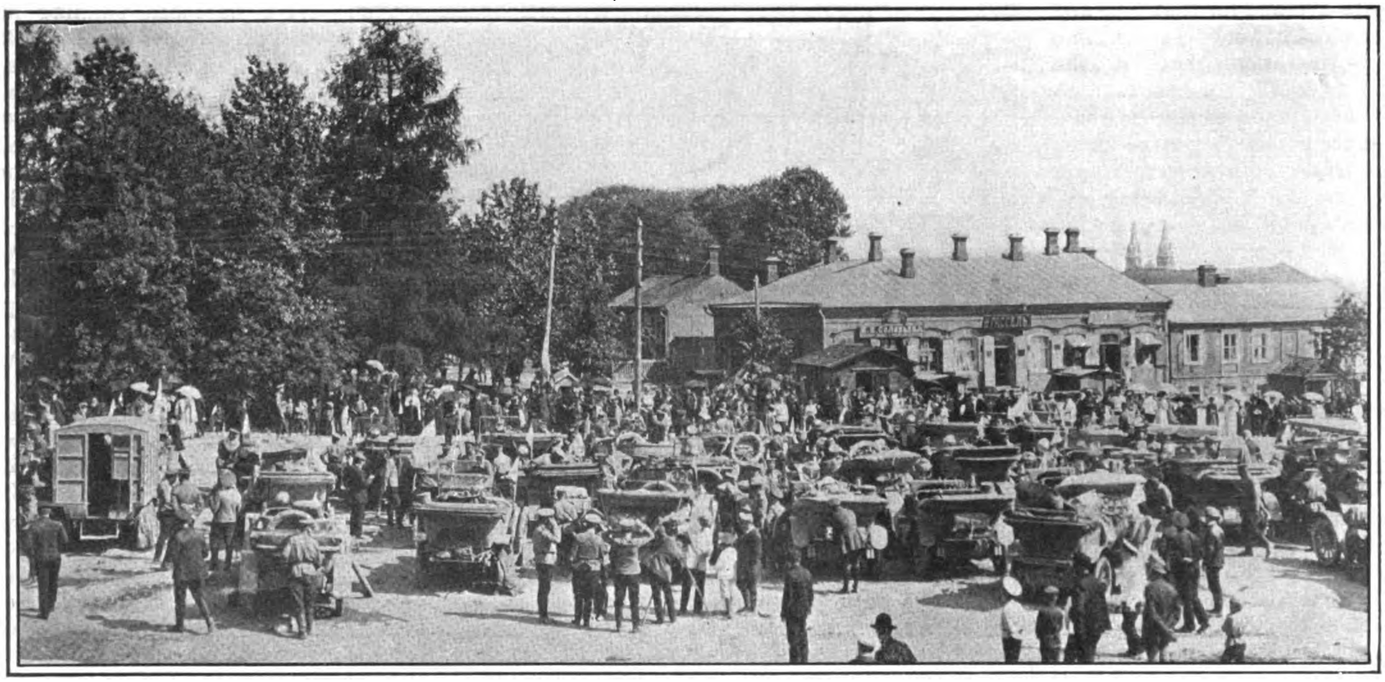
The building of cars is largely done with the help of experienced workingmen imported from other countries. This importation of foreign help is being gradually reduced, approaching that state when there are but a few experts of West European training in each department for the work really requiring specialists. The rest are native workmen. One is practically forced to get capable workmen from outside of the country in the event of an increase of production at the plant, as the available native resources are far from adequate to fulfill the need for experienced help created with any such considerable change from the normally established state of affairs. This is self-evident, when one considers the few automobile concerns which could educate and furnish a reserve of proper help for future needs. Moreover, the number of workingmen employed in any plant is kept much more steady the year around than in the United States, as one does not lay off so frequently as here. Consequently there is much less shifting around and going from one concern to another, leaving hardly anybody to select from when a specialized concern, like the one building automobiles in Russia, suddenly finds itself short in expert help.

Government Encourages Importation

Conditions similar to the related ones are largely responsible in preventing the Russian automobile industry from gaining a good standing in relation to the importation of automobiles. However, the existing policy of the government is to further with great efforts the introduction into the country of the automobile in general without connecting that with protection of this home industry at the same time, which may be expected only at later date when Russia becomes more independent and more supplied with this needed article. Until then the home industry will have to show itself capable to take care in a responsible manner of a great portion of the yearly requirements for automobiles of the various types. Judging from the present standing of this industry and from its prospective development in the near future nothing like the above can be reasonably expected parallel with the growing development of the importation of cars, and thus Russia is left as a great field for the disposal of all kinds of automobiles from the whole world without fear of home competition.

The truth of this prospect is hardly to be doubted, but the

Dragging one of the cars in the Russian army trials up a hill. Note the absence of roads



One of the luncheon stops during the field trials of the Russian army automobiles

rate at which the Russian automobile market will develop in the near future is governed by many circumstances, some of which can be foreseen and some of which can not. The Russian government is a large and steady buyer with great requirements for different passenger, commercial and special types of cars, although the quantities of these purchases grow only gradually, leaving time to get familiar and to try out the bought product. Nevertheless the private public as individuals or as corporations will absorb by far the largest number of vehicles, and it really represents the most attractive side to do business with pursuing merely the object of direct and quick profits.

Interest Is Growing in Automobiling

In Russia the automobile owners, the prospective buyers and the general public are occupying the stage at present, as was characteristic of the United States a few years ago, say 6 or 7. They all are very much interested in automobiles and automobiling; that is, their attention is easily directed toward the latter, but only in a superficial way. At the time quoted here in the United States there were a great many parties who are automobile owners now and who under the circumstances of that time did not think that such a thing could possibly take place because they thought they could not afford a car although they would have liked very much to be able to do so. Gradually people with much smaller means started to buy cars than bought them a few years ago.

Similarly, there is a very large class of Russian medium rich and rich people who are fond of automobiling, but who do not deem themselves to be able to afford to own a car. They take a ride occasionally in a friend's car or in a hired one. They keep in touch lightly with the automobile field by glancing over magazines, etc., but at the same time they do not care to go into a study of technical or commercial details of the cars and of their use, because they cannot assimilate the thought that a large number of them really will buy and use automobiles within the next few years.

All over the world the first stages of the advent of automobiles were connected with abuse of the early and inexperienced automobile owners, especially in regard to their money. It has taken years to educate the American public at large so far that it cannot be cheated easily, that it possesses a certain ability to personally judge more or less correctly things in connection with the upkeep and repair of an automobile. The pleasures of automobiling are enjoyed without the necessity for the continuous services and advice of chauffeurs and other experts. Such ability largely to take care of one's own needs in connection with automobiles has to be looked upon as the prime factor which facilitates the present widespread use of the automobiles in various lines of life and business in the United States. The same factor based on existing conditions in Russia and on the possible progress of the near future cannot promote such a rapid progress there as is witnessed here because the level of public progress in the matters of automobile use and utility is much lower and advances but slowly. This progress is, however, not far behind the western European, the governing conditions being very much alike in all countries there. As yet it is impossible to look upon an automobile otherwise than as an article for the amusement of the richest classes, because the owner is obliged to keep a chauffeur, pay high rates for any repair work or general maintenance and at the same time he has such a slight understanding of all matters pertaining to the keeping and running of his car that any dishonesty he is apt to meet with in this connection is bound to triumph over him.

Maintenance Is High

Even with the low rates for help in Europe, the yearly expenses arising with the maintenance of cars in good order, with the chauffeur and with an average amount of driving, are liable to reach one-half or more of the original purchase price of the car.

Education in automobile matters is what the public interested in them needs the most to become real enthusiasts. A short term of automobile ownership ought to suffice to make the owner so far advanced and proficient that the chauffeur would be reduced from his standing of authoritative expert to merely a servant for driving the car, hauling it around to the house and doing the rest of the common work required. That refers to families who keep but one car, whereas those who can afford to have a number of them of course can have chauffeurs as distinctively specialized as they are now. As a rule, the enthusiastic Russian automobile owners do not hesitate to do some work on the car themselves and, in fact, they know how to see pleasure in this work at times. It is the consciousness of one's incompetence which makes a suffering party out of the average car owner, the more so as they are apparently not trying hard enough to acquire the necessary knowledge.

Owners Must Employ Chauffeurs

It was mentioned that the owners of cars *must* employ chauffeurs, which circumstance somewhat aggravates that situation and interferes with a gradual elimination of it. The chauffeur is as much a necessity there when one has a car as a servant is for the household, however small the latter.

In Russia every city family has at least one servant, even the poorly provided ones, as it is utterly impossible for decent families to get along without them. Naturally then, having a chauffeur to rely upon, should anything happen to the car or should one run across any emergency, the car owner himself is not pressed to gain knowledge and experience so long as he stands all the costs submitted. A novice motorist is especially under the influence of his chauffeur, which prompts the latter to derive some personal benefits, although not always without causing a loss to his employer at the same time. One considers often the chauffeur's advice when selecting a car to be purchased; he buys the materials needed for the car, etc. The owner is left to some extent at his mercy, and certainly the conviction that this is the inevitable state of affairs spreads among the ranks of the would-be automobile buyers who become scared away from the idea of owning a machine which would have to serve particularly well to the benefit of some one else and not for theirs.

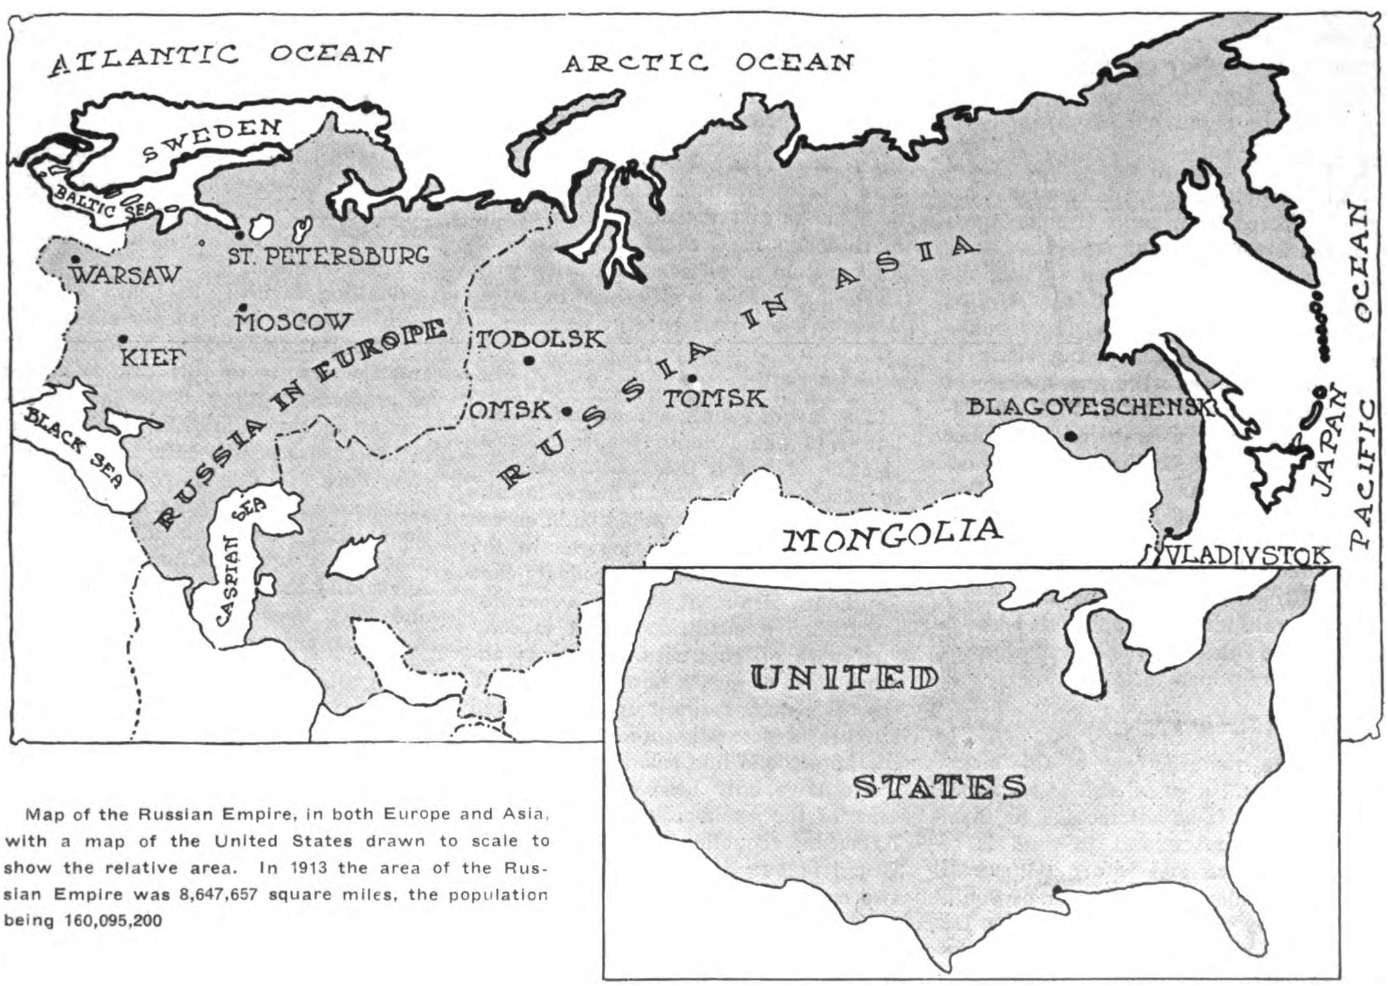
Easy Cheating Anticipated

The writer feels correct in stating, that at present there would have been many more automobiles owned by private parties in Russia for their personal use, if there would be no prospect of easily possible cheating anticipated. Many would have preferred to pay big prices for work and materials really honestly worth it, than to spend less and still be a recipient of articles not up to the value paid for. Similarly, one would rather have an expensive but honest chauffeur, than one with a smaller salary, who will look for compensation on the side. Consequently it seems that to increase the volume of the Russian automobile market, first of all one should lift the standard of the public knowledge and understanding of that field, so as to enable it to handle the whole matter with intelligence. Only then will a great part of the public expect and derive real pleasure from motoring and understand the commercial advantage of cars in many lines of their possible application. One would be free from the conviction, that when going on a trip it is necessary to be prepared to pay a sum largely left to someone else to determine, whereby you are unable to judge anything about this amount. This is almost like letting a man help himself from one's pocket in that the amount he receives depends only on his courteousness.

Dealer Furnishes Chauffeur

It is a correct policy, as adopted by some automobile selling houses, to furnish the chauffeur at least for a certain time to their customers, until the latter become more or less familiar with their machine so that they cannot blame the agents should anything sudden happen, which a new customer would easily look upon as caused by a defect of the machine, whereas it may be not that but the inexpert handling. No doubt that a guarantee covering the maximum rate of cost of upkeep would be very attractive to customers, if such a guarantee could be realized properly, without harming the business of the dealer.

(To be continued).



Map of the Russian Empire, in both Europe and Asia, with a map of the United States drawn to scale to show the relative area. In 1913 the area of the Russian Empire was 8,647,657 square miles, the population being 160,095,200

War Stagnates European Trade

Only Buyers Are War Departments and Only Demand Is for Trucks—Most Factories Are Closed—Hostilities Began in Slack Season

By Special Cable from J. S. Critchley

President of the Institution of Automobile Engineers

LONDON, Eng., Aug. 17—Special Cable—Trade in automobiles, except in vehicles for war purposes, is completely stagnant. It is impossible to state whether the Continental factories are actually doing work, but it is known that very many are closed due to being in the war area or all the labor being drawn to the army. The F N works at Liege, Belgium, are closed, while all the other works in that area, makers of pleasure cars, are simply doing as little as possible and it is doubtful if any progress will be attempted in connection with next season's models. It seems that the war has come at the time when trade is always slack and no attempt will be made to get in supplies until the outlook is more settled. No component parts can be brought into this country from the countries at war, but this only affects the makers of commercial vehicles which are of course in demand. Supplies of most parts can, however, be supplied by the British firms with the exception of cast sheet wheels and magnetos.

To sum up the situation, the only purchasers of automobiles are the various war departments. Most of the purchases are in heavy vehicles. Therefore other makers are practically closing down and not troubling about the supplies. There is a demand only for commercial vehicles to replace those taken for war purposes. All the stocks are depleted and the outputs have been sold for long periods ahead.—J. SIDNEY CRITCHLEY.

South America the Golden Opportunity

By J. Edward Schipper

NEVER was an opportunity more propitiously made than that offered by present circumstances for the development of American trade throughout South America. First, the fair-minded attitude of the United States toward the neighboring republic of Mexico during the trying times in the latter, and the willingness to accept the good offices of the A. B. C. mediators established a state of confidence in the people of this country to a degree higher than ever existed. Following this establishment of confidence there comes the European war which at a single stroke severs the huge southern continent from the source of many of its manufactured supplies and leaves the United States as the logical alternative toward which to turn.

Finance Affected

But the manufacturer of this country cannot fill a vessel full of his product, whether it be automobiles or farm machinery, and expect to send it to South America and return with solid cash. The blow to the finance of South America by the European war was too severe for an instant recovery and the time is not ripe for quick cash deals in those countries. South America has been clearing through English and German banks and the declaration of the moratorium in Great Britain and the interruption of all communication with Berlin has been a severe check to Latin-America's business enterprises.

A Brisk Gain

The law of supply and demand alone, however, would cause the commercial relations between the South American countries and the United States to take on a briskness which would be in excess of anything that has occurred in the past. There are certain products that South America must receive in constant quantities, a condition which is common with all countries. There is another class of goods, however, in which the trade must be built up and fostered by careful promotion and to this class the automobile line belongs.

We have only been getting 10 per cent. of the automobile business in the Argentine republic. Our percentage in Brazil is but little better. Yet these two countries are heavy purchasers of cars and the field is hardly touched. It is also a marked fact that the cars purchased have been of fairly high price and not the cheaper variety, showing that the low-priced car field, which must necessarily exist in every country, has not as yet been opened up to even a small degree.

Banking facilities in South America have naturally been keenly affected by the shock of the sudden European war and the results of this cannot as yet be predicted. Many of the largest exporters in New York City believe that in the future it will be a race between New York and London for the banking supremacy in Latin-America. The National City bank has already established two branches, one in Buenos Ayres and the other in Rio de Janeiro and has opened a complete South American department.

Big Business Soon

There is a strong feeling in the minds of many who have made a study of conditions in South America that the time will not be ripe for big business until the financial atmosphere has had time to clear and that this will take from 2 to 3 months. The American Trade Tour Co. which had chartered the steamship *Kroonland* with the idea of making a special voyage to

South American ports for the purpose of exhibiting and introducing American goods into these countries has become firmly convinced that the original date of sailing, October 14, would find the new territory unprepared for the commercial invasion and has postponed the sailing of the vessel until after the first of the year.

Thus, while the market is there beyond a doubt, still it is a market that must be developed. Credit will have to be given and counter-products bought in this country to give a firm basis of trade. The opportunity is golden but it is a market which must not be rushed but carefully nurtured.

—

U. S. Has Advantage in South America

NEW YORK CITY, Aug. 12—American automobile manufacturers now have the advantage over the European makers in respect to the South American trade. The United States has the chance of its history to dominate in the exportations to the lower continent. Honesty is necessary in all negotiations as there have been evidences of highly developed "Yankee thrift" and "get-rich-quick" sales methods in the past and the Latin Americans are now suspicious of some of the products from the United States.

Argentine Consulate Talks

These points were accentuated in an interview given to a representative of THE AUTOMOBILE today by Ricardo C. Tort, chancellor of the Consulate General of the Argentine Republic.

Said Senor Tort:

"In 1912 the total imports of automobiles in Argentina were 4,281 cars, of which 1,651 were bought from France, 708 from the United States, 627 from Germany, 451 from England, 422 from Italy and 295 from Belgium.

"Since then the imports have increased as financial conditions have improved. The war is a heavy strain on the country now, of course, and it has been necessary to declare a moratarium. Still Argentina is no worse off than other countries.

Profits Were Exorbitant

"It is probable that American imports, prior to the war, were not increasing so satisfactorily inasmuch as a bad feeling was developing toward American cars.

"Cars that sell for $1,000 and under with all equipment in the United States were priced at $2,500 and $3,000 without equipment in Argentina. This is not due to the heavy cost of shipment, which is light. And the duty is only 10 per cent.

"As soon as the Argentine people found out that they were paying the same price for cheap American cars as was quoted them for Panhard-Levasseurs and Isotta-Frischinis and Mercedes, naturally they would not buy the American cars so readily.

Argentine Not Mechanical

"The Argentine people are not mechanically inclined in the slightest degree. Therefore, all have chauffeurs to whom the operation and maintenance of the cars are exclusively left. Practically all of these chauffeurs are Germans, French and Italians, the last two principally. It is natural that when an owner leaves the purchase of a car to his chauffeur, the chauffeur will prefer to buy a car from his own country.

"A further consideration is the fact that practically all of the foreign manufactories keep large stocks of repair parts in Argentina and there is no delay in obtaining supplies. Most of the American makers keep no such supplies and, therefore, when a part breaks there is a delay of months until the part is obtained from the United States.

Chauffeurs' Salaries

"An average chauffeur in Argentina is paid from 200 to 250 pesos a month —from $100 to $125. There are some that get more, and many less. All of them make extras as they take advantage of the mechanical ignorance of their employers and take every chance to have the cars sent to the repair shops, from which they receive tips.

"Because of the revelations that prices for American cars are out of reason and that cheap cars—that seem just as shiny and complete to an Argentine man as the expensive European cars—are being unloaded on them as good grades, the American cars have become somewhat of a joke. They call them 'coffee pots.'

"Out of the 1,651 cars imported into Argentine from France in 1912, I guess that 1,200 of them are Panhard-Levassors. All of them probably are giving good service and their popularity is growing.

America's Chances Good

"The American automobile makers can sell good cars in Argentine. There also is a market for the medium and cheap priced cars, if they advertise them honestly. I don't know if there will be any heavy buying for awhile. I imagine that the people will be conservative with their investments for the time being.

"But the present condition cannot help but profit the American manufacturers."

Willys Sees Big Trade Opportunity

TOLEDO, O., Aug. 14—The European war will act as a positive boost to American business in general and the automobile industry in particular, in the opinion of John N. Willys, president of the Willys-Overland Co. and second largest manufacturer of automobiles in the world, who expresses his views in a cablegram from London, Eng. For 2 months Mr. Willys has been making a study of conditions in Europe at close range and is thoroughly in touch with the situation:

"The English are not slow to see the great opportunities for trade extension given to the United States by recent events," writes Mr. Willys. "Sir George Parish, England's foremost financial writer, declares that the war will bring great wealth to American industries and an economic benefit to the people of the United States.

"The call for army reserves throughout Europe has completely demoralized the industries on this side of the Atlantic. Many of the largest automobile factories have practically been unmanned. Only a very small number of automobiles will be built in Europe until there is a cessation of hostilities.

"In the meanwhile the entire field will be open to the American motor car manufacturers. There may be some difficulty in shipping cars to European ports as they may be declared contraband goods, but the rest of the civilized world will be free from European competition and is America's for the taking. And once the people who have heretofore bought automobiles of foreign manufacture discover the superiority of American cars, Europe will never regain the field she has lost."

Joy Sends "Cheer Up" Telegram Broadcast

DETROIT, MICH., Aug. 14—President Henry B. Joy, of the Packard Motor Car Co., who was appointed a director in the Federal Reserve Bank, of Chicago, is confident that notwithstanding the European war and the momentary disturbance this condition caused throughout the United States, the future looks bright here in America and that there is no need of worry as to business. As an evidence of his conviction in the matter President Joy sent the following telegram to every Packard dealer in the United States:

"Business and banking conditions improved wonderfully since Wednesday. Reported normal again here by Detroit bankers. We feel no apprehension as to future business conditions. The war scare is largely over. International ocean traffic will be improved daily. Nations which have been consumers of Europe's vast exports must now naturally become patrons of America. Post this on your bulletin board."

—

LONDON, ENG., Aug. 17—The war department of Austria has bought all the tires from the Goodyear stock in Vienna, according to the London manager.

The Transcontinental Saxon's Trip

Far from a Joy Ride—Lincoln Highway Progress Remarkable, But Roads Are Still Poor in Many Sections

By M. A. Croker and Fred Wilkins
Pilots of the Coast-to-Coast Saxon

ANYONE who thinks of the Lincoln Highway as a finely-paved road stretching from one edge of the nation to the other and offering ideal conditions for touring all the way, has a mistaken impression.

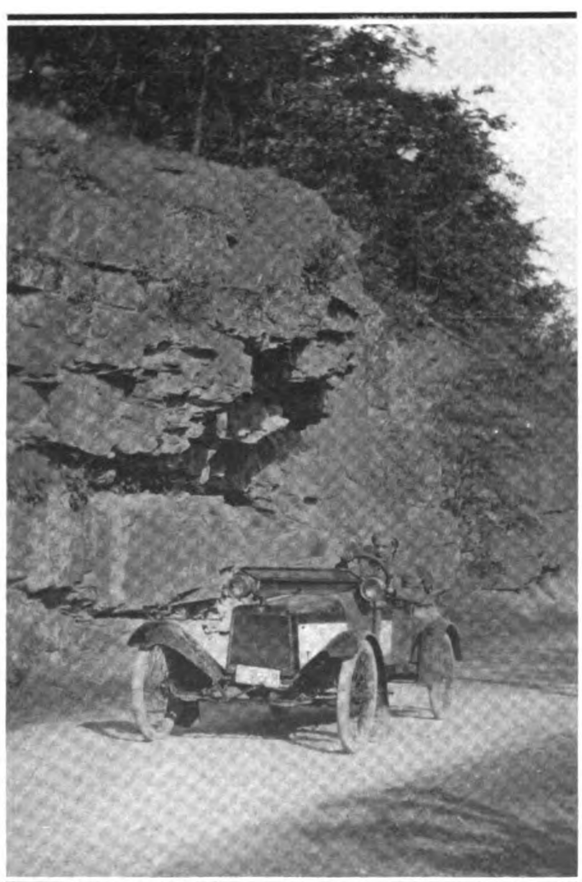
Some day driving over it from coast to coast will be in the nature of a joy ride. The wonders that have been wrought by its sponsors indicate that. But great roads are not built in a day or a month or a year. Considering the comparatively brief time since the Highway was first projected, the progress has been truly remarkable.

By next year even more mighty things will be accomplished, and it is our opinion that fully 2,500 motorists will journey to the Exposition on the coast by motor car instead of using the railroad as many of them undoubtedly would do but for the Lincoln Highway.

At the same time, as we stated at the outset, to cross the continent over the Lincoln Highway in its present state is far from being a joy ride, and we ought to know, for we made the trip in a Saxon car, setting out from New York on June 4 and arriving in San Francisco on July 4. This car was the first ever to go the full distance of the Highway on a continuous trip and the first small car ever to cross the continent over any road whatever.

In our opinion this trip did much to show the progress that has been made in the art of building automobiles. It showed that the transcontinental journey is not for large or even medium sized cars alone, but is possible easily for light cars. It serves to correct an impression that the small car is practical only for city driving. For, as will be seen from the experiences we met with, a small car may not only get over boulevarded roads, but may climb the steepest hills, plow through the deepest mud and sand and go over the roughest roads—often even better than large cars. This is interesting incidentally from the fact that we all recall how only a few years ago, even owners of the heaviest cars would hardly have dared to attempt such an arduous journey as this.

It is worthy of mention, too, that the Saxon which made this trip was not a new car, but the same vehicle which previously ran 135 miles a day in a test lasting 30 days. This test—4,050 miles—was equivalent to the service a car gets in a year in the hands of the average car owner.



Lincoln Highway Saxon amid picturesque surroundings in Western Illinois near the Mississippi

The Lincoln Highway when completed will be 3,389 miles long. Detours, however, due to repairs on the road, washouts and several trips off the main route and back again at the request of dealers who planned receptions—these brought our total mileage up to 3,873 miles. We were on the road 30 days, the actual running time was 278 hours, and the average distance was 129.1 miles a day. The highest day's run was 186 miles. The car showed unusual economy, averaging 30 miles to the gallon of gasoline.

We found interest in the Lincoln Highway and in this run at a high pitch all along the way. Motorists were convinced that this way, when completed, is going to be a boon to humanity. At many towns escort parties came out to meet us and then chased back ahead of us to tell the people in their communities the car was coming.

Road Well Marked

As for the Lincoln Highway marking it was excellent along the road, but we found some difficulty at times getting out of the larger cities because there was no way of telling which road would put us on the Highway. To add to our difficulties we were forced to contend with many road boosting enthusiasts who sought to have us use the roads they were boosting in preference to the Lincoln Highway.

With further reference to the excellent Lincoln Highway marking, even in the sparsely populated regions of the far west where one meets with no signs of habitation, the Lincoln Highway Association has marked the road by means of small pipes stuck in the ground at the side of the road.

Hotel accommodations are far improved over what they have been. The hotels everywhere appeared anxious for the trade of automobilists, many of them having garages in connection. They were always ready to give the best of service—in contrast to their apathy toward motorists only a few years back.

Details of the Trip

When we started from New York for the coast on June 4th, after dipping the rear wheels of the Transcontinental Saxon in the waters of the Atlantic Ocean, we were, of course, confident that the car would reach the Pacific on July 4th—on schedule time.

However, that does not mean that the 3,873 mile trip—that was the actual distance covered by the Saxon—was a pleasure jaunt all the way. No coast-to-coast run is. Neither does it mean that we were always certain of reaching our destination on time. For there is an element of uncertainty due to bad weather, washouts, cloudbursts, the making of new roads which necessitate detours, and all the other factors beyond control of a car or its drivers.

The little Saxon climbing a steep grade in Iowa. Some of the stiffest climbs on the route were encountered in this locality

From the time we passed beyond the Alleghanies and easily negotiated all the long grades—many of them 10 per cent.—our confidence increased. For it was in the crossing of the Alleghanies that the car first proved its dependability by requiring not one additional drop of water in the radiator. It took every hill easily and surely.

Then came the tests through the sands of Ohio and Indiana. These did not balk the coast-to-coast car, although in spots the roads would have stalled many a heavier car.

Really Bad Roads

It was west of Dixon, Illinois, that we began to realize what really bad roads meant. Here we ran into a rainstorm which lasted two days and transformed the roads into an almost indescribable condition. We had to contend with these roads all through western Illinois and eastern Iowa. Just plain mud would not have been so bad, but it was not just plain mud. It was gumbo, and only one who has actually driven through gumbo during or after a heavy rain can appreciate what it is, how it clings to the wheel like glue, is thrown in masses and packs in so thick between the wheels and fenders that it has to be shoveled out. All this is apart from the fact that in driving over such roads low speed has to be used constantly.

To add to the difficulties we struck a new graded road beyond Cedar Rapids, where the gumbo had been taken from the sides and piled up at the crown of the road. Thus, in order to keep on the road, there was no alternative except to drive right through these piles of gumbo which often came up above the front axle. Even at that, there was the danger at times of running into a ditch, particularly if an attempt was made to travel along on high because of the slippery surface of the rain-soaked roads.

In venturing beyond Cedar Rapids we ran across seven cars that were forced to turn back and two that were stuck in the mud. We had to go into a ditch to get by these cars. Beyond that we saw no signs of man, vehicle or beast on the roads, and 30 miles west of Cedar Rapids we, ourselves, became convinced, after the Saxon had gone farther through these awful conditions than any other vehicle, that the roads were impassable. It was then that we turned back and stayed in Cedar Rapids until the rain had abated. No one ventured out during this time.

Gumbo mud does not change back into a favorable road for touring in an instant. Consequently, when we sallied forth from Cedar Rapids the second time we had to continue over more bad roads into Boone, Iowa—roads that had been put in this condition by the rains and had not been packed down.

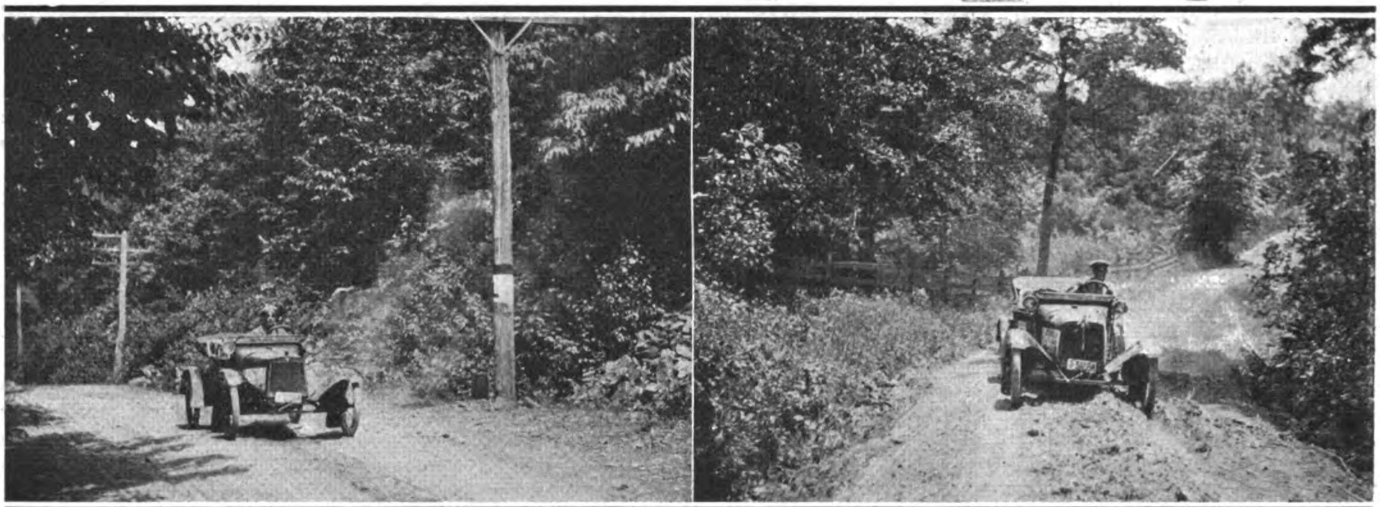
Here we started to hit the hills and we kept on finding it necessary to take hills frequently all the rest of the way to San Francisco.

At Omaha we met with a typically enthusiastic reception. The car was put in the show windows and attracted a lot of attention from passersby and those who went in to look at it.

In our run from Omaha to Grand Island—especially that section between Columbus, Nebraska, and G and Island—we encountered a cloudburst that washed out roads and had a similar effect on bridges. We found the Wood River swollen. The conditions we experienced may be imagined when it is added that the Lincoln Highway is crossed by the Wood River seventeen times. At one point things were so bad there was nothing to do but make a detour in order to progress.

From Grand Island to Gothenburg we struck fairly good

Right—Rough going in Western Nebraska. Some of the Nebraska roads are very good, though most of these are in the eastern part of the state. Left—The washout illustrated was encountered by the coast-to-coast Saxon on the road near Gibbons, Ia. It was the result of 2 days' continuous rain



Left—The Transcontinental Saxon among the hills near Council Bluffs, Ia. Right—A bad spot near Clinton, Ia., through which the Lincoln Highway Saxon pulled in its transcontinental run

roads until another detour was necessitated because of floods caused by the North Platte River and by the work being done in other vicinities in grading the roads. At Gibbons, Neb., the car made its way through roads that were veritable rivers, the water coming up to the radiator.

Beyond this point weather conditions changed. So did road conditions, but we cannot say that they were improved. Running into North Platte we encountered 22 miles of solid sand through which the Saxon blazed a trail—where there were no roads and where the only guide was a railroad track by the side of which we drove.

At Kearney, Neb. we passed a famous half-way post. It had required but 12 days of running time with an average of 10 hours each day to reach this point.

A By-Trip to Denver

Guided by nothing but wagon tracks, we drove from Grand Island to Cheyenne, where we arrived the next day at noon. A great reception was awaiting in Denver so we ran over there, a distance of 110 miles, which was made in 5 1-2 hours through the rain. From there, we retraced our steps back to Cheyenne and continued westward through Wyoming to Laramie and Wamsutter.

Going through Wyoming in one respect at least is like traveling across gumbo roads in Iowa. That is to say, one has actually to make the journey in order to appreciate fully just what the conditions are. The roads, so-called, are simply a succession of deep ruts with high centers, with the frequent occurrence of steep-sided gulleys. To cross these gulleys it is necessary to get a good running start, for the climb out of each gulley is made with the car in an almost vertical position. We found the state of Wyoming the least improved as to roads of any of the states we went through. It is going to be a big job to transform these primitive roads into good nes.

From Laramie to Elk Mountain, a distance of 86 miles, we opened and closed twenty-one gates on ranches through which we passed. There were no roads through this stretch. The steepest mountain climb up to this point was encountered near Elk Mountain. This summit rises to an elevation of 8,247 feet.

We had our first taste of desert country after leaving the town of Granger, Wyoming, which is on the edge of the Red Desert. Here the only excuse for a road was an old abandoned railroad grade which was extremely rocky and rough. By 2 o'clock in the afternoon, however, we had reached Evanston, Wyo., a distance of 127 miles, and just beyond this point we crossed the line into Utah, reaching Salt Lake City over more rough roads by way of Echo and Parley Canyon.

Some day perhaps this part of the country may be traversed without running into forbidding weather and road conditions. Up to now, however, it seems that each year the oldest residents rise up and state that never before in their memory have there been such cloudbursts, etc.

Slippery Alkali Mud

Naturally, we were not surprised that it had fallen to our lot to meet with adverse conditions. Just out of Salt Lake City we got acquainted with one of the worst rainstorms within the memory of man and were warned not to attempt to cross the Salt Lake desert at that time or within 24 hours after. We soon understood why this warning had been handed to us. For it was here that we got to learn what it means for any tourist to try and negotiate alkali mud during or just after a storm. This stuff is much different from gumbo, but we cannot say that it is any more welcome. It does not cling to the wheels and wrap itself around as gumbo does, but in another way it makes the going just as difficult. It is almost impossible to get traction in alkali mud. This stuff presents a shifting bottom. The car seems never able to get its wheels firmly planted.

After alkali mud becomes dry and hard it makes the best kind of a road, just as it is the worst kind of a road during or just after a rainstorm.

The elements continued to be against us, despite the fact that the alkali roads when dried were fairly good. The sun's rays now began to beat down and our trip across the desert was made with the thermometer from 120 to 130 degrees all the time. Generally there was not a breath of air stirring and when a wind did spring up it was one of those hot desert breezes that are just as bad as none at all. We must confess that we, the drivers, envied the car its ability to keep cool under these conditions. Every time we examined the radiator we found it not heated, even in the face of the trials placed upon it. Not once did we run out of water for the radiator, though at times we were 100 to 150 miles from habitation. As for gasoline, we always found the tank well enough filled to run from one supply station to another, despite the fact that these were often far separated. No reserve supply of gasoline was carried.

The Lincoln Highway skirts around the southern end of Salt Lake, which is on the edge of the Great Salt Lake desert. It also passes around several mountains. We made our way from Salt Lake City to Kanaka ranch, thence for 78 miles through the wilderness to Kearney's ranch.

From here we struck out for Eureka, Nev., a distance of 115 miles, where we checked in at 5 o'clock in the afternoon. We found the roads good between Ibapal and Eureka, but from Eureka on to Austin we had to cross Shelburn Pass, one of the highest summits in Nevada. Not only does Shelburn Pass provide a real test for the mountain-climbing ability of any car, but it is rocky in addition and consequently tries out thoroughly the frame, springs, axles, and other parts. This condition continued nearly all the way into Austin.

Turning Road Builders

Next we came face to face with the fact that getting a car from coast to coast involves more than the simple function of driving. The added duty of blazing a trail—of turning road builders—was forced upon us. For it was often necessary for us to climb out of the car and remove boulders of various sizes that otherwise would impede progress. Everybody who goes over this course has to do the very same thing, because boulders are always being tumbled down from the mountain sides.

Of all the summits in Nevada, the New Pass Mountain near Austin is considered the most difficult. This is a newly discovered mountain and to ascend it requires a 9-mile steady uphill climb, with the grade ranging between 10 and 24 per cent.—never less than 10 per cent. In crossing from one foothill to another we frequently came upon gullies that had once been river beds and since were dried up.

It was through this region that we came across a man who subsequently became a dealer. He had been figuring on handling our car, and upon hearing that the coast-to-coast machine was headed his way, he determined to see whether it could negotiate New Pass Mountain before closing the deal that was pending. The car performed the feat and the contract was closed.

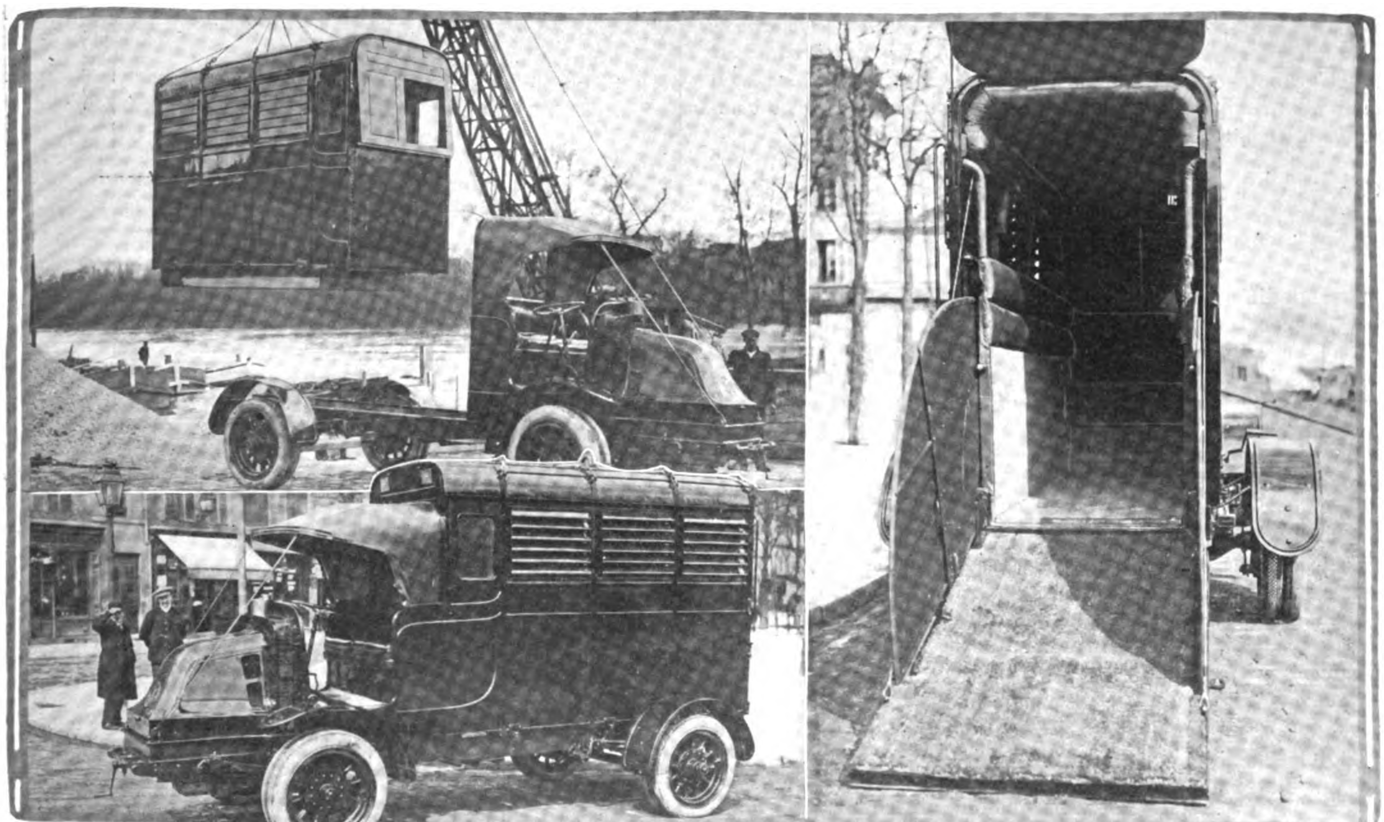
Two routes lead from Reno to Sacramento. The north route by way of the Truckee dam being closed to traffic because of snow slides, we went by the Southern route which led through Carson City and Placerville. After leaving Carson City we passed into King's Canyon, where there loomed up before us a summit of 6,940 feet—a continuous grade 6 1-2 miles in length with beautiful Lake Tahoe at the top. This was followed shortly after by the crossing of the Great Divide near Sacramento, and another sharp climb of 5,000 feet in four and one-half miles.

On the Home Stretch

We were now on the last leg of our 3,873 mile trip. But our troubles were not entirely over. For to offset the pleasure of driving through wonderful California we had to contend with the possibility of disaster, from the fact that we traveled many a mile at perilous, dizzy heights with only from one to three feet of road clearance. This was a time for the most careful driving, and a time when the car itself was placed on its mettle.

Finally, with this situation past, we put on a final burst of speed and with a run of 182 miles entered San Francisco on Independence Day, proceeded to the ocean's edge, drove the front wheels of the car into the Pacific, just as the rear wheels had been dipped into the Atlantic on June 4, and emptied into the Pacific a canteen of water carried all the way from the Atlantic.

A Novel Method for the Careful Transportation of Race Horses



BEING frequently obliged to send race horses from the training stables in France to the various race courses in England, Edmond Blanc, of Paris, France, has abandoned the railway in favor of a special motor service. Although the journey is not much more than 300 miles, of which 40 are by sea, it was found that the race horses sent by train invariably reached the course in poor condition. Under the motor service the horse is put in a special box at the training stables, the journey is made to Boulogne by road, at this port the horse box is lifted off the chassis and deposited on the deck of the steamer. On arrival at Folkestone the box is mounted on a similar chassis kept in readiness and the journey resumed by road direct to the course on which the horse is to run. The actual time spent from training stable to race course is less than by rail, and as the horse is not disturbed throughout the journey it arrives in good condition. This motor van is an ordinary Latil front drive chassis mounted on twin pneumatic tires.

Semi-Floating Axle Easy on Bearings

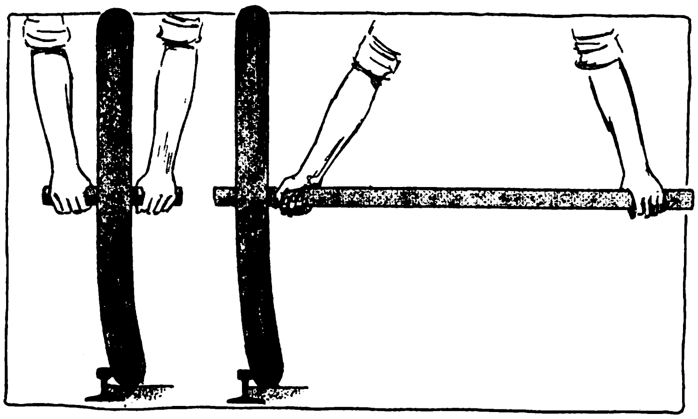


Fig. 1—Illustration to show the difference between the full and semi-floating axles when skidding. The latter has the mechanical advantage

When Skidding, Bearing Overload May Be 475 Per Cent With Full-Floating Axle — Stresses Due To Skidding Are More Important Than Those Due to Rolling

By Arthur M. Laycock, Chief Engineer, The Sheldon Axle Co.

EDITOR'S NOTE—In response to a letter signed by F. N. S., New Matamoras, O., asking THE AUTOMOBILE *to publish a discussion of the relative merits of the semi-floating and floating types of axles, requests were sent to several of the representative car and axle manufacturers asking them to give their views.*

Below is the reply of the Sheldon Axle Co., Wilkes-Barre, Pa., prepared by Arthur M. Laycock, chief engineer, dealing exhaustively with the subject. While the curves and diagrams may look forbidding to the average reader, it will be found that, although the subject is a technical one, it is so admirably presented that anyone should be able to comprehend it and derive benefit from it.

Replies from the Weston-Mott Co. and the Packard Motor Car Co. were presented in THE AUTOMOBILE *for July* 30 *and a paper from the Pierce-Arrow Motor Car Co. appeared in the issue for July* 23.

THE difference in stresses in the semi- and full-floating types is simply illustrated in Fig. 1. It would be absurd for anyone to attempt to hold a wheel straight up when rolling against a street car track, for instance, in the manner shown by the left illustration. The right one shows the only proper way to counteract these forces.

In other words, the bearing pressures, when skidding, are much less when the semi-floating axle is used; or, with the same factor of safety, smaller bearings may be used.

At the present time there are unquestionably many mistaken ideas concerning relative merits of the floating versus semi-floating construction as applied to the automobile, but it is rather difficult to convey to the reader an intelligent expression of these designs without resorting to higher mathematics.

Some of the illustrations, given herewith, are very simple in order to drive home the outstanding superiority of the semi-floating construction, particularly so when one takes as a base the forces acting on the side of the wheel instead of the straight static loads. One cannot attach too much importance to the advisability of working from this base.

It is utterly impossible to expect any trouble on general design from straight rolling loads, no matter how much they are overloaded, but the moment the wheel strikes a large cobblestone a glancing blow, brushes against the curb roughly, or even only side-skids on a good asphalt road, the pressures on the bearings and tubes are tremendously augmented.

Take a 5-ton truck with 25 per cent. overload on a country road where the ruts are rather deep, and observe the way

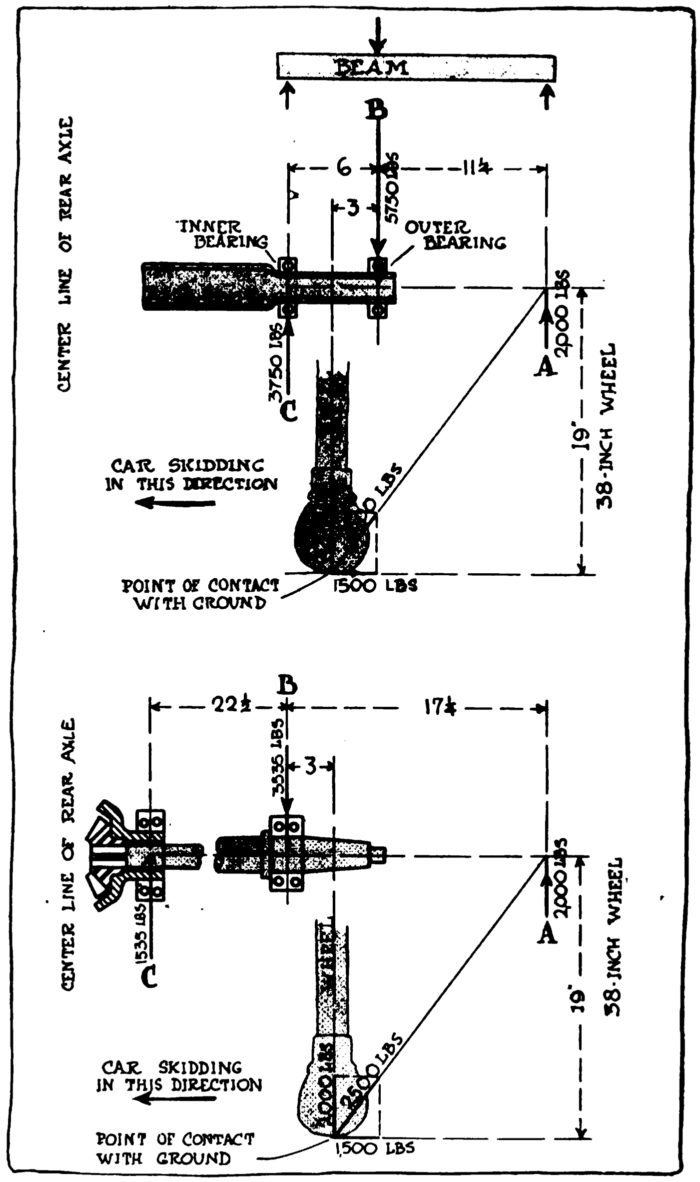

Fig. 2—Graphical method of determining the axle bearing stresses on semi and full-floating axles when skidding. It is assumed that the wheel load in both cases is 2,000 pounds. The wheels are 38 inches in diameter and the sketches of both axles are to scale. The full-floating axle is shown above, and the semi-floating below. A study of the text will show that the skidding of the wheel to the left, in the case of the full-floating axle, produces an upward stress of 3,750 pounds on the inner bearing C and one of 5,750 pounds at the outer bearing B. For simplicity it might be considered that these pressures were obtained by applying a force of 2,000 pounds at A, which is 11¼ inches from B. The accuracy of this assumption is proved by the graphical solution. In other words, the stresses at this point are similar to those acting on the beam at the very top.

the rear end will slew around from one rut to another. In some instances the whole dead weight is stopped in its side swing with the side of the rut. One can only imagine what enormous stresses are set up in these parts, even when only running from 12 to 15 miles per hour.

We will take the other extremes—the same 5-ton machine operating in the down-town districts where it is subjected frequently to turning corners at fair speed and skidding against the street car tracks and curbstones. It has been proven conclusively that these same machines have much more bearing and axle troubles than the ones that have to run on long straightaway runs to outlying districts, taking the same chassis and running under almost identical conditions, with this exception.

The writer has in mind a fleet of large trucks operating in Chicago at the present time, and this certainly proves beyond any shadow of a doubt that these forces are the only ones to take into consideration and not the static load action in a vertical direction on the axles.

Fig. 3 shows a very simple graphical method of comparing the two constructions.

It might be well to note in the first place that this is approximately a 1-ton rear axle with 2,000 pounds on the spoke line and that the full-floating design has a very liberal center-to-center distance for a 1-ton truck, which, of course, shows up this construction very much more favorably than if the center-to-center distance had been closer as in a good many existing designs.

Graphic Comparison of Stresses

The strains on the bearings when a car is skidding, compared graphically in Fig. 2, demonstrate that under the loading assumed, the outer bearing of the full floating type is subjected to a maximum load of 5,750 pounds while the corresponding bearing of the semi-floating type must carry a load of 3,535 pounds. At the same time the load on the inner bearing of the floating axle is 3,750 pounds, while the inner bearing of the semi-floating type carries a load of 1,535 pounds.

These results are arrived at by assuming that the weight resting on the 38-inch wheel is 2,000 pounds, as indicated, that the coefficient of friction between the tire and the road is 75 per cent. and that therefore if the car skids there will be a side thrust of .75 times 2,000 or 1,500 pounds. Therefore there are two forces acting at the rim of the wheel where it comes into contact with the ground. Assuming that the car is skidding to the left, then the thrust due to this is represented by a 1,500-lb. force in the opposite direction and then there is the upward reaction due to the weight. It is these two forces that must be resisted by the axle tubing.

Drawing a parallelogram of forces at the point of contact, the resultant or equivalent force acting at this point is seen to be 2,500 pounds and in the direction shown. The loads on the axle bearings can then be determined by projecting the resultant to the center line of the axle A extended, and reconstructing the parallelogram of forces it is seen that a 2,000-pound force applied at A, which is 11 1-4 inches from the center line of the wheel, will produce exactly the same strain as the 2,500-pound force applied at the point of contact of the wheel with the ground.

In order to find, in a simple manner, the stresses in the bearings at B and C, we may consider that we have a beam, Fig. 2, with loads placed at A, B and C. The load at A is 2,000 pounds, as already determined. Then the load on the inner bearing, considering that the bearing is pivoted at B, is

$$\frac{11\ 1\text{-}4 \times 2{,}000}{6} = 3{,}750 \text{ pounds}$$

To understand the above operation does not require a knowledge of mathematics. It is evident that with a load of 2,000 pounds 11 1-4 inches from the pivotal point or fulcrum, the bending moment is 2,000 x 11 1-4 and that a certain weight must be found on the other side to balance this, at a point 6 inches from this fulcrum. By the above simple calculation, it is found that this weight or force is 3,750 pounds.

Still keeping in mind that, to all intents and purposes, that we are dealing with a beam, we find that we have forces at A and C acting upward and that the one at B acts downward. If the axle is to maintain its equilibrium, the upward and downward forces must equal each other. Therefore, the force at B must be the sum of those at A and C, or 5,750 pounds.

Now, it is interesting to note that this pressure is as great as 5,750 pounds while a choice of bearing is undoubtedly made for 1,000 pounds, seeing that the vertical load on the spoke is 2,000 pounds for the two bearings, or you will notice under these conditions the outer bearing has an overload of 475 per cent.

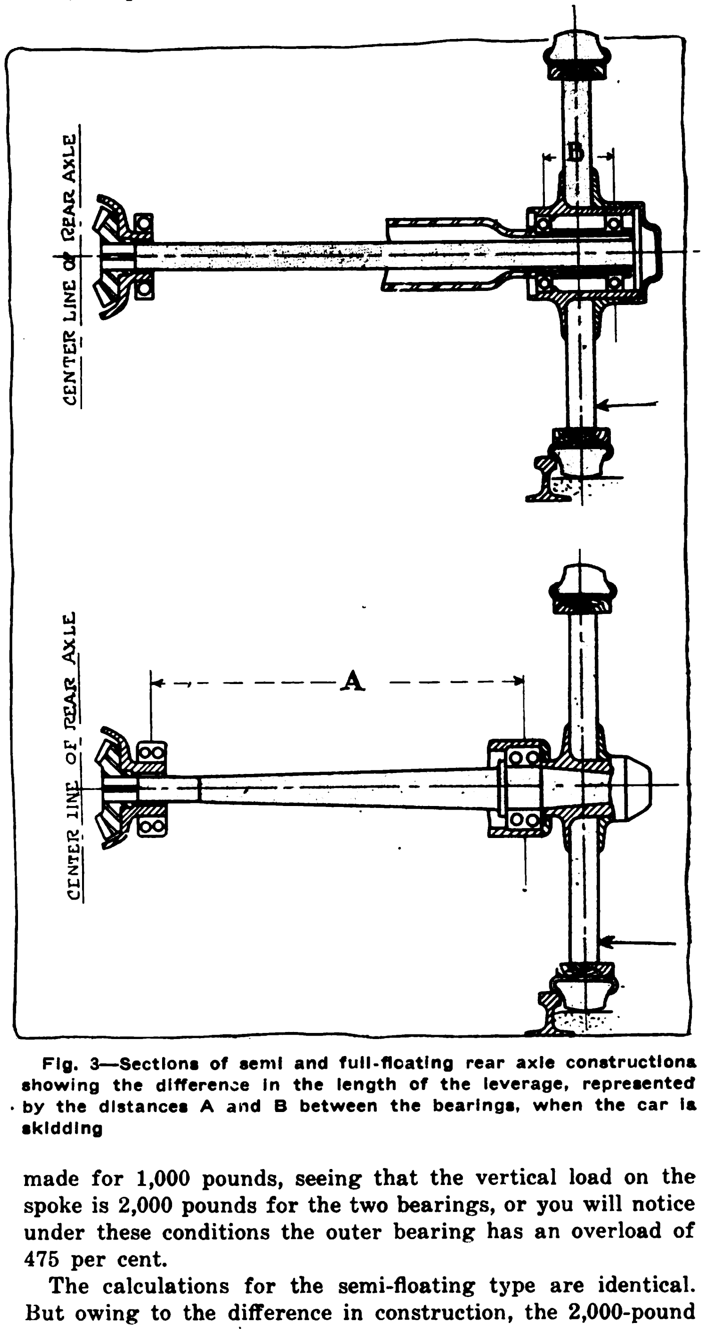

Fig. 3—Sections of semi and full-floating rear axle constructions showing the difference in the length of the leverage, represented by the distances A and B between the bearings, when the car is skidding

The calculations for the semi-floating type are identical. But owing to the difference in construction, the 2,000-pound force at A is 17 1-4 inches from the center line of the wheel. Further it will be noted that the bearing C is located at the differential instead of in the wheel hub. B is in exactly the same position, namely, 3 inches to the left of the center line of the wheel.

The load on the differential bearing is

$$\frac{2{,}000 \times 17\ 1\text{-}4}{22\ 1\text{-}2} = 1{,}535 \text{ pounds}$$

The load at B is the sum of the other two, or 3,535 pounds.

You will notice a very radical difference between this construction and the upper one inasmuch as the reactions are

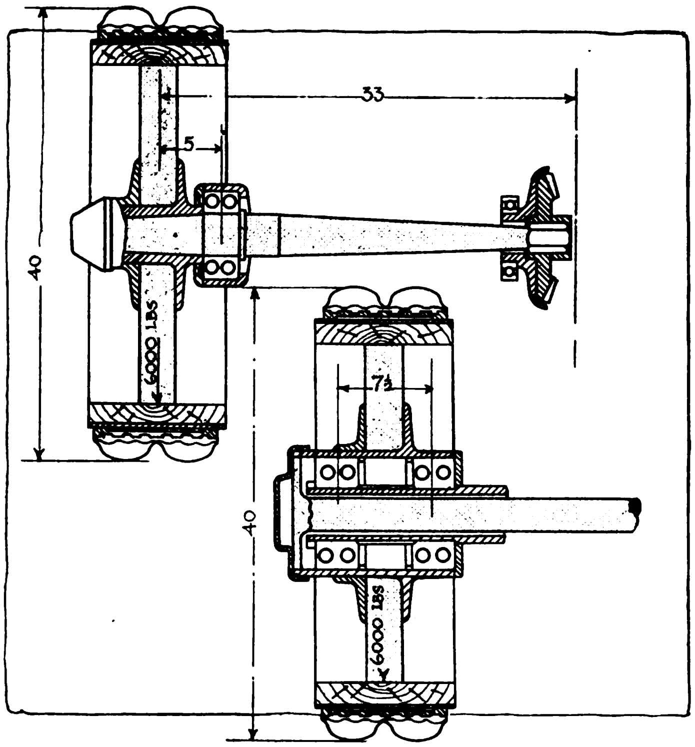

Fig. 4—Comparison of semi-floating and full-floating types from the viewpoint of bearing cost, both constructions having the same factor of safety. The dynamic load on the upper, which is a semi-floating construction, is 10,360, while the capacity of this bearing at 200 revolutions per minute is 17,000, that is, it is 64¼ per cent. stronger than actually required. The cost of these bearings is $19.50. In the full-floating type, which is the lower, the capacity of the bearing to have a factor of safety of 64¼ per cent. would need to be 15.910 times 64¼ plus 15,910, which equals 26,100 pounds. The cost of these bearings would be $76

taken on 22 1-2-inch centers against 6 inches on the floating type.

It is well to also notice that a choice of bearing would be made here for 2,000 pounds, which, of course, would give one a very much larger bearing.

Taking the bearing at its rated capacity, this bearing under these extreme conditions is only overloaded 76 per cent. against 475 per cent. on the floating, while the illustration as shown on Fig. 3 shows a fair balance in design for each construction, but with this great difference that the upper illustration can never withstand the same side pressures that the lower one can.

Building a full-floating type axle with the same factor of safety on the bearings as in the semi-floating, it would have to be in about the same scale as shown on Fig. 4.

You will notice in this diagram—which is self-explanatory—that the bearing cost is quite an item and one of the principal reasons the semi-floating has not had a larger following is from the fact that our leading axle manufacturers usually sell bearings as well.

Skidding Five Times Static Load

A good general idea as to the maximum loads on the bearings when side skidding, as compared to the static, can be obtained from the following example: The maximum load on a certain hub is 5,860 pounds. This, of course, is carried on two bearings—the inner and outer. This gives 2,930 pounds on each bearing, while, when side skidding, the outer one is subjected to a load of 15,085 pounds and the inner one to 15,910 pounds. This is approximately five times the static load.

Of course, these figures neglect sprocket pull, spoke and rim location and can only be used in a general way.

There are axles at the present time on the market with almost half the center-to-center distance of this particular one, and, instead of being five times the static, they approach ten times the static.

Turning now to Fig. 5, you will note that this particular driveshaft is well taken care of on the spoke line. It is purposely weakened at the inner end so that in case of failure you can always be brought home on the wheels. The semi-floating construction, as shown, may suffer in the same way, as the double side chain drive, when an axle breaks the truck is absolutely disabled and not able to get home. In designing an axle in this manner, the writer has never known an axle to break under the wheel. The particular shaft as shown on Fig. 6 is now used on a 3-ton worm-drive axle, and made from the very best steel procurable, and will unquestionably carry the loads it is designed for.

The stress as shown here is derived from a 50 per cent. overload with 80 per cent. on the rear, and even under these conditions, it will be impossible to break the axle on the spoke line.

Some of the fastest cars in the world have held tenaciously to this construction. Take, for instance, the Blitzen-Benz, and where the greatest possible strength for the least weight is desired one must of necessity take this construction, while one of our most popular 1 1-2-ton live axle drive trucks has given an excellent account of itself in real rough work. One of the most expensive cars built, the Pierce-Arrow, has used this constantly, even for the earliest designs. Taking the other extreme, the Ford, it would be impossible to design a rear axle construction stronger than this one for the same weight and price. These people must have had an early appreciation of the robust strength of this design.

It might be well to mention the three-quarter-floating, where the static load is taken on the tube and drive is taken through the shaft. This, of course, is in a class between the semi- and full-floating type. The popular erroneous idea with reference to the three-quarter-floating is in regard to the driveshaft being subjected to purely torsional strains, but it can be easily shown that the driveshaft is taking the combined bending and torsional strains as in the semi-float-

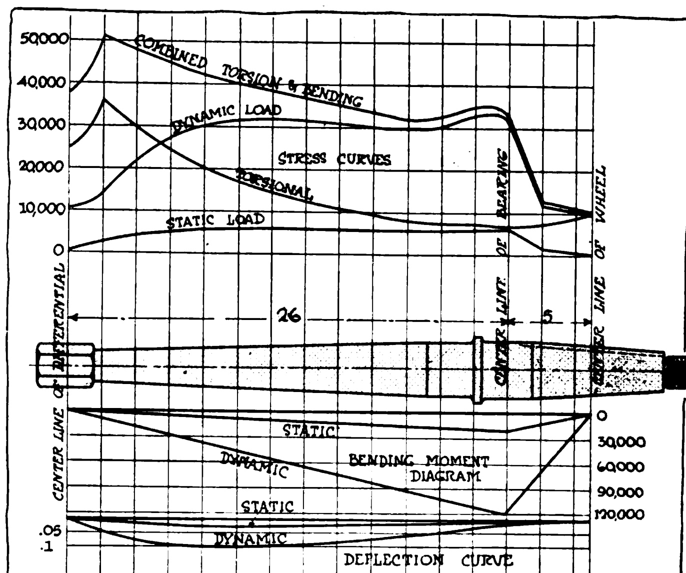

Fig. 5—Upper—Diagram showing combined bending and torsional strains at various points on an axle shaft when using a 40-inch wheel. It will be noted that there are four curves, the top one, which is marked combined torsion and bending, is a combination of the other three obtained by adding the ordinates. For instance, the static load at the extreme left ordinate is 1,000 pounds, the dynamic load is slightly over 11,000 pounds and the torsional load is about 25,000. Adding these three together the combined load at this point on the axle is about 37,000 pounds, which is correct. The static load is that bending moment which is produced by the weight on that wheel, the dynamic load that produced by skidding and the torsional load that caused by the twisting of the start when power is being transmitted

Fig. 6—Middle—Bending moment diagram. Lower—Deflection curves for bending moment diagram above

ing construction, and the only advantage the three-quarter would have over the semi-floating would be that you can take out the driveshafts without jacking up the car as in the floating type, but with this very great difference that the whole load is supported on one bearing momentarily, and if the car is standing on uneven ground the pressure on the end of the tube and bearing might be so great as to permanently injure it. Figuring that the driveshaft is a critical part of the construction, and taking into consideration that in order to have it safe it must have a very large diameter, when these dimensions are realized one has to add to this already liberal size twice the thickness of the tube plus the clearance, one can imagine the very large size of bearing that this particular construction entails, which, while it might be taken from the lighter series, entails such heavy housings, etc., as to make it undesirable from this view-point.

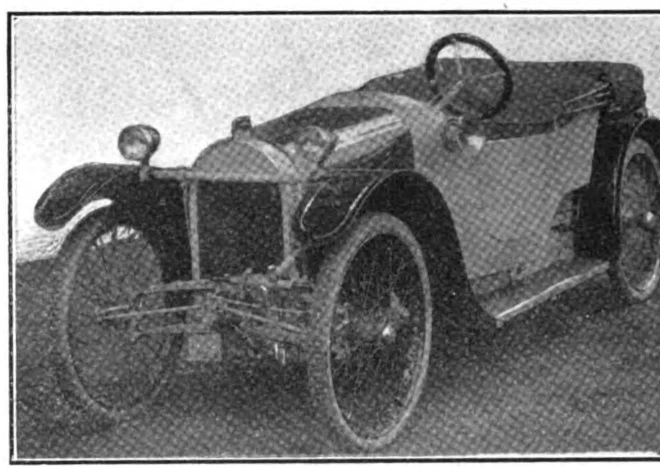
The writer has been repeatedly told that it has a further advantage of being able to get home on the one bearing in case of driveshaft failure. When this occurs on rough roads, it is an experience never to be forgotten, as it usually ends disastrously not only for the bearings but for the axle tube as well. The absence of support throws such a pinching action on the bearing that it is not long before it collapses entirely and brings the closure down on the tube, cutting off the tube and finally dropping the whole load.

The only disadvantage of the semi-floating construction is the inability to take the driveshaft out without jacking up the car. In some of the earlier types of axles it was exceedingly difficult to take them apart on account of first having to split the rear axle in order to release the inner end. Modern construction, of course, makes it comparatively easy to take out the differential when the side shafts are withdrawn, and all that is necessary on a nicely designed semi-floating construction axle is to jack up the rear end, undo two bolts on each hub, take out the differential; and the driveshafts can be taken out quite easily, but, due to the great factor of safety that a properly designed semi-floating construction insures, the axle is one of the last things to give trouble.

The writer has had considerable experience with this form of drive, and wherever the combined bending and torsion have been properly taken care of, he has yet to see a single failure at the wheel end, and in these days of lightweight construction, we prophesy that it will have a much larger following than in the past.

New Imp Has Four-Cylinder Water-Cooled Motor

IMP the Second is the name of the 1915 cyclecar announced by the W. H. McIntyre Co., Auburn, Ind. The new model of the Imp is quite a different car from the original Imp of 1914. It has a four-cylinder water-cooled motor instead of the two-cylinder V-type engine used in the earlier model. The friction drive is retained, but instead of final drive by V-belts a single roller chain is used, driving a live rear axle. The new Imp, instead of being a tandem seater, is now side-by-side, and in general appearance is like a standard roadster. It is stated that weight has been reduced considerably and many refinements incorporated. The motor has a bore and stroke of 2¾ by 4 inches with cylinders of the L-head type cast in block, and mounted on an aluminum crankcase. The motor is thermo-syphon cooled, and is oiled by splash assisted by a plunger pump. Both intake and exhaust manifold are cast integrally. Magneto ignition has been discarded and a unisparker substituted.



New Model Imp with water-cooled motor and chain drive

Gearless Differential Used

The rear axle incorporates a gearless differential whose main feature is said to be that it prevents skidding. The new Imp has left drive and is equipped with wire wheels, and 28 by 2 1-2-inch tires. The rack-and-pinion steering, double transverse semi-elliptic front springs and cantilever rear springs are retained.

The new side-by-side roadster body has artificial leather upholstering and the seat is 37 inches wide and 16 inches deep with a high back to make for comfortable riding. The fuel tank of the new Imp has a capacity of 5 gallons, and is located in the cowl. The Imp prices for 1915 are as follows: $395 including horn and electric light, $420 with top, curtains and folding windshield, and $495 completely equipped, including electric cranker and generator.

All models are thoroughly tested before they are packed for shipment.

C. A. C. Roadster Will Do Fifty

Fifty miles per hour is claimed for the C. A. C. roadster, a sporty-looking machine, with bucket seats resting on the floor, oval tank in the rear and raked steering column. It is manufactured by the Coey Motor Co., Chicago, Ill., and sells for $425. The motor is a four-cylinder, four-cycle, water-cooled type, with a bore of 2.75 inches and a stroke of 4 inches. A Berling magneto is fitted and thermo-syphon cooling is used. Power is transmitted to a three-speed gearbox by a cone clutch. These members are combined into one unit suspended at three points.

The frame is made of pressed steel with half-elliptic springs at the front and three-quarter elliptics at the rear. Double-acting brakes are fitted to the rear wheel drums. The steering is a rack-and-pinion type paced on the left. Center control is used. The equipment includes two large gas lamps and one oil tail lamp. A top is fitted for $25 additional.

Sporty looking C. A. C. roadster with four-cylinder water-cooled motor

Proper Temperature Is the Real Essential in Vulcanization

The Automobile Engineers' Forum

Source of Heat Is Immaterial, Says Vulcanizer Maker, Who Scores Theory That Moisture Enters Into Process—Automatic Temperature Control a Necessity To Prevent Burning of the Rubber—Regulation by Thermostat

WAUPUN, WIS.—Editor THE AUTOMOBILE:—Many car users seem to have the impression that the source of heat used in vulcanizers has something to do with the process of vulcanizing, in other words, that the nature of the heat, whether steam or electric, possesses some factors that share in the vulcanizing process.

Many statements have been circulated to the effect that steam is the only successful vulcanizing medium. They probably originated from the fact that tire manufacturers find steam to be the only convenient means of heating their huge vulcanizing devices to a uniform temperature. The idea has been fostered by a class of repair men who feared for their profits should the simplicity of the vulcanizing process become generally known.

As manufacturers of a complete line of portable vulcanizers for every requirement—some heated by electricity, others by steam, still others by radiation from a gasoline, or alcohol lamp, we feel that we can speak with the authority of absolute knowledge.

No Moisture Touches Tire

The supposed infallibility of steam vulcanizers has been attributed to the fact that they supplied a moist heat. The absurdity of this theory is apparent when it is considered that in no portable steam vulcanizer does any moisture come into contact with the tire. If it did the repair would very likely be spoiled. So at least an eighth of an inch of solid metal is between the steam and the tire. No scientific instrument is delicate enough to detect whether the surface of any vulcanizer is heated by steam or by some other source of heat.

Proper Temperature the Real Factor

The real essential to perfect vulcanization is the supplying of heat *at the proper temperature.* Automatic maintenance of the vulcanizing temperature is absolutely essential unless the operator of the vulcanizer wants to watch his vulcanizer and regulate its temperature by hand. Without an automatic temperature control there is nothing to prevent the temperature of confined steam from becoming high enough to burn rubber. If the steam is not confined it cannot become hot enough to vulcanize. Vulcanization occurs too slowly to be practicable at temperatures below 250 degrees Fahrenheit. Unconfined steam cannot be hotter than the boiling point of water, 212 degrees Fahrenheit.

The best results in vulcanizing are obtained only when the temperature is automatically maintained at a uniform degree throughout the time of curing.

Regulation by Thermostat

This automatic regulation of temperature is easily obtained by the use of a thermostat. Two strips of metal such as brass and steel are riveted together making a solid bar. When heat is applied the brass expands faster than the steel so that the bar bends. The amount of bend is proportionate to the temperature. The bar of thermostat is fastened to the vulcanizing surface in such a way that its bending either operates a damper in the flue of the steam vulcanizer, or regulates the amount of current flowing in an electric vulcanizer. Thus the temperature is automatically held exactly at the degree most suitable for vulcanizing without the operator having to give any thought to it.

No Learning Required

Anyone can use a vulcanizer of this sort without having to learn the vulcanizing business because nothing is left to his care except removing the vulcanizer from the tire when the repair has been finished.—C. A. SHALER CO.

Favors Single-Wire System To Prevent Cross-Connections

NEW YORK CITY—Editor THE AUTOMOBILE:—We are exceedingly in favor of the single-wire system, inasmuch as from very careful experimenting and research work we find it to be a much simpler and more reliable system than either the two or three-wire system. Also, it makes it practically impossible for the average layman to make any cross-connections.

This is one of the most important points which is borne in mind in the design of our single-wire fittings. A single-wire system, when properly installed, makes a neat appearance and looks very simple and from every point of view is more reliable than the multiple systems.—V. W. KLIESRATH, Chief Engineer, Bosch Magneto Co.

Uses Parabolic Lens of Golden Tint for Headlights
